# Final Santa Clara Valley Habitat Plan

Santa Clara County, California

County of Santa Clara  
City of San José  
City of Morgan Hill  
City of Gilroy  
Santa Clara Valley Water District  
Santa Clara Valley Transportation Authority

August 2012

# Final Santa Clara Valley Habitat Plan

August 2012

*Prepared for:*

City of Gilroy  
City of Morgan Hill  
City of San José  
County of Santa Clara  
Santa Clara Valley Transportation Authority  
Santa Clara Valley Water District

*Prepared by:*

ICF International

## Volume 1: Executive Summary, Acknowledgements, Table of Contents, and Chapters 1, 2, and 3

### Executive Summary

### Acknowledgements

<b>Chapter 1</b>	<b>Introduction.....</b>	<b>1-1</b>
1.1	Overview.....	1-1
1.1.1	Mission Statement .....	1-1
1.1.2	Purpose.....	1-3
1.1.3	Background.....	1-5
1.2	Scope of the Habitat Plan .....	1-6
1.2.1	Covered Activities .....	1-6
1.2.2	Geographic Scope .....	1-7
1.2.3	Permit Term .....	1-9
1.2.4	Covered Species.....	1-13
1.2.5	Relationship to the Proposed Three Creeks Habitat Conservation Plan.....	1-17
1.3	Regulatory Setting .....	1-18
1.3.1	Federal and State Endangered Species Laws.....	1-19
1.3.2	Other Federal and State Wildlife Laws and Regulations .....	1-24
1.3.3	National Environmental Policy Act .....	1-27
1.3.4	California Environmental Quality Act .....	1-27
1.3.5	Federal and State Wetland Laws and Regulations .....	1-28
1.3.6	National Historic Preservation Act .....	1-30
1.4	Overview of HCP/NCCP Planning Process .....	1-31
1.4.1	Organization of the Planning Process.....	1-31
1.4.2	Liaison Group.....	1-31
1.4.3	Stakeholder Group.....	1-32
1.4.4	Science Advisors .....	1-32
1.4.5	Management Team.....	1-33

1.4.6	Local Agency and Wildlife Agency Technical Coordination ...	1-34
1.4.7	Consultant Team.....	1-34
1.4.8	Public Outreach and Involvement .....	1-34
1.5	Document Organization .....	1-35
<b>Chapter 2</b>	<b>Land Use and Covered Activities.....</b>	<b>2-1</b>
2.1	Introduction .....	2-1
2.2	Land Use and Jurisdictions.....	2-1
2.2.1	Existing Conditions .....	2-1
2.2.2	Land Use Categories .....	2-20
2.2.3	Planning Limits of Urban Growth .....	2-23
2.2.4	Existing Open Space and Parkland .....	2-24
2.2.5	Protection and Resource Management Status of Open Space Lands .....	2-34
2.3	Covered Activities .....	2-36
2.3.1	Methods for Identifying Covered Activities .....	2-38
2.3.2	Urban Development .....	2-39
2.3.3	In-Stream Capital Projects .....	2-43
2.3.4	In-Stream Operations and Maintenance .....	2-69
2.3.5	Rural Capital Projects .....	2-84
2.3.6	Rural Operations and Maintenance .....	2-95
2.3.7	Rural Development .....	2-104
2.3.8	Conservation Strategy Implementation .....	2-107
2.4	Projects and Activities Not Covered by this Plan.....	2-112
<b>Chapter 3</b>	<b>Physical and Biological Resources .....</b>	<b>3-1</b>
3.1	Introduction .....	3-1
3.2	Physical Setting .....	3-2
3.2.1	Location .....	3-2
3.2.2	Topography .....	3-2
3.2.3	Geology.....	3-3
3.2.4	Soils .....	3-5
3.2.5	Climate and Hydrology.....	3-7
3.3	Ecosystems, Natural Communities, and Land Cover .....	3-14
3.3.1	Definitions .....	3-14
3.3.2	Methods .....	3-16
3.3.3	Covered Species.....	3-22
3.3.4	Biological Diversity of Study Area .....	3-29
3.3.5	Natural Communities and Land Cover Types .....	3-32

## Volume 2: Chapters 4, 5, and 6

<b>Chapter 4</b>	<b>Impact Assessment and Level of Take.....</b>	<b>4-1</b>
4.1	Introduction and Approach.....	4-1
4.2	Definitions.....	4-1
4.3	Impact Mechanisms.....	4-3
4.3.1	Urban Development .....	4-3

4.3.2	In-Stream Capital Projects .....	4-5
4.3.3	In-Stream Operations and Maintenance .....	4-21
4.3.4	Rural Capital Projects .....	4-33
4.3.5	Rural Operations and Maintenance .....	4-38
4.3.6	Rural Development .....	4-41
4.3.7	Conservation Strategy Implementation .....	4-43
4.4	Impact Assessment Methods.....	4-48
4.4.1	Direct Effects.....	4-49
4.4.2	Indirect Effects .....	4-64
4.5	Effects on Natural Communities/Land Cover.....	4-68
4.5.1	Direct Effects.....	4-68
4.5.2	Indirect Effects .....	4-69
4.6	Effects on Covered Species .....	4-72
4.6.1	Bay Checkerspot Butterfly .....	4-73
4.6.2	California Tiger Salamander, California Red-Legged Frog, Western Pond Turtle.....	4-80
4.6.3	Foothill Yellow-Legged Frog .....	4-86
4.6.4	Western Burrowing Owl .....	4-88
4.6.5	Least Bell's Vireo .....	4-92
4.6.6	Tricolored Blackbird .....	4-93
4.6.7	San Joaquin Kit Fox.....	4-95
4.6.8	Serpentine Plants.....	4-96
4.6.9	Non-Serpentine Plants.....	4-106
4.7	Effects on Critical Habitat .....	4-108
4.7.1	Bay Checkerspot Butterfly .....	4-108
4.7.2	California Tiger Salamander .....	4-110
4.7.3	California Red-Legged Frog.....	4-112
4.8	Cumulative Effects.....	4-113
4.8.1	Future Potential Development by the City of Gilroy .....	4-114
4.8.2	Ongoing and Routine Agriculture.....	4-115
4.8.3	Use of Existing Roads.....	4-116
4.8.4	Landfill or Quarries.....	4-116
<b>Chapter 5</b>	<b>Conservation Strategy .....</b>	<b>5-1</b>
5.1	Summary .....	5-1
5.2	Framework.....	5-2
5.2.1	Biological Goals and Objectives .....	5-3
5.2.2	Avoidance and Minimization Measures .....	5-8
5.2.3	Reserve System.....	5-9
5.2.4	Aquatic Habitat Protection and Enhancement .....	5-25
5.2.5	Land Management .....	5-26
5.2.6	Alternative Conservation Strategies.....	5-38
5.2.7	Data Sources .....	5-39
5.3	Conservation Actions.....	5-39
5.3.1	Land Acquisition and Restoration Actions .....	5-40
5.3.2	Landscape Conservation and Management .....	5-74
5.3.3	Grassland Conservation and Management .....	5-90
5.3.4	Chaparral and Northern Coastal Scrub Conservation and Management .....	5-99

5.3.5	Oak and Conifer Woodland Conservation and Management .....	5-104
5.3.6	Riverine and Riparian Forest and Scrub Conservation and Management .....	5-109
5.3.7	Wetland and Pond Conservation and Management .....	5-122
5.4	Benefits of and Additional Conservation Actions for Covered Species .....	5-134
5.4.1	Bay Checkerspot Butterfly .....	5-135
5.4.2	California Tiger Salamander .....	5-140
5.4.3	California Red-Legged Frog .....	5-147
5.4.4	Foothill Yellow-Legged Frog .....	5-151
5.4.5	Western Pond Turtle .....	5-154
5.4.6	Western Burrowing Owl .....	5-156
5.4.7	Least Bell's Vireo .....	5-165
5.4.8	Tricolored Blackbird .....	5-167
5.4.9	San Joaquin Kit Fox .....	5-170
5.4.10	Tiburon Indian Paintbrush .....	5-173
5.4.11	Coyote Ceanothus .....	5-175
5.4.12	Mt. Hamilton Thistle .....	5-180
5.4.13	Santa Clara Valley Dudleya .....	5-184
5.4.14	Fragrant Fritillary .....	5-186
5.4.15	Loma Prieta Hoita .....	5-189
5.4.16	Smooth Lessingia .....	5-191
5.4.17	Metcalf Canyon Jewelflower .....	5-195
5.4.18	Most Beautiful Jewelflower .....	5-199
<b>Chapter 6</b>	<b>Conditions on Covered Activities and Application Process .....</b>	<b>6-1</b>
6.1	Introduction .....	6-1
6.2	Exemptions from Conditions .....	6-2
6.3	Conditions on All Covered Activities .....	6-5
6.4	Conditions on Specific Covered Activities .....	6-8
6.4.1	Urban Development .....	6-8
6.4.2	In-Stream Projects .....	6-13
6.4.3	In-Stream Operations and Maintenance .....	6-18
6.4.4	Rural Projects .....	6-21
6.4.5	Rural Operations and Maintenance .....	6-34
6.4.6	Reserve System Implementation .....	6-37
6.5	Conditions to Minimize Impacts on Natural Communities .....	6-44
6.6	Conditions to Minimize Impacts on Specific Covered Species .....	6-61
6.6.1	Selected Covered Wildlife Species .....	6-62
6.6.2	Covered Plant Species .....	6-73
6.7	Receiving Take Authorization under the Plan .....	6-80
6.7.1	Evaluation Process for Permittee Projects .....	6-80
6.7.2	Application Process for Private Projects .....	6-82
6.7.3	Application Process for Non-Permittee Public Projects .....	6-84
6.8	Habitat Plan Application Package .....	6-84
6.8.1	Item 1: Project Application Form .....	6-86
6.8.2	Item 2: Project Description and Map .....	6-86
6.8.3	Item 3: Land Cover Types on Site .....	6-86

6.8.4	Item 4: Map of Wetlands, Ponds, Streams, and Riparian Woodlands .....	6-89
6.8.5	Item 5: Results of Applicable Species Surveys and Monitoring .....	6-90
6.8.6	Item 6: Compliance Documentation .....	6-96
6.9	Confirming Exemption from the Plan .....	6-97

## Volume 3: Chapters 7 through 13

<b>Chapter 7</b>	<b>Monitoring and Adaptive Management Program .....</b>	<b>7-1</b>
7.1	Introduction .....	7-1
7.1.1	Regulatory Context .....	7-1
7.1.2	Adaptive Management .....	7-2
7.1.3	Program Objectives .....	7-5
7.1.4	Program Scope .....	7-5
7.1.5	Take Authorization during Monitoring .....	7-9
7.2	Overview .....	7-9
7.2.1	Types of Monitoring .....	7-9
7.2.2	Program Phases .....	7-14
7.2.3	Program Implementation .....	7-20
7.2.4	Guidelines for Monitoring .....	7-25
7.3	Monitoring and Management Actions .....	7-30
7.3.1	Landscape-Level Actions .....	7-30
7.3.2	Natural Community-Level Actions .....	7-34
7.3.3	Species-Level Actions .....	7-47
7.4	Data and Reporting .....	7-83
<b>Chapter 8</b>	<b>Plan Implementation .....</b>	<b>8-1</b>
8.1	Overview .....	8-1
8.2	Implementation Structure .....	8-1
8.2.1	Permittees .....	8-2
8.2.2	Implementing Entity .....	8-3
8.2.3	Other Land and Water Management Agencies .....	8-5
8.2.4	Technical Advisory Committee .....	8-5
8.2.5	Wildlife Agencies .....	8-6
8.2.6	Scientific Review .....	8-8
8.2.7	Public Input .....	8-9
8.3	Responsibilities of the Implementing Entity .....	8-10
8.3.2	Administrative Director .....	8-13
8.3.3	Science .....	8-14
8.3.4	Real Estate Activities .....	8-14
8.3.5	Grant Administration .....	8-14
8.3.6	Budget Analysis .....	8-15
8.3.7	GIS/Database Maintenance .....	8-15
8.3.8	Reserve Management and Monitoring .....	8-15
8.3.9	Public Outreach and Education .....	8-17
8.3.10	Legal and Financial Services .....	8-17
8.3.11	Consultants and Contractors .....	8-18
8.3.12	Responsibilities of the Local Jurisdictions .....	8-18

8.4	Participating Special Entities .....	8-19
8.4.1	San Martin.....	8-21
8.5	Local Implementing Ordinances .....	8-21
8.6	Land Acquisition .....	8-22
8.6.1	Stay-Ahead Provision .....	8-24
8.6.2	Land Acquired by Other Organizations or through Partnerships.....	8-31
8.6.3	Conservation Easements.....	8-34
8.6.4	Grazing Leases, Licenses or Contracts within the Reserve System.....	8-38
8.6.5	Willing Sellers .....	8-40
8.6.6	Gifts of Land.....	8-41
8.6.7	Land Dedication In Lieu of Development Fee .....	8-41
8.6.8	Williamson Act Parcels .....	8-43
8.7	Roles and Responsibilities in Reviewing Applications for Take Authorization.....	8-43
8.7.1	Permittee Responsibilities.....	8-43
8.7.2	Implementing Entity Responsibilities .....	8-44
8.7.3	Wildlife Agency Responsibilities .....	8-45
8.8	Three Creeks HCP .....	8-47
8.8.1	Implementation Structure.....	8-48
8.8.2	Adaptive Management .....	8-48
8.9	Implementing Agreement.....	8-49
8.10	Data Tracking .....	8-49
8.10.1	Database Development and Maintenance.....	8-49
8.10.2	Compliance Tracking .....	8-51
8.11	Reporting .....	8-53
8.12	Schedule and Deadlines.....	8-56
<b>Chapter 9</b>	<b>Costs and Funding .....</b>	<b>9-1</b>
9.1	Introduction.....	9-1
9.2	Cost to Implement the Habitat Plan.....	9-1
9.3	Cost Estimate Methodology.....	9-2
9.3.1	Land Acquisition.....	9-3
9.3.2	Reserve Management and Maintenance (Including Adaptive Management).....	9-5
9.3.3	Habitat Restoration, Creation, and Covered Plant Occurrence Creation.....	9-11
9.3.4	Monitoring, Research, and Scientific Review.....	9-13
9.3.5	Program Administration .....	9-14
9.3.6	Contingency .....	9-17
9.3.7	Costs in Perpetuity.....	9-18
9.4	Funding Sources and Assurances.....	9-19
9.4.1	Habitat Plan Development Fees .....	9-20
9.4.2	Local Funding .....	9-46
9.4.3	State and Federal Funding .....	9-51
9.4.4	Funding Adequacy .....	9-54

<b>Chapter 10</b>	<b>Assurances .....</b>	<b>10-1</b>
10.1	Introduction .....	10-1
10.2	Assurances Requested by Permittees.....	10-1
10.2.1	Changed and Unforeseen Circumstances .....	10-1
10.2.2	Federal No Surprises .....	10-21
10.2.3	Federal Section 7 Consultations .....	10-22
10.2.4	State NCCP Assurances.....	10-22
10.2.5	Conservation Contributions by State and Federal Agencies .....	10-23
10.2.6	Staff Contributions by State and Federal Agencies .....	10-23
10.2.7	Assurances for Private Landowners .....	10-24
10.3	Modifications to the Plan.....	10-28
10.3.1	Administrative Changes .....	10-28
10.3.2	Minor Modification.....	10-29
10.3.3	Amendments.....	10-32
<b>Chapter 11</b>	<b>Alternatives to Take.....</b>	<b>11-1</b>
11.1	Alternatives to Take of Bay Checkerspot Butterfly .....	11-2
11.2	Alternatives to Take of California Red-Legged Frog.....	11-3
11.3	Alternatives to Take of California Tiger Salamander .....	11-5
11.4	Alternatives to Take of Foothill Yellow-Legged Frog .....	11-7
11.5	Alternatives to Take of Western Pond Turtle .....	11-8
11.6	Alternatives to Take of Least Bell's Vireo .....	11-9
11.7	Alternatives to Take of Western Burrowing Owl .....	11-11
11.8	Alternatives to Take of Tricolored Blackbird .....	11-12
11.9	Alternatives to Take of San Joaquin Kit Fox.....	11-13
<b>Chapter 12</b>	<b>List of Preparers .....</b>	<b>12-1</b>
12.1	Land Use Planning Services.....	12-1
12.2	ICF International .....	12-1
12.2.1	HCP/NCCP Team .....	12-1
12.2.2	Public Outreach Team .....	12-2
12.3	Willdan Financial Services.....	12-2
12.4	Hausrath Economics Group.....	12-2
12.5	Resources Law Group .....	12-2
12.6	MIG.....	12-2
12.7	Additional Consultants .....	12-2
<b>Chapter 13</b>	<b>Literature Cited .....</b>	<b>13-1</b>

## **Volume 4: Appendices**

- Appendix A Glossary**
- Appendix B Implementing Agreement**
- Appendix C Evaluation of Special-Status Species for Coverage in the Santa Clara Valley HCP/NCCP**
- Appendix D Species Accounts**
- Appendix E Nitrogen Deposition Contribution Estimates**
- Appendix F Climate Change Analysis**
- Appendix G Cost Model**
- Appendix H Conservation Easement Template**
- Appendix J Monitoring at Different Levels**
- Appendix K California Tiger Salamander Hybridization**
- Appendix L Fish Habitat Assemblage Data**
- Appendix M Western Burrowing Owl Conservation Strategy**
- Appendix N Burrowing Owl Population Viability Analysis  
Santa Clara Valley Habitat Conservation Plan/Natural  
Communities Conservation Plan (HCP/NCCP)—  
March 2010**
- Appendix O List of Acronyms and Abbreviations**

# Tables

## At End of Each Section

ES-1	Covered Species
ES-2	Summary Evaluation of Species Proposed for Coverage by the Santa Clara Valley Habitat Plan
ES-3	Habitat Plan Cost and Funding Overview
1-1	Local Planning Documents and Time Horizons Relevant to the Permit Term
1-2	Species Proposed for Coverage in the Santa Clara Valley Habitat Plan
1-3	Checklist for NCCP Act Requirements
2-1	Proposed Land Use Categories and Associated General Plan Land Use Designations
2-2	Significant Open Space or Parkland Areas within the Study Area
2-3	Examples of Open Space Types in the Study Area
2-4	Dry and Wet Season Maximum and Minimum Covered Reservoir Dewatering Flows for SCVWD Reservoirs for the Purpose of Triggering Additional Wildlife Agency Approval Requirements
2-5	Existing Interim Storage Restrictions for SCVWD Dams
2-6	Specific Transportation Projects that are Covered by the Plan
3-1	Natural Community Classification and Land Cover Types
3-2	Crosswalk of Land Cover Classification to Other Classification Systems
3-3a	Counts of Polygons of Field-Checked Land Cover Types in Valley Floor
3-3b	Amounts of Field-Checked Land Cover Types (Acres) in Valley Floor
3-4	Uncertainties in Land Cover Mapping, by Land Cover Type
3-5	Covered Wildlife Species and Their Associated Land Cover Types
3-6	Covered Plant Species and Land Cover Types
3-7	Land Cover Types and their Extent in the Study Area
3-8	Native Fish and Amphibian Species in Relation to Fish Communities in Santa Clara County Streams
4-1	Potential Indirect Adverse Impacts on Covered Species from New Urban and Rural Development and Operation of the Habitat Plan Reserve System
4-2	Total Allowable Permanent Impacts on Land Cover Types and Natural Communities (acres)
4-3	Total Allowable Temporary Impacts on Land Cover Types and Natural Communities (acres)

- 4-4 Maximum Allowable Permanent and Temporary Impacts to Covered Species Modeled Habitat
- 4-5a In-Stream Capital Improvement Project Permanent Impact Estimation Methods and Key Assumptions
- 4-5b In-Stream Capital Improvement Project Construction Temporary Impact Estimation Methods and Key Assumptions
- 4-5c In-Stream Operations and Maintenance Temporary Impact Estimation Methods and Key Assumptions
- 4-5d Rural Capital Improvement Project Permanent Impact Estimation Methods and Key Assumptions
- 4-5e Rural Capital Improvement Project Construction Temporary Impact Estimation Methods and Key Assumptions
- 4-5f Rural Operations and Maintenance Temporary Impact Estimation Methods and Key Assumptions
- 4-5g Reserve System Permanent Impact Estimation Methods and Key Assumptions
- 4-5h Reserve System Construction Temporary Impact Estimation Methods and Key Assumptions
- 4-6 Covered Plant Occurrences and Estimated Permanent Impacts from Covered Activities
- 4-7 Assumptions of Land Cover Imperviousness
- 4-8 Results of Impervious Surface Analysis
- 4-9 Estimated Impacts to Critical Habitat
- 5-1a Biological Goals, Objectives, and Conservation Actions: Landscape Level
- 5-1b Biological Goals, Objectives, and Conservation Actions: Natural Community Level
- 5-1c Biological Goals, Objectives, and Conservation Actions: Wildlife
- 5-1d Biological Goals, Objectives, and Conservation Actions: Plants
- 5-2a Land Acquisition Actions
- 5-2b Land Management Actions
- 5-3 Guidelines Used to Set Quantitative Objectives for Species Habitat Protection in the Absence of Species-Specific Data
- 5-4 Gap Analysis for Land Cover Types (acres)
- 5-5 Existing Open Space and Interim Conservation Lands Proposed for the Reserve System and Specific Conservation Actions within Each Site
- 5-6 Gap Analysis for Covered Species with Habitat Distribution Models (acres)
- 5-7 Gap Analysis of Bay Checkerspot Butterfly Populations (acres)
- 5-8 Gaps in Conservation Identified by San Francisco Bay Area Gap Analysis Project for Land Cover Types in the Habitat Plan Study Area

- 5-9 Landscape Linkages in and Near the Study Area Considered for the Reserve Design
- 5-10 Conservation Analysis Zones and Land Cover Types (acres)
- 5-11 Land Acquisition and Enhancement Requirements within the Study Area for Selected Terrestrial Land-Cover Types (acres)
- 5-12 Required Preservation, Enhancement, Restoration and Creation Mitigation Ratios and Estimated Acquisition, Enhancement, Restoration, and Creation Requirements for Aquatic Land Cover Types
- 5-13 Acquisition, Restoration, and Creation Requirements for all Land-Cover Types (acres)
- 5-14 Commitments by Time Period for Restoration and Creation Requirements that Contribute to Species Recovery
- 5-15 Minimum Distance from Urban Development Required for Aquatic Land Cover Types to Count Toward Land Acquisition or Restoration/Creation Requirements
- 5-16 Species Occurrences, Impacts, and Conservation Requirements for Covered Plants
- 5-17 Commitments to Acquire and Enhance Modeled Habitat in the Reserve System for Covered Species with Models (acres)
- 5-18 Land Acquisition and Enhancement Requirements for Selected Conservation Analysis Zones (acres)
- 5-19 Land Acquisition and Enhancement Requirements for Serpentine Grassland in the Study Area
- 5-20 Management Consideration for Significant Invasive Plants in the Plan Area
- 5-21 Protected Critical Habitat Units
- 6-1 Covered Activities Exempt from Plan Conditions and/or Plan Fees
- 6-2 Aquatic Avoidance and Minimization Measures
- 6-3 Conditions on Covered Transportation Projects
- 6-4 Rural Road Maintenance Avoidance and Minimization Measures
- 6-5 Habitat for Covered Species Avoided due to the Stream and Riparian Setback Condition
- 6-6 Recommended Setbacks to Preserve Riparian and Stream Function (from studies throughout the United States since 1990)
- 6-7 Required Stream Setback Distances
- 6-8 Summary of Habitat Survey Requirements and Preconstruction Survey and Monitoring for Select Covered Wildlife Species
- 6-9 Survey Periods for Covered Plant Species
- 7-1 Schedule of Monitoring Tasks over the Permit Term
- 7-2 Example Success Criteria for Monitoring Effectiveness of Selected Management Actions

8-1	Schedule for Major Implementation Tasks
8-2	Key Deadlines for Plan Compliance
9-1	Summary of Habitat Plan Implementation Cost Estimate
9-2	Santa Clara Valley Habitat Plan Reserve System Summary
9-3	Summary of Annual Management and Monitoring Costs per Acre
9-4	Summary of Habitat Plan Budget After Permit Term
9-5	Funding Sources
9-6	Land Cover Development Fees
9-7a	Habitat Plan Land Cover Development Fees and Estimated Revenue
9-7b	Habitat Plan Nitrogen Deposition Fee and Estimated Revenue
9-8	Endowment Fee Calculations
9-9	Plan Preparation Cost Recovery Fee Calculations
9-10	Habitat Plan Nitrogen Deposition Fee Calculation
9-11	Wetland Fees by Land Cover Type
9-12	Fee Adjustment Indices
9-13	Federal and State Funding Sources for HCPs and NCCPs in California
10-1	Thresholds and Remedial Actions for Changed and Unforeseen Circumstances Addressed by the Plan
10-2	Natural Community-Specific Fire Return Intervals
10-3	Modeled Habitat for Eligible Covered Species found on Eligible Neighboring Lands

# Figures

## At End of Each Section

- 1-1 Regional Location of the Habitat Plan Study Area
- 1-2 Santa Clara Valley Habitat Plan Study Area and Permit Area
- 1-3 FAHCE Program Boundary
- 2-1 Santa Clara Valley Water District Water Conveyance, Treatment, and Distribution System
- 2-2 Santa Clara Valley Habitat Plan Land Use Categories
- 2-3 Open Space Categories in the Santa Clara Valley Habitat Plan Study Area
- 2-4 Decision Tree and Criteria for Existing Open Space Classification
- 2-5 Private Development Areas Subject to the Plan
- 2-6 SCVWD Capital Projects
- 2-7 Rural Transportation Projects
- 3-1 Santa Clara Valley HCP/NCCP Topography
- 3-2 Santa Clara Valley HCP/NCCP Slope in Degrees
- 3-3 Soils in the Santa Clara Valley HCP/NCCP Area
- 3-4 Santa Clara Valley HCP/NCCP Serpentine Areas
- 3-5 Average Annual Rainfall in HCP/NCCP Study Area
- 3-6 Santa Clara Valley HCP/NCCP Watersheds
- 3-7 Coyote Creek Historic and Current Mean Monthly Flows below Anderson Dam
- 3-8 Santa Clara Valley Habitat Plan Natural Communities and USDA Ecoregion Subsections
- 3-9 Santa Clara Valley Habitat Plan Natural Communities
- 3-10 Santa Clara Valley Habitat Plan Land Cover
- 3-11 Extent of Grazing in the Study Area
- 3-12 Fish Communities in the Study Area
- 3-13 Pond Density in the Study Area
- 4-1 Rural Development Zones Used in the Impact Analysis
- 4-2 Habitat Plan Watersheds Assessed for Impervious Surface Analysis
- 4-3 Illustration of Burrowing Owl Take Allowance
- 4-4 Bay Checkerspot Butterfly Critical Habitat within the Study Area
- 4-5 California Tiger Salamander Critical Habitat within the Study Area

4-6	California Red-legged Frog Critical Habitat within the Study Area
5-1	Conceptual Model and Conceptual Approach to the Conservation Strategy for the Santa Clara Valley Habitat Plan
5-2	Structure of the Biological Goals and Objectives
5-3	Relationship of Biological Goals and Objectives to Adaptive Management and Monitoring
5-4	Existing Open Space and Interim Conservation Proposed for the Reserve System
5-5	Conservation Analysis Zones
5-6	Potential Landscape Linkages in and Near the Study Area
5-7	Land Acquisition Strategy
5-8	Land Acquisition Strategy with Applicable Landscape Linkages
5-9a	Permeability along U.S. 101
5-9b	Permeability along Highway 152
5-10	Expanded Study Area for Burrowing Owl Conservation
5-11	Burrowing Owl Conservation Strategy - Habitat Types
6-1	Schematic for Calculating Development Area

# Executive Summary

## Overview

The Santa Clara Valley Habitat Plan (Plan) provides a framework for promoting the protection and recovery of natural resources, including endangered species, while streamlining the permitting process for planned development, infrastructure, and maintenance activities. The Plan will allow the County of Santa Clara (County), the Santa Clara Valley Water District (SCVWD), the Santa Clara Valley Transportation Authority (VTA) and the cities of Gilroy, Morgan Hill, and San José (collectively, the Local Partners or Permittees) to receive endangered-species permits for activities and projects they conduct and those under their jurisdiction. The Santa Clara Valley Open Space Authority (Open Space Authority) has also contributed to Plan preparation. The Plan will protect, enhance, and restore natural resources in specific areas of Santa Clara County and contribute to the recovery of endangered species. Rather than separately permitting and mitigating individual projects, the Plan evaluates natural-resource impacts and mitigation requirements comprehensively in a way that is more efficient and effective for at-risk species and their essential habitats.

This Plan was developed in association with the U.S. Fish and Wildlife Service (USFWS), and the California Department of Fish and Game (CDFG), and in consultation with stakeholder groups and the general public. The Permittees are asking the USFWS to issue them a 50-year permit that authorizes incidental take<sup>1</sup> of listed species under the federal Endangered Species Act (ESA). The Permittees are also asking CDFG to issue to them a 50-year permit that authorizes take<sup>2</sup> of all covered species under the Natural Community Conservation Planning Act (NCCP Act). This approach will allow the Permittees to streamline future mitigation requirements into one comprehensive program. In addition to obtaining take authorization for each participating agency's respective activities, the cities and County will be able to extend take authorization to project applicants under their jurisdiction.

USFWS and CDFG (collectively the Wildlife Agencies) will also provide assurances to the Permittees that no further commitments of funds, land, or water

---

<sup>1</sup> *Take*, as defined by the Endangered Species Act, means “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct.” *Harm* is defined as “any act that kills or injures the species, including significant habitat modification.”

<sup>2</sup> *Take* is defined under the California Fish and Game Code as any action or attempt to “hunt, pursue, catch, capture, or kill.”

will be required to address impacts on covered species beyond that described in the Plan to address changed circumstances.

In addition to strengthening local control over land use and species protection, the Plan will provide a more efficient process for protecting natural resources by creating new habitat reserves that will be larger in scale, more ecologically valuable, and easier to manage than the individual mitigation sites created under the current approach.

## Geographic Scope

The study area (519,506 acres) is located in Santa Clara County in the central California Coast Range. The primary valley in the study area is the Santa Clara Valley, which stretches from San Francisco Bay to San Benito County. The Santa Clara Valley is bounded on the east by the Diablo Range, on the west by the Santa Cruz Mountains, and on the north by the San Francisco Bay shoreline. The study area was defined as the area in which covered activities will occur, impacts will be evaluated, and the majority of Plan conservation activities will be implemented. Some conservation actions for western burrowing owl will occur in the northern portion of the County in an area referred to as the expanded study area for burrowing owl conservation. The boundary of the study area was based on political, ecological, and hydrologic factors. The study area excludes tidally influenced portions of the Baylands. See **Figures 1-1 and 1-2** for maps of the study area, which covers 62% of the county.

The Santa Clara Valley is generally split into two geographic regions, the North Valley and the South Valley. The North Valley is extensively urbanized and is home to almost all of the County's residents. Thirteen of the County's fifteen cities are located in the North Valley, while the remaining two cities, Gilroy and Morgan Hill, are located in the South Valley. The South Valley remains predominantly rural, with the exception of Gilroy, Morgan Hill, small unincorporated community of San Martin, and scattered residential areas generally having parcels of five acres or less. Low-density residential developments are also scattered along the Valley floor and foothill areas. Almost the entire city of San José lies within the study area.

## Permit Term

The permit term is the time period in which all covered activities can receive take authorization under the Plan, consistent with the requirements of the Plan. The permit term is also the time in which all conservation actions must be successfully completed to offset the impacts of the covered activities. The Permittees will request permits from CDFG and USFWS. Each permit will be issued to all Permittees collectively. These permits will be tied to this Plan and to the Implementing Agreement. The Local Partners are seeking permits from the Wildlife Agencies with terms of 50 years. The permit term of 50 years was

selected because it allows for the full and successful implementation of the covered activities, the conservation strategy, the monitoring and adaptive management program, and the funding strategy.

## Covered Activities

A primary goal of this Plan is to obtain authorization for incidental take of covered species under the ESA and the NCCP Act for specific activities, called covered activities, which will occur in accordance with approved land-use and capital-improvement plans. Covered activities in the Plan fall into seven general categories.

- Urban development.
- In-stream capital projects.
- In-stream operations and maintenance.
- Rural capital projects
- Rural operations and maintenance
- Rural development
- Conservation strategy implementation (i.e., activities within the lands managed, enhanced, restored, and monitored to conserve the natural resources targeted by this Plan).

## Covered Species

This Plan provides take authorization for 18 listed and non-listed species (i.e., covered species) (**Table ES-1**). The 18 covered species were identified from a larger pool of 148 species in the region that are listed or that could become listed during the permit term. Species were selected for coverage based on their potential to be affected by covered activities, their occurrence in the study area, the adequacy of data for the species, and the species' current or foreseeable listing status. The Plan includes conservation measures to protect all 18 species selected for coverage under the Plan, whether or not they are currently listed. Accordingly, should any non-listed, covered species become listed during the permit term, additional conservation measures will not be required.

**Table ES-1. Covered Species**

<b>Invertebrates</b>	<b>Plants</b>
Bay checkerspot butterfly	Tiburon Indian paintbrush
<b>Amphibians and Reptiles</b>	Coyote ceanothus
California tiger salamander	Mount Hamilton thistle
California red-legged frog	Santa Clara Valley dudleya
Foothill yellow-legged frog	Fragrant fritillary
Western pond turtle	Loma Prieta hoita
<b>Birds</b>	Smooth lessingia
Western burrowing owl	Metcalf Canyon jewelflower
Least Bell's vireo	Most beautiful jewelflower
Tricolored blackbird	
<b>Mammals</b>	
San Joaquin kit fox	

## Conservation Strategy

The conservation strategy was designed to mitigate impacts on covered species and to contribute to the recovery of these species in the study area. The conservation strategy provides for the protection and enhancement of natural resources at multiple scales including landscape, natural-community, and species-specific levels.

The conservation strategy is based on a set of biological goals and objectives developed specifically for the Plan. Conservation actions were then identified to achieve these goals and objectives. The conservation strategy consists of the following major components:

- the acquisition of land and the creation of a Reserve System, including regional connections between protected areas;
- the long-term management, enhancement, and in some cases restoration of natural communities within the Reserve System;
- the development of a comprehensive aquatic conservation strategy to address the needs of covered amphibians and aquatic reptiles;
- the implementation of a comprehensive, long-term, adaptive management and monitoring program; and
- the implementation of avoidance and minimization measures on covered activities (called conditions on covered activities).

The general level of conservation effort for each covered species and natural community was determined by four broad criteria, namely:

- amount of impact from covered activities;

- proportion of the species' range or uniqueness of natural community in study area;
- rarity in study area; and
- stressors and threats in study area.

The benefits of the conservation strategy for each of the covered species are summarized in **Table ES-2**.

## Reserve System

The heart of the conservation strategy is the creation of a Reserve System that will protect an estimated 46,920 acres for the benefit of covered species, natural communities, biological diversity, and ecosystem function. Land acquisition and protection will create a network of reserves that accomplishes the following:

- Acquires and permanently protects a minimum of 33,205 acres and an estimated 33,629 acres of land for the benefit of covered species, natural communities, biological diversity, and ecosystem function.
- Permanently protects up to 13,291 acres of existing open space areas and enhances the long-term management and monitoring on those lands within the Reserve System. Therefore, the total size of the Reserve System will be an estimated 46,496 acres to 46,920 acres.
- Protects 100 miles of streams.
- Provides management and monitoring of habitats on protected lands to enhance populations of covered species and maintain ecosystem processes.
- Preserves major local and regional connections between key habitat areas and between existing protected areas.

The Plan describes a detailed but flexible process to assemble the Reserve System using acquisition of fee title or conservation easements from willing sellers and partnerships with other conservation organizations already active in the region. Reserve assembly will be required to stay ahead of the impacts of covered activities. All land acquisition will be completed by Year 45 of the permit term.

## Habitat Enhancement and Restoration

All terrestrial and aquatic land cover types in the Reserve System, including streams, will be enhanced to benefit covered and other native species. Wetland and aquatic land cover types will be restored, which involves the recovery of a natural community that has been ecologically degraded. Restoration actions will promote ecosystem recovery by enhancing functional processes, species composition, and community structure. To contribute to species recovery, a minimum of 90 acres of riparian woodland and scrub, wetlands, and ponds will be restored and a minimum of 1.0 mile of stream will be restored regardless of

the level of impacts. The remaining restoration will occur according to ratios of 1:1 or 2:1. If all predicted impacts occur, the Plan will restore up to 500 acres of riparian woodland and scrub, wetlands, and ponds, and up to 10.4 miles of streams to offset losses of these land cover types and to contribute to species recovery. Construction of all habitat-restoration or creation projects will be completed by Year 40 of the permit term.

## Adaptive Management and Monitoring

Adaptive management is a decision-making process promoting flexible management such that actions can be adjusted as uncertainties become better understood or as conditions change. Monitoring the outcomes of management is the foundation of an adaptive approach. The Plan contains detailed guidelines and recommendations for monitoring landscapes as well as the management, enhancement, or restoration of the following land cover types:

- Grassland, including serpentine grassland,
- Chaparral and northern coastal scrub,
- Oak and conifer woodland,
- Riverine and riparian forest, and
- Wetlands and ponds.

The Plan also contains guidelines for the monitoring and adaptive management of each covered species. The program will incorporate important principles of “learning by doing” into the operation of the Reserve System.

## Conditions on Covered Activities

A primary component of regional species protection is the development of comprehensive avoidance and minimization measures to help ensure that impacts from covered activities are reduced. As such, the Plan has developed broad principles for regional avoidance and minimization as well as specific conditions on covered activities. All Permittees and private applicants under the jurisdiction of Gilroy, Morgan Hill, San José, and the County will be required to adhere to these measures in order to receive take authorization. All parties covered by the Plan will submit an application package to receive or document take authorization.

As a regional conservation plan, one of the greatest benefits of the Plan is that mitigation for individual projects can be implemented systematically on a landscape scale. Regional avoidance and minimization concentrates protection in areas where it has the greatest value. By protecting high-quality areas and restricting covered activities in these areas, regional avoidance and minimization goals are supported. Conditions on covered activities are included that

- minimize impacts on sensitive natural communities and covered species,

- minimize impacts on select ground-dwelling wildlife species during project construction,
- ensure compliance with related state and federal wildlife laws,
- establish a comprehensive stream- and riparian-setback requirement, and
- protect water quality in wetlands and streams.

## Implementation

A new organization will be created to oversee assembly and operation of the Reserve System, oversee implementation of other conservation actions, develop and oversee the management and monitoring program, and ensure compliance with all terms of the Plan, permits, and Implementing Agreement. This *Implementing Entity* will be run by a Governing Board and Implementation Board that will consist of designated officials from each of the Permittees. The Implementing Entity will be advised by representatives of USFWS and CDFG, local land-management agencies, a technical advisory committee, a pool of science advisors, and a public advisory committee. It is anticipated that the Implementing Entity will partner with existing agencies and organizations to conduct a significant portion of its responsibilities.

The Plan also includes a detailed process for land acquisition from willing sellers and allowances for landowners to provide land in lieu of fees under certain circumstances.

## Cost and Funding

The cost of implementing the HCP/NCCP during the 50-year permit term is estimated at an average of approximately \$11 million annually. This includes the cost of land acquisition, Plan administration, habitat management, habitat restoration, biological monitoring, remedial measures, and a contingency. Plan costs were estimated from a detailed model of all expected cost components based on actual costs of tasks.

In addition, the Plan will create an endowment during the permit term to fund all needed implementation after the permit term. An endowment of \$90 million in current dollars is needed to generate average annual real returns of \$3.5 million to fund post-permit term management and monitoring of the Reserve System.

Plan funding will come from a number of different sources, including fees on private development and public infrastructure, conservation actions by local and state agencies, and state and federal funding. In general, non-fee funding from local, state, and federal sources will contribute to the conservation needs of the Plan (i.e., the contribution to species recovery). Additional information on funding sources is provided below:

- **Development Fees (Private).** This source includes developer mitigation fees or developer land dedications in lieu of fees.
- **Development Fees (Public Infrastructure).** This source includes fees paid by public infrastructure projects and operations that are covered by this Plan such as roads, flood-control and water-supply facilities, and other public projects.
- **Local Funding.** Non-fee local funding will take many forms, including continued and new investments in conservation actions and land acquisition by organizations such as the Santa Clara County Parks and Recreation Department (County Parks), local land management agencies, local land trusts, and local foundations.
- **State and Federal Funding.** This source includes federal and state grant programs that may fund land acquisition, habitat restoration, and other conservation actions. Some of these funding sources are generally available throughout the state and nation, while others can only be used to implement an approved HCP or NCCP.

A summary of the Plan costs and funding strategy is presented in **Table ES-3**.

The Plan establishes a framework for compliance with state and federal endangered-species laws and regulations that accommodates future growth in the study area. Without the Plan, public and private entities whose activities would affect listed species and their habitats would be required to obtain permits and approvals from USFWS and CDFG before undertaking those activities to mitigate the impacts of their activities on the listed species. Project proponents may also have to implement mitigation required by local jurisdictions based on an environmental analysis conducted for CEQA compliance. To comply with the NCCP Act, the Habitat Plan also provides for contribution to the recovery (“conservation”) of the covered species. Proponents of private and public development activities will benefit from this comprehensive approach in several ways: they will be assured of take coverage; they will avoid the time and expense of securing their own regulatory approvals; and they will have certainty and predictability with respect to their permit obligations. Consequently, the mitigation fees imposed to implement the Habitat Plan include some of the costs associated with the conservation activities. However, because a variety of groups will directly benefit from the Habitat Plan, those groups will also share in the responsibility for funding and otherwise implementing the Habitat Plan.

**Table ES-3. Habitat Plan Cost and Funding Overview**

Type	Amount (rounded to nearest \$10,000)
<b>Estimated Costs Over Permit Term</b>	
Land Acquisition	\$278,940,000
Reserve Management and Maintenance	\$95,360,000
Monitoring, Research, and Scientific Review	\$30,230,000
Western Burrowing Owl Conservation Strategy	\$8,570,000
Habitat Restoration/Creation	\$92,630,000
Program Administration	\$45,890,000
Contingency Fund	\$12,420,000
Plan Preparation Costs	\$3,010,000
Endowment Balance at End of Permit Term	\$90,140,000
<b>Total Estimated Costs</b>	<b>\$657,190,000</b>
<b>Projected Funding<sup>1</sup></b>	
<u>Fee Funding</u>	
Land Cover and Nitrogen Deposition Fees	\$175,460,000
Serpentine Fee	\$29,270,000
Wetland Fee	\$77,600,000
Burrowing Owl Fee	\$8,830,000
Temporary Impact Fees	\$16,010,000
Endowment Fee Component	\$36,500,000
Plan Preparation Fee Component	\$3,010,000
Participating Special Entity Fees	\$17,000,000
Total projected fee funding	\$363,680,000
<u>Non-Fee Funding</u>	
Land acquisition by County Parks	\$45,980,000
Land acquisition by other local land agencies, non-profits, foundations	\$77,270,000
Interest Income on Permit Period Funding	\$2,180,000
Endowment Investment Income	\$53,640,000
New Wildlife Agency funds (ESA Section 6, park bonds, etc.)	\$115,000,000
Total Non-Fee Funding	\$294,070,000
<b>Total Projected Funding</b>	<b>\$657,750,000</b>

**Table ES-2.** Summary Evaluation of Species Proposed for Coverage by the Santa Clara Valley Habitat Plan

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Bay checkerspot butterfly (<i>Euphydryas editha bayensis</i>)/(T/–)</b>			
<b>Status in Range:</b> Most historic populations occurring in the southern and eastern portions of the greater San Francisco Bay Area in serpentine grassland habitat have been extirpated, with the exception of south-central Santa Clara County (multiple locations) and one reintroduction site in San Mateo County. The reintroduction had very limited success, one adult was observed in 2008, the year following the reintroduction. Species is reported to be declining within its highly restricted range.	<b>Land Acquisition:</b> 3,800 acres modeled habitat acquired for Reserve System. 754 acres modeled habitat added to Reserve System from existing open space. Successful implementation of the Habitat Plan will result in the acquisition, protection, and management of a portion of most Bay checkerspot critical habitat units, all four of the core habitat areas as identified in Figure 5-A of the 1998 Serpentine Recovery Plan (Kirby, Metcalf, San Felipe, and Silver Creek Hills) to ensure occupancy of each of the four core habitat units, and at least three of the six (50%) satellite habitat units identified in the 1998 Serpentine Recovery Plan (W. Hills of Santa Clara Valley, Tulare Hill, Santa Teresa Hills, Calero, Communication Hill, or North of Llagas Avenue) by Year 45. Protection of sites will be prioritized according to threat, patch size, current occupancy, and prevalence of cool microsites.	<b>Permanent:</b> 300 acres of modeled primary habitat (3%), which includes a maximum of 300 acres of critical habitat.	Conduct annual surveys of post-diapause larvae in occupied habitat and of host plants and adult butterflies in suitable, unoccupied habitat. Evaluate species response to grassland management. Evaluate translocation efforts determine success of new population establishment.
<b>Status in Permit Area:</b> 8,621 acres of modeled habitat. 1,336 acres of modeled habitat currently protected in Type 1 open space. Species is abundant in multiple populations along the eastern foothills, from Silver Creek Hills down Coyote Ridge to Pigeon Point. Several populations regularly comprise more than 250,000 adult butterflies. South of Pigeon Point, species is present in small patches of grassland west of Coyote Reservoir. On west side of permit area, species is variably present in serpentine grasslands adjacent to Hale Avenue, adjacent to Kalana Avenue, in southern portions of the Santa Teresa Hills, in hills near Calero Reservoir, and on Tulare Hill. Species is reported to be declining in the permit area.	<b>Enhancement, Restoration, and Creation:</b> All acquired/added habitat enhanced to ensure occupancy of at least three of the six (50%) satellite habitat units identified in the 1998 Serpentine Recovery Plan (W. Hills of Santa Clara Valley, Tulare Hill, Santa Teresa Hills, Calero, Communication Hill , or North of Llagas Avenue). Conservation strategy specifies appropriate grazing regimes, prescribed burns, seeding with native forbs and grasses, and other appropriate vegetative management techniques to increase diversity of native plants on acquired species habitat. Translocation of species from core populations to unoccupied suitable habitat may be conducted in close coordination with the Wildlife Agencies.	<b>Temporary:</b> 54 acres of modeled primary habitat (<1%), which includes a maximum of 49 acres of critical habitat.	
<b>Conditions on Covered Activities:</b> Development guidelines will ensure that impacts on this species from covered activities are minimized (Condition 13). This includes design measures to limit project footprint, buffer establishment, and landscaping restrictions. Surveys will be conducted to evaluate habitat quality and allow for development to occur as far as possible from high-quality habitat.			
<b>Net effects:</b> Up to 354 acres (4%) of modeled primary habitat, including 349 acres of critical habitat, will be affected by covered activities. The Reserve System will protect a minimum of 4,554 acres of modeled primary habitat as Type 1 open space all of which will be enhanced. This will result in a 341% increase of lands managed as primary habitat and a total of 68% of existing modeled habitat protected as Type 1 open space. Extensive land acquisition will protect all four of the core habitat areas as defined in the recovery plan for the species namely, Kirby, Metcalf, San Felipe, and Silver Creek Hills and secondary sites deemed essential for species recovery. Most critical habitat units will be partially protected with the successful implementation of the Habitat Plan (including lands currently protected as Type 1 open space). New reserves will ensure protection of the ranges of slopes, aspects, and microhabitats important to the species (LAND-G3, L5) and management of habitat to enhance populations of larval host plants and adult nectar sources to allow for natural migration across reserves (GRASS-1–4, LM-11). Targeted studies will allow for population translocation to unoccupied suitable habitat (GRASS-7) with close coordination with the Wildlife Agencies. Development guidelines will ensure that indirect impacts on this species from covered activities that occur outside the Reserve System are minimized. This includes limiting impacts to 3%, 11%, or 13% in any one core area (Condition 13). The Plan will contribute substantially to the recovery of the species in the permit area and, consequently, throughout its range through habitat acquisition, habitat enhancement, and avoidance or minimization of direct impacts on the species.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>California tiger salamander (<i>Ambystoma californiense</i>)/(T/T)</b>			
<b>Status in Range:</b> Endemic to grasslands of California, species is distributed in six populations: (1) Santa Rosa, Sonoma County; (2) Bay Area (central and southern Alameda, Santa Clara, western Stanislaus, western Merced, and San Benito Counties); (3) Central Valley (Yolo, Sacramento, Solano, eastern Contra Costa, northeast Alameda, San Joaquin, Stanislaus, Merced, and northwestern Madera Counties); (4) southern San Joaquin Valley (portions of Madera, central Fresno, and northern Tulare and Kings Counties); (5) Central Coast Range (southern Santa Cruz, Monterey, northern San Luis Obispo, and portions of western San Benito, Fresno, and Kern Counties); and (6) Santa Barbara County. Most populations occur at elevations of 200–1,500 feet, having been extirpated at lower elevations due to presence nonnative species in breeding ponds; however, extirpation has occurred across species range due to habitat loss. Species is reported to be declining throughout its limited California range.	<b>Land Acquisition:</b> 30,150 acres modeled habitat acquired for Reserve System. 11,745 acres modeled habitat added to Reserve System from existing open space.  Included in the acreages above are 50 to 104 acres of ponds and 15 to 80 acres of wetlands. Reserve System species occupancy requirements include 25% of ponds/wetlands by Year 30 and 30% by Year 45. Extensive land acquisition will occur in 7 critical habitat units. Target areas include areas adjacent to existing open space (Joseph D. Grant County Park, Palassou Ridge Open Space Preserve, and Henry W. Coe State Park), and isolated areas (east of Uvas Reservoir) with known species occurrences. To ensure habitat connectivity, upland habitat between ponds/wetlands will be targeted between known occurrences in Santa Cruz foothills and Diablo Range, including areas near Santa Teresa Hills and Tulare Hill, and along Pajaro River south of Gilroy.	<b>Permanent:</b> 77 acres of modeled breeding habitat (7%). 12,855 acres of modeled non-breeding habitat (4%). 12,932 acres total, (4%), including up to 264 acres of critical habitat.	Conduct annual surveys of occupied and potential breeding and upland habitat. Evaluate species response to habitat enhancement, restoration, or creation. Determine species response to predator control programs. Determine effects of and response to additional threats, such as diseases and hybridization.
<b>Status in Permit Area:</b> 324,748 acres of modeled habitat (breeding and non-breeding). 45,767 acres of modeled habitat currently protected in Type 1 open space (breeding and non-breeding). Approximately 100 occurrence records (1990–2005) scattered throughout the permit area and on both sides of the Santa Clara valley, with large clusters of occurrences in Joseph D. Grant County Park. Eight historical breeding areas along the valley floor and along the US 101 corridor have been extirpated due to habitat conversion to development. Status of species in permit area is unknown.	<b>Enhancement, Restoration, and Creation:</b> 50 to 104 acres of ponds and 15 to 80 acres of wetlands enhanced. 20 to 72 acres of ponds created/ 20 to 75 acres of wetlands restored. Conservation Strategy specifies targeting sites to reduce habitat fragmentation and promote genetic exchange within the population. This includes sites within dispersal distance of known breeding sites to contribute to species recovery, as well as replacement of sites lost to covered activities. Site characteristics include hydrologic, geomorphic, and soil conditions to ensure successful restoration/creation. All acquired/added habitat will be enhanced to ensure occupancy of 30% of ponds and wetlands in each of the federal Recovery Units 4 and 6 in the Reserve System.	<b>Temporary:</b> 14 acres of modeled breeding habitat (1%). 1,529 acres of modeled non-breeding habitat (<1%). 1,543 acres total (<1%), including up to 119 acres of critical habitat.	
<b>Conditions on Covered Activities:</b> Development guidelines for wetlands and ponds (breeding habitat) and valley oak and blue oak woodlands (upland habitat) will minimize effects of covered activities (Conditions 12, 14). Stream and Riparian Setbacks, may also have ancillary benefits to this species. Although the streams themselves do not provide habitat, aquatic breeding sites and dispersal corridors may be located within the riparian areas protected by the setbacks (Condition 11). Project planning guidelines include maintenance of landscape connectivity, maintenance of site hydrology to the extent possible, and establishment of buffer/setback requirements. Construction guidelines include buffer zone establishment and fencing; staking of wetlands/ponds during construction; staff training by professional biologist; erosion control measures; and restrictions on seasonality of activities, vegetative management, use of heavy machinery, access points, and ground disturbance (Conditions 12, 14). Recreational use guidelines include leash law restrictions and public access limitations within reserve recreational use areas to prevent potential species impacts from domestic dogs (Condition 9).			
<b>Net effects:</b> Up to 91 acres (9%) of modeled breeding habitat and 14,384 acres (4%) of modeled non-breeding habitat, including 383 acres of critical habitat, will be affected by covered activities. The Reserve System will protect and enhance a minimum of 195 acres of modeled breeding habitat and 41,700 acres of non-breeding habitat as Type 1 open space. This will result in an increase of 92% of lands managed as species habitat and a total of 27% of modeled habitat protected as Type 1 open space. A minimum of 105 and up to 331 acres of aquatic habitat will be created/restored/enhanced in the Reserve System. Some of these sites will be suitable species habitat. A network of core reserves will protect large blocks of breeding/non-breeding habitat. New linkages will be created in blocks of modeled habitat to facilitate dispersal and colonization throughout the permit area and movement between breeding sites (LAND-G2, OC1–5, WP4–7). Habitat management will improve quality of breeding habitat (e.g., predator eradication and access control programs, woody debris and native vegetation installation) and upland habitat (e.g., grassland management) (POND-1–4, 9–11, 13; GRASS-1, 2; LM-11–14; STUDIES-7, 8). Development guidelines will ensure that impacts on this species from covered activities outside the Reserve System are minimized (Conditions 9, 12, 14). The Plan is likely to benefit the species in the permit area through habitat acquisition, habitat enhancement/restoration, and avoidance and minimization of direct impacts on the species.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>California red-legged frog (<i>Rana aurora draytonii</i>)/(T/CSC)</b>			
<b>Status in Range:</b> Although the historical distribution extended south along the coast from Pt. Reyes National Seashore in Marin County and inland from Redding in Shasta County to northwestern Baja California, current distribution is limited to isolated patches in the Sierra Nevada, Northern Coast Ranges, and Santa Monica Mountains. Taxon remains common in the San Francisco Bay area and along the central coast. In southern California, taxon is believed extirpated from Santa Rosa Ecological Reserve but persists in the Santa Monica Mountains and in San Fransquito Canyon in Newhall. Species is reported to be declining at a global scale, as well as in California.	<b>Land Acquisition:</b> 31,300 acres modeled habitat acquired for Reserve System. 11,930 acres modeled habitat added to Reserve System from existing open space. Included in the acreages above are 15 to 80 acres of wetlands, 50 to 104 acres of ponds, and 100 miles of streams. 35% of ponds/wetlands in each of the federal Recovery Units 4 and 6 in the Reserve System will be occupied by species by Year 30 and with 40% by Year 45. Target areas include the East San Francisco Bay Recovery Unit, Critical Habitat Unit STC-1A, and areas adjacent to existing open space with known species occurrences, such as Joseph D. Grant County Park, Palassou Ridge Open Space Preserve, and Henry W. Coe State Park.	<b>Permanent:</b> 299 acres of modeled primary habitat (3%). 12,937 acres of modeled secondary habitat (4%). 13,236 acres total (4%), including 1,023 acres of critical habitat.	Conduct preacquisition baseline surveys to document species occupancy, potential occupied breeding habitat, quality of upland habitat around occupied or potential breeding habitat, presence of predators, and presence of other threats that may affect reproductive success. Determine presence/absence of potential breeding adults through nighttime breeding season surveys. Conduct daytime surveys to determine local species population. Determine species response in occupied habitat to enhancement and restoration techniques. Evaluate quality and quantity of adjacent uplands using ground squirrel colony size and burrow density as a proxy. Determine species response to predator control programs. Monitor disease to prevent population epidemic.
<b>Status in Permit Area:</b> 341,773 acres of modeled habitat (primary and secondary). 46,253 acres of modeled habitat currently protected in Type 1 open space. Species has been extirpated from the urbanized valley floor and brackish marshlands bordering the San Francisco Bay due to habitat removal/degradation and invasive species predation. Species persists in the foothills and mountain ranges throughout the county. There are 93 documented occurrences, with adult frogs observed in creeks from Upper Alameda Creek (Sunol Regional Wilderness) south to Henry W. Coe State Park, with half the occurrences in Henry W. Coe State Park, 24 on private property, and the remainder on public properties of City of San José, Santa Clara Valley Water District, and Santa Clara County. Species is reported to be declining in the permit area.	<b>Enhancement, Restoration and Creation:</b> All acquired/added habitat enhanced to ensure occupancy of 25% of ponds and wetlands in the entire Reserve System. 10 to 50 acres of wetlands/ 50 to 104 acres of ponds enhanced. 20 to 45 acres of perennial wetlands restored. 20 to 72 acres of ponds created. Conservation Strategy specifies increasing habitat, enhancing connectivity among existing ponds and wetlands, and contributing to species recovery. Sites will be targeted to reduce habitat fragmentation and promote genetic exchange within the population, and will include hydrologic, geomorphic, and soil conditions to ensure successful restoration/creation.	<b>Temporary:</b> 116 acres of modeled primary habitat (1%). 1,489 acres of modeled secondary habitat (<1%). 1,605 acres total (<1%), including 276 acres of critical habitat.	
<b>Conditions on Covered Activities:</b> Development guidelines for wetlands, ponds, and streams (breeding habitat) and valley oak and blue oak woodlands (upland habitat) will ensure that impacts from covered activities are minimized (Conditions 4, 5, 11, 12, 14). Project planning guidelines include maintenance of landscape connectivity, maintenance of site hydrology to the extent possible, and establishment of buffer/setback requirements. Construction guidelines include buffer zone establishment and fencing; staking of wetlands/ponds during construction; staff training by professional biologist; erosion control measures; and restrictions on seasonality of activities, vegetative management, use of heavy machinery, access points, and ground disturbance. Recreational use guidelines include leash law restrictions and public access limitations within reserve recreational use areas to prevent potential species impacts from domestic dogs (Condition 9).			
<b>Net effects:</b> Up to 415 acres (4%) of modeled primary habitat and 14,426 acres (4%) of modeled secondary habitat will be affected by covered activities. The Reserve System will protect and enhance a minimum of 1,430 acres of modeled primary habitat and 41,800 acres of modeled secondary habitat. This will result in an increase of 93% of protected modeled habitat and a total of 26% of modeled habitat protected as Type 1 open space. A minimum of 100 and up to 271 acres of aquatic habitat will be created/restored/enhanced. Some of these sites will be suitable species habitat. A network of core reserves will protect large blocks of breeding/non-breeding habitat. New linkages will be created in blocks of modeled habitat to facilitate dispersal and colonization throughout the permit area and movement between breeding sites (LAND-G2, OC1–5, WP4–7). Habitat management will improve quality of breeding habitat (e.g., predator eradication and access control programs, woody debris and native vegetation installation) and upland habitat (e.g., grassland management) (POND-1–4, 10, 11, 13; GRASS-1, 2; LM-10–13; STUDIES-7, 8). Development guidelines will ensure that impacts from covered activities outside the Reserve System are minimized (Conditions 3, 4, 5, 9, 11, 12, 14). The Plan is likely to benefit the species in the permit area through habitat acquisition, habitat enhancement/restoration, and avoidance and minimization of direct impacts on the species.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Foothill yellow-legged frog (<i>Rana boylei</i>)/(-/CSC)</b>			
<p><b>Status in Range:</b> Species range extends from west of the crest of the Cascade mountains in Oregon south to the Transverse Ranges in Los Angeles County, and in the Sierra Nevada foothills south to Kern County, excluding coastal areas south of northern San Luis Obispo County and foothills area south of Fresno County, where the species is apparently extirpated. Known elevation range extends from near sea level to ~6,700 feet. Species is still common along the northern California coast as well as in suitable habitat in the Diablo Range in Alameda, western Stanislaus, Santa Clara, San Benito, and western Fresno Counties. Species is reported to be declining at a global scale, as well as within California.</p>	<p><b>Land Acquisition:</b> 80 stream miles of modeled habitat acquired for Reserve System. 24 stream miles of modeled habitat added to Reserve System from existing open space. Protect occupied habitat in the Reserve System in at least four of the watersheds in Figure 3-6. Occupied habitat within the Reserve System is defined as perennial streams with an observation of egg masses by Year 45. Occupancy will be demonstrated upstream of dams that present permanent barriers to the species or on streams unaffected by dam operations and must be in both the Diablo Range and in the Santa Cruz Mountains. Target areas include streams that have, or historically had, perennial flows and cobblestone substrate.</p>	<p><b>Permanent:</b> 1.9 stream miles of modeled primary habitat (1%). 4.8 stream miles of modeled secondary habitat (4%). 6.7 stream miles total (1%).</p>	<p>Assess habitat quality and conduct visual detection baseline surveys (to determine species presence/absence) in potential species habitat prior to Reserve System land acquisition. Document species baseline levels using in-depth population surveys, as warranted. Determine changes in number of egg masses (i.e., weekly egg mass surveys during peak egg-laying period) to evaluate species response to enhancement and restoration of stream habitat and riparian corridors (e.g., addition of cobblestone substrate, riparian plantings, livestock exclusion). Conduct a directed study to inform how and when reservoir releases should be implemented during egg-laying months. Determine species response to predator control programs. Monitor disease to prevent population epidemic. Evaluate species response to barrier removal.</p>
<p><b>Status in Permit Area:</b> 690 stream miles of modeled habitat. 119 miles of modeled habitat currently protected in Type 1 open space (primary and secondary habitat). Species has been virtually extirpated from the lowland areas and from many of the perennial streams below major reservoirs; however, species remains abundant in the foothills and mountains of eastern Santa Clara County. Species is still found in the upper reaches of most perennial streams, including Coyote Creek and nearly all the streams of the Pajaro watershed. Species is reported to be declining within the permit area.</p>	<p><b>Enhancement, Restoration, and Creation:</b> All stream miles of acquired/added habitat enhanced to ensure occupancy in at least three of the watersheds in the Reserve System. 1 to 10.4 stream miles restored. Conservation Strategy specifies targeting reaches of perennial streams above the Uvas, Calero, Chesbro, Anderson, or Coyote Reservoirs, Uvas Creek below Uvas Reservoir, Little Arthur Creek, Upper Penitencia Creek, Alamitos Creek, and Guadalupe Creek. Riparian vegetation will be seeded/planted to create structural diversity, provide overhead cover, and regulate stream temperature. Cobblestone substrate will be increased in _ stream miles within model habitat to increase breeding habitat suitability. Uvas Reservoir releases will be adjusted to create necessary seasonal flow regimes. Herbicide and other vegetative treatments will be selectively applied to avoid species impacts.</p>	<p><b>Temporary:</b> 0.7 stream miles of modeled primary habitat (&lt;1%). 1.3 stream miles of modeled secondary habitat (&lt;1%). 2.0 stream miles total (&lt;1%).</p>	
<p><b>Conditions on Covered Activities:</b> Development and operations and maintenance guidelines will ensure that impacts from covered activities are avoided or minimized through maintenance of hydrologic conditions and protection of water quality (Condition 3), stream avoidance and minimization for in-stream projects (Condition 4), BMPs for in-stream operations and maintenance (Condition 5), rural development design requirements (Condition 7), preparation and implementation of a Reserve System recreation plan (Condition 9), and riparian setbacks (Condition 11). Conditions include but are not limited to: creation of landscape features to maintain preproject hydrograph, remove pollutants and sediments from surface runoff prior to stream entry, and reduce runoff velocity; development of construction sediment and erosion management plans; installation of fish passage mechanisms during in-stream work; and bank stabilization. Recreational use guidelines include leash law restrictions and public access limitations within reserve recreational use areas to prevent potential species impacts from domestic dogs (Condition 9).</p>			
<p><b>Net effects:</b> Up to 8.7 stream miles (&lt;1%) of modeled habitat will be affected by covered activities. The Reserve System will protect and enhance a minimum of 37 stream miles of modeled primary habitat and 67 stream miles of modeled secondary habitat. This will result in an 88% increase of protected modeled habitat as Type 1 open space and protection of a total of 32% of modeled habitat protected as Type 1 open space. Within the Reserve System a minimum of 1 and up to 10.4 stream miles will be restored. Some of these sites will be suitable species habitat. Engineered channels will be replaced to restore floodplain connectivity (STREAM-4, 5). Protection of streams with perennial flows will target reaches with high habitat value or restoration potential (LAND-R5). Restoration and enhancement of perennial streams (e.g., selective herbicide applications, riparian plantings, increase in cobblestone substrate, appropriate flow regimes) will ensure improvement of habitat quality and breeding success (LM-14; STREAM-2, 4, 5, 8; STUDIES-6). Development guidelines will ensure that impacts from covered activities outside the Reserve System are minimized (Conditions 3,-5, 7, 9, 11). The Plan is likely to benefit the species in the permit area through habitat acquisition, habitat enhancement/restoration, and avoidance and minimization of direct impacts on the species.</p>			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Western pond turtle (<i>Clemmys marmorata</i>)/(-/CSC)</b>			
<b>Status in Range:</b> Species range extends from most Pacific slope drainages from Klickitat County, Washington, along the Columbia River, to Arroyo Santa Domingo in northern Baja California. In California, it was historically present in most Pacific slope drainages between the Oregon and Mexican borders. Occurring in 90% of its historic California range in the Central Valley and west of the Sierra Nevada, its numbers have been greatly reduced. Species is reported to be declining at a global scale; however, the species status in California is unknown due to lack of data.	<b>Land Acquisition:</b> 27,000 acres modeled habitat acquired for Reserve System. 11,900 acres modeled habitat added to Reserve System from existing open space. Included in the acreages above are 50 to 104 acres of ponds, 10 to 50 acres of perennial wetlands, and 100 stream miles. 20% of ponds and wetlands in the entire Reserve System will be occupied by western pond turtles by Year 30. 25% of ponds and wetlands in the entire Reserve System will be occupied by western pond turtles by Year 45. Target areas include stream segments or ponds that currently provide or could provide high-quality basking, breeding, and nesting habitat. This includes land between existing ponds and wetlands that provide a linked matrix of pond, wetland, and upland habitat.	<b>Permanent:</b> 1,824 acres of modeled primary habitat (2%). 7,825 acres of modeled secondary habitat (3%). 9,649 acres total (3%).	Assess habitat quality and document baseline population levels in potential habitat within Reserve System acquisitions. Determine population response (i.e., changes in the average number of individuals basking) to enhancement and restoration of occupied habitat. Assess effects of habitat management (e.g., livestock exclusion) on nesting and basking habitat and determine population response.
<b>Status in Permit Area:</b> 314,916 acres of modeled habitat. 44,967 acres of modeled habitat currently protected in Type 1 open space (primary and secondary habitat). Species occurs throughout the Coyote Creek drainage from its upper reaches in Henry W. Coe State Park to the urbanized reaches in San José; however, the majority of known occurrences are in the southern half of the county, namely Uvas and Llagas Creeks where they enter reservoirs. Species status is unknown in the permit area due to lack of targeted studies; reported occurrences are thought to be biased by incidental observation, consequently, occurrences may be more extensive throughout the permit area.	<b>Enhancement, Restoration, and Creation:</b> All acquired/added habitat enhanced to ensure occupancy of 25% of ponds and wetlands in the entire Reserve System. 50 to 104 acres of ponds enhanced. 20 to 72 acres of ponds created. 20 to 45 acres of perennial wetlands restored. 1 to 10.4 stream miles restored. Habitat management of riverine and riparian forest and scrub, wetlands, and ponds will increase the quality and quantity of species habitat within the permit area. Artificial basking substrate and woody debris will be installed to create suitable basking sites.	<b>Temporary:</b> 440 acres of modeled primary habitat (<1%). 986 acres of modeled secondary habitat (<1%). 1,426 acres total (<1%).	
<b>Conditions on Covered Activities:</b> Development guidelines for wetlands, ponds, and streams and valley oak and blue oak woodlands will ensure that impacts from covered activities are avoided and minimized (Conditions 4, 5, 11, 12 & 14). Project planning guidelines include maintenance of landscape connectivity, maintenance of site hydrology to the extent possible, and establishment of buffer/setback requirements. Construction guidelines include buffer zone establishment and fencing; staking of wetlands/ponds during construction; staff training by professional biologist; erosion control measures; and restrictions on seasonality of activities, vegetative management, use of heavy machinery, access points, and ground disturbance. Recreational use guidelines include leash law restrictions and public access limitations within reserve recreational use areas to prevent potential species impacts from domestic dogs (Condition 9).			
<b>Net effects:</b> Up to 2,264 acres (3%) of modeled primary habitat and 8,811 acres (4%) of secondary habitat will be affected by covered activities. The Reserve System will protect a minimum of 9,800 acres of modeled primary habitat and 29,100 acres of modeled secondary habitat. All habitat within Reserve System will be enhanced. This will result in an 87% increase of lands managed as species habitat and protection of a total of 27% of modeled habitat protected as Type 1 open space. Within the Reserve System 100 stream miles, a minimum of 50 and up to 104 acres of ponds, and a minimum of 10 and up to 50 acres of perennial wetlands will be protected. A minimum of 20 and up to 72 ponds will be created. A minimum of 20 and up to 45 acres of perennial wetlands and minimum of 1 and up to 10.4 stream miles will be restored. A portion of these stream and aquatic natural community acquisition, creation, and restoration sites will provide suitable species habitat. A network of core reserves will protect large blocks of breeding/non-breeding habitat. New linkages will be created in blocks of modeled habitat to facilitate dispersal and colonization throughout the permit area and movement between breeding sites (LAND-G2, OC1–5, WP4–7). Habitat management will improve quality of breeding habitat (e.g., predator eradication and access control programs, woody debris and native vegetation installation) and upland habitat (e.g., grassland management) (STREAM-1–3; LM-11–14; POND-1–4, 9–11, 13; GRASS-1, 2; STUDIES-7–9). Development guidelines will ensure that impacts from covered activities outside the Reserve System are minimized (Condition 9, 12, 14). The Plan is likely to benefit the species in the permit area through habitat acquisition, habitat enhancement/restoration, and avoidance and minimization of direct impacts on the species.			

Table ES-2. Continued

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Western burrowing owl (<i>Athene cunicularia hypugea</i>)/(MBTA/CSC)</b>			
<p><b>Status in Range:</b> Species is found throughout western North American, west of the Mississippi River and south into Mexico. In California, species range extends through the lowlands south and west from north central California to Mexico, with small, scattered populations occurring in the Great Basin and the desert regions of the southwestern part of the state. Species is absent from the coast north of Sonoma County and from high mountain areas. Populations have been greatly reduced or extirpated from most of the San Francisco Bay Area and along the California coast to Los Angeles. The remaining major population densities are in the Central and Imperial Valleys. Species is reported to be declining at a global scale, as well as within California.</p>	<p><b>Land Acquisition, Easement, or Management Agreement:</b>  <u>Overwintering Habitat</u>  17,000 acres modeled overwintering habitat acquired for Reserve System.  4,310 acres modeled overwintering habitat added to Reserve System from existing open space.  <u>Nesting Habitat</u>  5,300 acres occupied and potential nesting habitat managed with permanent long-term management plans by Year 45. A minimum of 600 of these 5,300 acres will be occupied nesting habitat acquired in fee title or easement for the Reserve System.  The geographic breakdown of nesting habitat would include the following minimums: 3,700 acres in the North San José/Baylands region, 800 acres in the Gilroy region, 530 acres in the Morgan Hill region, and 270 acres in the South San José region.</p>	<p><b>Permanent:</b>  9,671 acres of modeled overwintering only habitat (7%).  198 acres of modeled occupied nesting habitat.  4,000 acres of modeled potential nesting habitat.</p>	<p>Assess habitat quality and document available nesting, foraging, and overwintering habitat within the Reserve System. Determine species movements and identify habitat corridors during breeding and wintering seasons. Use multiple approaches (e.g., track nesting pairs, density and distribution of California ground squirrels) to determine species response (i.e., nesting success, site fidelity) to habitat protection and enhancement. Track species response to grassland management by monitoring California ground squirrel colonies to determine burrow and prey availability.</p>
<p><b>Status in Permit Area:</b>  197,869 acres modeled habitat.  13,586 acres of modeled habitat currently protected in Type 1 open space.  There are 25 extant species occurrences in the permit area. Many of these occurrence records include sitings of several breeding individuals over multiple years. Core populations of breeding and overwintering populations of western burrowing owls continue to be at the San José International Airport. Species is reported to be declining within the permit area.</p>	<p><b>Enhancement, Restoration, and Creation:</b>  All acquired/added/managed habitat enhanced.  Conservation Strategy specifies using grassland management to enhance habitat quality through vegetation management, creating artificial burrows and increasing extent of ground squirrel colonies, encouraging the colonization of new areas, and ceasing rodenticide use to the extent possible.</p>	<p><b>Temporary:</b>  762 acres of modeled overwintering habitat (&lt;1%). 20 acres of modeled occupied nesting habitat (&lt;1%).  604 acres of modeled potential nesting habitat (&lt;1%).</p>	
<p><b>Conditions on Covered Activities:</b> Development and operations and maintenance guidelines will ensure that impacts from covered activities are avoided or minimized (Condition 15). Species-specific surveys will be conducted during project planning phase, and potential impacts to occupied breeding habitat will be mapped. Preconstruction surveys will establish species presence/absence. Project monitoring will be coordinated with other regional efforts. Avoidance and minimization measures, including the establishment of a 250-ft buffer zone, will avoid all nest sites that could be disturbed by project construction throughout the breeding season. During the non-breeding season, active burrows will be avoided by the establishment of a 160-ft border, and exclusion doors will be put in place for 48 hours prior to excavation. All project monitoring will be conducted by a qualified biologist.</p>			
<p><b>Net effects:</b> Up to 10,433 acres (8%) of modeled overwintering habitat, 218 acres of estimated occupied nesting habitat, and 4,604 acres of potential nesting habitat will be affected by covered activities. The Reserve System will protect or manage a minimum of 22,300 acres of species habitat (acquire 17,000 acres of modeled overwintering only and 600 acres of occupied nesting habitat, protect or manage another 4,700 acres of occupied or potential nesting habitat) An additional 4,310 acres of modeled overwintering habitat will be incorporated from existing open space. All habitat within the Reserve System or under long-term management will be enhanced. The Implementing Entity will maintain or increase the size of the breeding and overwintering burrowing owl population and increase the distribution of breeding and overwintering burrowing owls in the permit area and the expanded burrowing owl conservation area. New reserves will ensure protection of both breeding and overwintering habitat on the valley floor and in the Diablo Range (LAND G8-10). Habitat management will focus on enhancement of breeding habitat (i.e., vegetation management, artificial burrow creation, limiting rodenticide use, increased ground squirrel colonization) in four regions: North San José/Baylands, Gilroy, Morgan Hill, and South San José (GRASS-5, 6, 8, 9). Development guidelines will ensure that impacts from covered activities that occur outside the Reserve System are minimized (Condition 15). The Plan is likely to benefit the species in the permit area through habitat acquisition, habitat enhancement/restoration, and avoidance and minimization of direct impacts on the species.</p>			

Table ES-2. Continued

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Least Bell's vireo (<i>Vireo bellii pusillus</i>)/(E, MBTA/E)</b>			
<b>Status in Range:</b> A migratory species that breeds in North America and overwinters primarily along the Pacific Coast in southern Mexico. Breeding range extends from north central to southwestern U.S. and into central Mexico. Additional breeding sites have been documented from southwestern California and northwestern Baja California to central South Dakota, east to Illinois and northwestern Indiana, south to the gulf coast and into southern Sonora. Recently, breeding individuals have been reported as far north as southern Santa Clara County along Llagas Creek and in southeastern Monterey, western Merced, and Stanislaus Counties, demonstrating that the species may be expanding back into its historical range. Species is reported to be declining at a global scale, as well as in California; however, there is recent evidence of range extensions in San Joaquin Valley.	<b>Land Acquisition:</b> 460acres modeled habitat acquired for Reserve System. 2 acres modeled habitat added to Reserve System from existing open space. Included in the acreages above are the 290 to 592 acres of riparian forest and scrub and California alluvial sycamore woodland habitat that will be acquired to meet riparian natural community acquisition commitments.  Target areas include riparian woodland habitat in Uvas, Llagas, and Pacheco watersheds.	<b>Permanent:</b> 72 acres of modeled primary habitat (2%).	Survey riparian woodland during the nesting season to document and monitor species status. Evaluate species response to habitat enhancement and restoration. Document nesting success, once a population becomes established in the permit area.
<b>Status in Permit Area:</b> 3,097 acres of modeled habitat. 65 acres of modeled habitat currently protected in Type 1 open space.  Due to isolated, infrequent sighting of the species and lack of survey efforts, the extent of the species range in the permit area is not well understood. Species sightings have occurred along Llagas Creek between SR 152 and the Pajaro River, east of Gilroy (evidence of breeding, nest found) and Coyote Creek near Coyote Creek Golf Club (breeding behavior observed, no nest found). Species is poorly understood in the permit area, but may be increasing.	<b>Enhancement, Restoration, and Creation:</b> All acquired/added habitat enhanced, including 290 to 592 acres of acquired riparian forest/scrub and California alluvial sycamore woodland. Fifty to 353 acres of riparian forest/scrub and California alluvial sycamore woodland will be restored. Target areas include Uvas/Carnadero Creek, Llagas Creek between SR 152 and its confluence with Pajaro River, and sections of Pacheco Creek in Santa Clara County between Pacheco Lake and San Felipe Lake. Geomorphic and ecological stream functions, including floodplain benches, will be restored. All riparian mitigation will occur in Uvas, Llagas, and Pacheco watersheds. Native vegetation will be planted/seeded to promote continuity of riparian corridors and provide mosaic of successional stages. Predator control program, if needed, will be implemented.	<b>Temporary:</b> 43 acres of modeled primary habitat (1%).	
<b>Conditions on Covered Activities:</b> Development guidelines will ensure impacts are avoided and minimized (Condition 16). Surveys will identify and map nesting habitat and active nests for projects occurring in modeled habitat. If nesting habitat is identified, impacts will be avoided and minimized during the breeding season (March 15–July 31). Avoidance measures include relocating impacts at least 250 feet from modeled breeding habitat or conducting work outside of the breeding season. If impacts on least Bell's vireo habitat (occupied or not) are not fully avoided by a 250-foot buffer, preconstruction surveys will be required. Preconstruction surveys will document species presence/absence and habitat use. Occupied nests and previous nesting sites (for up to 3 years) will be avoided during the breeding season (March 15–July 31) with a 250-foot buffer. Required buffers may be reduced on a case-by-case basis as evaluated by the Implementing Entity in coordination with the Wildlife Agencies. If a nest is found, the Wildlife Agencies will be notified immediately. All construction or maintenance personnel must participate in training lead by a qualified biologist.			
<b>Net effects:</b> The Plan does not authorize take of least Bell's vireo in the form of direct injury or mortality. Loss of nests or eggs is also not authorized under the Plan. Up to 115 acres (4%) of modeled primary habitat will be affected by covered activities. The Reserve System will protect a minimum of 462 acres of modeled primary habitat. All species habitat within the Reserve System will be enhanced. This will result in a 711% increase of protected modeled habitat and a total of 17% of modeled habitat protected as Type 1 open space. To meet riparian natural community goals, a minimum of 290, and up 592, acres of riparian forest and scrub will be acquired and enhanced, and a minimum of 50 and up to 353 acres will be restored. Some of these sites may be suitable species habitat. New reserves will increase habitat connectivity by targeting areas along rivers (LAND–R2, R8). Habitat management will ensure improvement of habitat quality and favor increased reproductive success through riparian woodland and forest enhancement/restoration (e.g., predator control program, planting native vegetation) (LM-11; STREAM-2–5, 7). Development guidelines will ensure that impacts on this species from covered activities outside the Reserve System are avoided or minimized (Condition 16). The Plan is likely to benefit the species in the permit area through habitat acquisition, habitat enhancement/restoration, and avoidance and minimization of direct species impacts.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Tricolored blackbird (<i>Agelaius tricolor</i>)/(MBTA/CSC)</b>			
<b>Status in Range:</b> Species is endemic to the west coast of North America, mostly in California. The breeding population is concentrated in the Central Valley with scattered sites occurring in Oregon, Washington, Nevada, and the western coast of Baja California. In California, the historic breeding range included Sacramento and San Joaquin Valleys, lowlands of the Sierra Nevada south to Kern County, the coast region from Sonoma County to the Mexican border, and sporadically on the Modoc Plateau. Species has experienced major declines since 1994. Species is reported to be declining at a global scale, as well as within California.	<b>Land Acquisition:</b> 19,000 acres modeled habitat acquired for Reserve System. 3,840 acres modeled habitat added to Reserve System from existing open space. Included in the acreages above are 50 to 104 acres of ponds and 10 to 50 acres of perennial wetlands. Target areas include suitable breeding habitat in dryland farming or ranching complexes in Coyote Valley and the Diablo Hills, prioritizing currently and recently occupied and historic breeding sites. In addition, foraging habitat will be acquired within 2 miles of known breeding sites.	<b>Permanent:</b> 276 acres of modeled primary habitat (3%). 10,317 acres of modeled secondary habitat (8%). 10,593 acres total (8%).	Assess habitat quality, species occupancy, and colony size of all suitable freshwater wetland or pond habitat in Reserve System. Determine breeding habitat connectivity in permit area. Evaluate species response to habitat enhancement, restoration, or creation. Monitor nesting colony response to nonnative plant removal. Determine need for predator control programs.
<b>Status in Permit Area:</b> 140,291 acres of modeled habitat. 11,037 acres of modeled habitat currently protected in Type 1 open space (primary and secondary habitat). Although consistently present in the permit area, species' distribution in permit area remains sporadic and ephemeral. There are few documented colony occurrences, comprising 150–200 individuals. Because species wanders considerably during the breeding season, individuals could successfully breed in the permit area if suitable breeding and/or foraging habitat were available. Breeding colonies often go unreported because of individuals' similar appearance to that of red-winged blackbird. Data are insufficient to characterize species status in the permit area.	<b>Enhancement, Restoration, and Creation:</b> All acquired/added habitat enhanced. 50 to 104 acres of ponds enhanced. 10 to 50 acres of perennial wetlands enhanced. 20 to 72 acres of ponds created. 20 to 45 acres of perennial wetlands restored. As part of the Conservation Strategy, private landowners will be offered incentives to ensure that farming and ranching practices support foraging habitat. Exclusion fencing will be installed to prevent entry of livestock and feral pigs into breeding habitat. Riparian vegetation will be planted to attract nesting birds. Engineered channels will be replaced where feasible.	<b>Temporary:</b> 93 acres of modeled primary habitat (1%). 768 acres of modeled secondary habitat (<1%). 861 acres total (<1%).	
<b>Conditions on Covered Activities:</b> Development and operations and maintenance guidelines ensure that impacts from covered activities are avoided or minimized (Condition 17). During the project planning phase, a qualified biologist will survey and map potential species nesting habitat. Potential nesting habitat identified by these or any other surveys, will be mapped and direct impacts to potential nesting habitat avoided and other impacts minimized. Avoidance measures include relocating impacts away from the potential nesting habitat. If a project is unable to avoid impacts on species nest colonies by locating construction and staging activities at least 250 feet from the outer edge of all hydric vegetation associated with the colony, preconstruction surveys will be required. Preconstruction surveys will conclude no more than two calendar days prior to construction. Covered activities must avoid species nesting colonies (currently occupied or occupied within the past 5 years) and associated habitat with a 250-ft no-activity buffer zone around the outer edge of all hydric vegetation associated with the colony. Required buffers may be adjusted on a case-by-case basis as evaluated by the Implementing Entity in coordination with the Wildlife Agencies. A construction monitor will be present during breeding season construction when an active colony is present.			
<b>Net effects:</b> No impacts are allowed to active tricolored blackbird colonies. The Plan does not authorize the removal of historic and active breeding sites. Up to 11,454 acres (8%) of modeled habitat will be affected by covered activities. The Reserve System will protect a minimum of 22,840 acres of modeled species habitat. All habitat within Reserve System will be enhanced. This will result in a 207% increase of lands managed as species habitat and a total of 24% of modeled habitat protected as Type 1 open space. A minimum of 50 and up to 104 acres of ponds and a minimum of 10 and up to 50 acres of perennial wetlands will be acquired and enhanced. A minimum of 20 and up to 72 acres of ponds will be created and a minimum of 20 and up to 45 acres of perennial wetlands will be restored. Some of these aquatic natural community acquisition, creation, and restoration sites will provide suitable species habitat. New reserves will ensure protection of at least four currently occupied or historic breeding sites and nearby foraging habitat (LAND WP 8). Land owners will be offered incentives to enhance breeding and foraging habitat on their property (POND-14, 15). Habitat management will focus on restoration and enhancement of ponds, freshwater marshes, and seasonal wetlands (e.g., fencing installation, restoration with native vegetation, replacement of engineered channels) to improve quality of breeding and foraging habitat (POND-1, 6, 8–10, 17, 18; STREAM-4). Development guidelines will ensure that impacts from covered activities that occur outside the Reserve System are minimized (Condition 17). The Plan is likely to benefit the species in the permit area through habitat acquisition, habitat enhancement/restoration, and avoidance and minimization of direct impacts on the species.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>San Joaquin kit fox (<i>Vulpes macrotis mutica</i>)/(E/T)</b>			
<b>Status in Range:</b> Endemic to California, the historic range is estimated to have extended from Contra Costa and San Joaquin Counties in the north to Kern County in the south. Kit foxes currently inhabit some areas of the San Joaquin Valley floor and the surrounding foothills of the Coast Ranges, Sierra Nevada, and Tehachapi Mountains from Kern County north to Contra Costa, Alameda, and San Joaquin Counties. Known occurrences in Alameda, Contra Costa, Fresno, Kern, Kings, Madera, Merced, Monterey, San Benito, San Joaquin, San Luis Obispo, Santa Barbara, Santa Clara, Stanislaus, and Tulare Counties, with the largest extant populations in Kern County and San Luis Obispo County in the Carrizo Plain Area. Species is reported to be declining throughout its limited California range.	<b>Land Acquisition:</b> 4,100 of modeled secondary habitat acquired for Reserve System. Land acquisition adheres to species Recovery Plan. Focus on building connections between the more isolated satellite populations to contributes to <i>the Level A Strategy</i> to “work toward the establishment of a viable complex of kit fox populations (i.e., a viable metapopulation) on private and public lands throughout its geographic range”. Plan supports the Habitat <i>Protection and Population Interchange Recovery Action xiv</i> to “Protect existing kit fox habitat in the northern, northeastern, and northwestern segments of their geographic range...” (U.S. Fish and Wildlife Service 1998). Target areas include north and south of SR 152 and east of SR 152/156 interchange that have the highest potential to support species.	<b>Permanent:</b> 198 acres of modeled secondary habitat (<1%). 28 acres of modeled secondary habitat (low use) (1%). 226 acres total (<1%).	Document and assess all potential den sites for occupancy and wildlife corridor use of SR 152 crossings (e.g., bridges, culverts). Evaluate distribution changes of California ground squirrels (prey base) in response to grassland management. Determine how SR 152 affects habitat connectivity using other terrestrial mammals’ movement patterns and response to barriers.
<b>Status in Permit Area:</b> 40,892 acres of modeled habitat. 5,067 acres of modeled habitat currently protected in Type 1 open space (secondary habitat, secondary habitat low use). Four occurrence records for 1972–2002 report both den use and movement through the permit area. Genetic studies demonstrate that interbreeding occurs between individuals of the San Luis Reservoir population, southeast of the permit area, and those of Alameda and Costa Counties. It is assumed that the Pacheco–Santa Ana watershed in the southeastern part of Santa Clara County provides movement habitat between these two areas. Species status in the permit area is unknown due to lack of data.	<b>Enhancement, Restoration, and Creation:</b> All habitat enhanced. Specified management of native vegetation and limited the use of rodenticides will support sustainable prey population. Species passage will be improved across SR 152 with the placement of culverts or free span bridges and removal of median barriers. Fencing will be installed to encourage culvert and bridge use to avoid roadway crossings or to use sections without median barriers. Public education will be conducted to inform landowners on land use techniques that are more compatible with species movement and use.	<b>Temporary:</b> 46 acres of modeled secondary habitat (<1%). 6 acres of modeled secondary habitat (low use) (<1%). 52 acres total (<1%).	
<b>Conditions on Covered Activities:</b> Development guidelines ensure impacts are avoided or minimized (Condition 18). Surveys for potential breeding and denning sites will be required for projects occurring within modeled habitat as defined by this Plan. If the project does not fully avoid impacts on potential dens, preconstruction surveys will be required. Preconstruction surveys will conclude no more than two calendar days prior to construction. Preconstruction surveys written results will be submitted to USFWS and CDFG within two calendar days after survey completion and before ground disturbance start. If individuals or suitable dens are identified in survey area, minimization measures will be implemented (Condition 18). For example, during covered activities, dens will be monitored; unoccupied dens will be destroyed and use of occupied (non-natal) dens will be discouraged. During construction monitoring, a trained biologist will establish exclusion zones at least 50 feet for atypical and potential dens and at least 100 feet for known dens. If an occupied natal den is found, USFWS and CDFG will be notified immediately and the den will not be destroyed until the pups and adults have vacated and then only after further consultation with USFWS and CDFG. All construction or maintenance personnel must participate in training.			
<b>Net effects:</b> The Plan does not authorize take of San Joaquin kit fox in the form of injury or mortality. Up to 278 acres (<1%) of modeled habitat will be affected by covered activities. The Reserve System will protect a minimum of 4,100 acres of modeled secondary habitat. Within the Reserve System all habitat will be enhanced. This will result in an increase of 81% of protected modeled habitat and a total of 22% of modeled habitat protected as Type 1 open space and. Land acquisition and habitat enhancement includes elements of the <i>Level A Strategy</i> , <i>Population Interchange Recovery Action xiv</i> , and <i>Population Ecology Management Recovery Action i</i> of the species recovery plan. A network of core reserves and movement routes will protect a critical linkage for San Joaquin kit fox through the permit area to adjacent populations in Alameda and Contra Costa Counties (LAND-G9). Grassland and oak woodlands will be managed to support a sustainable prey population (GRASS-5, 6). Barriers to passage will be removed and structural improvements to facilitate movement will be implemented to improve species passage across SR 152 (LM-1–5). A public awareness campaign will encourage species-compatible land uses outside the Reserve System (GRASS-10). Development guidelines will ensure that impacts on this species from covered activities that occur outside the Reserve System are minimized (Condition 18). The Plan is likely to benefit the species in the permit area through habitat acquisition, habitat enhancement, and avoidance and minimization of direct impacts on the species.			

Table ES-2. Continued

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Tiburon Indian paintbrush (<i>Castilleja affinis</i> ssp. <i>neglecta</i>)/(E/T, 1B)</b>			
<b>Status in California:</b> 9 known occurrences. Endemic to California, its range is approximately 30 by 70 miles (north–south), and occurs in Marin, Napa, and Santa Clara Counties. Species is reported to be stable throughout its limited California range.	<b>Land Acquisition:</b> 1 occurrence added from existing open space to Reserve System.	<b>Permanent:</b> 0 occurrences.	Evaluate species response to management and habitat enhancement (e.g., grazing regimes) annually and after significant events that may have strong effects on occurrence size (e.g. fire, severe weather). Identify limiting factors of occurrence expansion through targeted research. Develop appropriate monitoring protocols to study occurrence response to experimental grazing exclusion. Monitor potential threats (e.g. feral pigs, prescribed burns) to occurrence.
<b>Status in Permit Area:</b> 2 of 9 known occurrences. No occurrences currently protected in Type 1 open space. 1 occurrence is on private land as a mitigation site for expansion of the Kirby Canyon Landfill. The easement for this occurrence will expire in 2034. The site is currently monitored and managed by the Kirby Canyon Butterfly Trust. The second occurrence, located in the North Canyon, is on private land. At the time this Plan was being developed, the landowners was in the process of finalizing a conservation easement on the site.	<b>Enhancement, Restoration, and Creation:</b> Increase the size of occurrence to at least 2,000 individuals (number will be adjusted as necessary pending research carried out during Plan implementation to assure viable populations of this species). Conservation Strategy specifies identification through targeted studies of factors limiting the expansion of extant occurrences including management and microsite needs at all life stages. Effects of livestock grazing on species will be determined. Research results will be incorporated into management plans to mitigate or remove limiting factors.	<b>Temporary:</b> N/A	
<b>Conditions on Covered Activities:</b> Plant surveys will be required during appropriate season period ( <b>Table 6-10</b> ) if a project site occurs in an area mapped as land cover associated with Tiburon Indian paintbrush ( <b>Table 3-6; Figure 3-10</b> ). The condition of any new occurrences that may be found during the permit as a result of project surveys will be documented to ensure they are not affected. Exotic plants and recreational use will be controlled in reserves to benefit the species (Condition 9). Covered activities will avoid serpentine land cover types whenever feasible during project planning (Condition 13).			
<b>Net effects:</b> No occurrences of this species will be lost as a result of covered activities. The Reserve System will protect one occurrence that is now under easement which will expire in 2034. Plan implementation will result in 100% of known occurrence protected in Type 1 open space and species management will increase the total occurrence to at least 2,000. Management will enhance habitat quality for this species, and targeted research will be conducted on factors limiting the extent of current occurrences (STUDIES-5, 16). The Reserve System occurrence will be represented in a permanent conservation seed bank unless collection would pose a threat to the occurrence’s continued existence (STUDIES-12). Development guidelines will ensure that impacts on currently undiscovered occurrences from covered activities outside the Reserve System are avoided (Condition 9). Guidelines for reserve management will ensure that recreational use will avoid species impacts (Condition 9). The Plan is likely to benefit the species in the Reserve System and throughout its range through habitat acquisition/enhancement/restoration, occurrence augmentation, and avoidance and minimization of direct impacts on the species.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Coyote ceanothus (<i>Ceanothus ferrisiae</i>)(E/-/1B)</b>			
<b>Status in California:</b> 3 known occurrences. Species is endemic to Santa Clara County where it occurs in the Mt. Hamilton Range. Species is reported to be declining throughout its limited California range.	<b>Land Acquisition:</b> 5 occurrences acquired for Reserve System, 3 known, extant occurrences and 2 newly discovered occurrences.	<b>Permanent:</b> No more than 3,650 individuals or 5% of the Anderson Dam occurrence, whichever is less.	Conduct baseline surveys of known occurrences to determine occurrence size and demography upon land acquisition. Evaluate species response to management and habitat enhancement (e.g., controlled burns, `grazing regimes) annually and after significant events that may have strong effects on occurrence size (e.g., fire, severe weather). Target research to identify factors that limit occurrence expansion. Monitor potential threats (e.g., increases in reservoir levels) to occurrences as needed.
<b>Status in Permit Area:</b> 3 of 3 known occurrences. 0 occurrences currently protected in Type 1 open space All three existing occurrences are located in the Morgan Hill area; two are near Anderson Reservoir east of U.S. 101 and the third is on the west side of U.S. 101.	<b>Enhancement, Restoration, and Creation:</b> Up to 2 new occurrences created, in lieu of acquisition, if acquisition of naturally-occurring occurrences is infeasible. Increase each occurrence to at least 5,000 individuals (number will be adjusted as necessary pending research carried out during Plan implementation to assure viable populations of this species). Conservation strategy specifies targeting the east side of Coyote Valley to site new occurrence and increase species range. Targeted research will determine limiting factors in expansion of extant occurrences, appropriate and viable propagation or planting techniques, seed sampling and harvest techniques, and will indentify suitable locations and methods for occurrence establishment. Fire and alternative vegetative management in chaparral community will be used to maintain structural diversity and canopy gaps and promote regeneration to benefit species maintenance and regeneration. Success criteria will be developed by the Implementing Entity and approved by USFWS and CDFG prior to occurrence creation.	<b>Temporary:</b> No known occurrences (0%).	
<b>Conditions on Covered Activities:</b> Development guidelines will ensure that impacts from covered activities are minimized (Condition 20). Plant surveys will be required during appropriate season period ( <b>Table 6-10</b> ) if the project site occurs in an area mapped as land cover associated with coyote ceanothus ( <b>Table 3-6; Figure 3-10</b> ). Individuals to be removed by covered activities will be salvaged to the extent possible using appropriate plant salvage techniques and a new separate occurrence will be established in suitable habitat (Condition 19). The condition of each covered plant occurrence will be documented to ensure that occurrences are protected within the Reserve System are in as good or better condition than those lost to covered activities. Exotic plants and recreational use will be controlled within reserves to benefit the species (Condition 9). Covered activities will avoid serpentine land cover types whenever feasible during project planning (Condition 13). If serpentine cannot be avoided, minimization measures described in Condition 13 will be followed.			
<b>Net effects:</b> No more than 3,650 individuals or 5% of the Anderson Dam occurrences (including both occurrences on either side of the Dam), whichever is less, will be affected by covered activities. The Reserve System will protect 3 currently unprotected known occurrences in the permit area and 2 new occurrences will be created if acquisition of any newly-discovered occurrences is infeasible (LAND-P1, STUDIES-13–15). This will result in protection of a 100% of known occurrences and a total of 5 occurrences in Type 1 open space. Management will enhance habitat quality for this species, and targeted research will be conducted on factors limiting the extent of current occurrences (STUDIES-5, 11; CHAP-1, 2; LM-8, 12). As part of species Recovery Plan implementation, a permanent conservation seed bank will be established in the National Collection of Endangered Plants. All known occurrences in the Reserve System will be represented in a permanent conservation seed bank unless collection would pose a threat to the occurrence’s continued existence (STUDIES-12). The Plan is likely to benefit the species in the Reserve System and throughout its range through habitat acquisition/enhancement/restoration, occurrence augmentation, and avoidance and minimization of direct impacts on the species.			

Table ES-2. Continued

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Mt. Hamilton thistle (<i>Cirsium fontinale</i> var. <i>campylon</i>)(-/-/1B)</b>			
<b>Status in California:</b> 48 known occurrences. Species is endemic to the San Francisco Bay area, with two clusters of occurrences: one in the Mt. Hamilton Ranges, the other in the hills adjacent to the northern Santa Clara Valley, occurring on serpentine soils in seeps and springs and along intermittent and perennial streams, at elevations of 320–2,900 feet. Occurs in Santa Clara, Stanislaus, and Alameda Counties. Data are insufficient to characterize species status across its range; however, species is believed to be stable. Further study is necessary to confirm.	<b>Land Acquisition:</b> 20 known occurrences acquired for Reserve System. 2 known occurrences added to Reserve System from existing open space. 150 acres modeled habitat acres modeled habitat acquired for Reserve System. 60 acres modeled habitat added to Reserve System from existing open space. Target sites include drainages or spring systems that support species, such as, spring-fed serpentine drainages on Coyote Ridge that flow west into Coyote Creek, drainages that flow into San Felipe Creek, and other suitable habitat in the Santa Cruz Mountains between Calero County Park and Almaden Quicksilver County Park, and on Tulare Hill. An effort will be made to stratify protection and acquire sites on both sides of Coyote Valley to ensure geographic diversity in protected occurrences.	<b>Permanent:</b> 6 known occurrences; 26 acres of modeled primary habitat (5%).	Determine or estimate the number of individuals in known occurrences of covered plants and whether undiscovered occurrences occur on Reserve System acquisitions. Evaluate species response to management and habitat enhancement (e.g., grazing regimes) and after significant events that may have strong effects on occurrence size (e.g., fire, severe weather). Target research to identify factors that limit occurrence expansion. Monitor potential threats (e.g., insect herbivores, livestock grazing) to occurrences as needed.
<b>Status in Permit Area:</b> 40 of 48 known occurrences; 487 acres of modeled habitat. 2 occurrences currently protected in Type 1 open space. 55 acres of modeled habitat currently protected in Type 1 open space. There are occurrence estimates for 34 of the known occurrences of this species, from as early as 1983 up to as recently as 2006. These estimates range from 1 to 4,500 individuals, and the total estimated population of all occurrences is 28,933. The total number may be higher as species numbers are likely to fluctuate from year to year in response to annual fluctuations in rainfall and runoff into serpentine seeps.	<b>Enhancement, Restoration, and Creation:</b> Increase each occurrence to at least 2,000 individuals (number will be adjusted as necessary pending research carried out during Plan implementation to assure viable populations of this species). Conservation Strategy specifies determining limiting factors to occurrence expansion, including life stage and microsite needs, through targeted research. Livestock will be experimentally excluded to determine occurrence response. Hydrologic systems will be managed and maintained to provide species habitat.	<b>Temporary:</b> 4 acres of modeled primary habitat (<1%).	
<b>Conditions on Covered Activities:</b> Development guidelines will ensure that impacts from covered activities are minimized (Condition 20). Plant surveys will be required during the appropriate season period ( <b>Table 6-10</b> ) if the project site occurs in an area mapped as land cover associated with Mt. Hamilton thistle ( <b>Table 3-6; Figure 3-10</b> ). Occurrences to be removed by covered activities will be salvaged to the extent possible using appropriate plant salvage techniques and a new separate occurrence will be established in suitable habitat [not mentioned above] (Condition 19). The condition of each covered plant occurrence will be documented to ensure that occurrences are protected within the Reserve System are in as good or better condition than those lost to covered activities. Exotic plants and recreational use will be controlled within reserves to benefit the species (Condition 9). Covered activities will avoid serpentine land cover types whenever feasible during project planning (Condition 13). If serpentine cannot be avoided, minimization measures described in Condition 13 will be followed.			
<b>Net effects:</b> Up to 6 known occurrences and up to 30 acres (6%) of modeled habitat will be affected by covered activities. The Reserve System will protect a minimum of 210 acres of modeled habitat, including 22 known occurrences (LAND-P6). This will result in a 384% increase of lands managed as species habitat, 24 total occurrences managed in Type 1 open space, and 54% of modeled habitat protected as Type 1 open space. Habitat management includes maintaining hydrologic systems required for species habitat. Targeted studies will be conducted to test the effects on livestock on occurrences and to investigate factors that can be used to identify suitable locations for new occurrence establishment, propagation or planting techniques, alternative techniques for occurrence establishment, and factors limiting the extent of current occurrences (STUDIES-5, 16). As part of Recovery Plan implementation, a permanent conservation seed bank will be established in the National Collection of Endangered Plants. All known occurrences in the Reserve System will be represented in a permanent conservation seed bank unless collection would pose a threat to the occurrence’s continued existence (STUDIES-12). The Plan is likely to benefit the species in the Reserve System and throughout its range through habitat acquisition/enhancement/restoration, occurrence augmentation, and avoidance and minimization of direct impacts on the species.			

Table ES-2. Continued

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Santa Clara Valley dudleya (<i>Dudleya abramsii</i> ssp. <i>setchellii</i>)(E/-/1B)</b>			
<b>Status in California:</b> 209 known occurrences. Species is endemic to Santa Clara County, found in the vicinity of Coyote Valley from San José south about 20 miles to San Martin, at elevations of 300–900 feet. Data are insufficient to characterize species status across its range; however, species is believed to be stable, although further study is necessary to confirm.	<b>Land Acquisition:</b> 44 known occurrences acquired for Reserve System. 11 known occurrences added to Reserve System from existing open space. Sites will be stratified to protect occurrence on both sides of Coyote Valley to ensure geographic diversity in protected occurrences. This includes the majority of known occurrences along Coyote Ridge, in the Santa Teresa Hills and Tulare Hill (4), west of Calero County Park (2), and north of Morgan Hill (1). Incorporation of portions of Santa Teresa, Calero, and Almaden Quicksilver County Parks into the Reserve System add 10 occurrences for existing open space to be protected as Type 1 open space. The protected land will include a buffer of 150 meters (500 feet), if feasible, around each occurrence to reduce external influences and allow expansion of the occurrence.	<b>Permanent:</b> 11 known occurrences.	Conduct baseline occurrence surveys in all suitable habitat to evaluate known occurrences and document new occurrences. Delineate operational “boundary” for discrete occurrences for monitoring and management purposes. Evaluate species response to management and habitat enhancement (e.g., grazing regimes) annually and after significant events that may have strong effects on occurrence size (e.g., fire, severe weather). Target research to identify factors that limit occurrence expansion. Monitor potential threats (e.g., fires, livestock grazing) to occurrences as needed.
<b>Status in Permit Area:</b> 207 of 209 known occurrences. 2 occurrences currently protected in Type 1 open space. Occurrence estimates are only available for 46 occurrences that total 72,500 individuals.	<b>Enhancement, Restoration, and Creation:</b> Increase each occurrence to at least 2,000 individuals (number will be adjusted as necessary pending research carried out during Plan implementation to assure viable populations of this species). Conservation Strategy specifies seeding or transplanting adults from large occurrences to suitable unoccupied rock outcrops in existing occurrences. Limiting factors to occurrence expansion, including life stage and microsite needs, will be determined through targeted research. Livestock will be experimentally excluded to determine occurrence response.	<b>Temporary:</b> N/A	
<b>Conditions on Covered Activities:</b> Development guidelines will ensure that impacts on Santa Clara Valley dudleya from covered activities are minimized (Condition 20). Plant surveys will be required during the appropriate season period ( <b>Table 6-10</b> ) if the project site occurs in an area mapped as land cover associated with Santa Clara Valley dudleya ( <b>Table 3-6; Figure 3-10</b> ). Occurrences to be removed by covered activities will be salvaged to the extent possible using appropriate plant salvage techniques, and a new separate occurrence will be established in suitable habitat (Condition 19). The condition of each covered plant occurrence will be documented to ensure that occurrences are protected within the Reserve System are in as good or better condition than those lost to covered activities. Exotic plants and recreational use will be controlled within reserves to benefit the species (Condition 9). Covered activities will avoid serpentine land cover types whenever feasible during project planning (Condition 13). If serpentine cannot be avoided, minimization measures described in Condition 13 will be followed.			
<b>Net effects:</b> Up to 11 known will be affected by covered activities. The Reserve System will protect 55 known occurrences in permit area (LAND-P2). This will result in 57 occurrences protected and managed in Type 1 open space. Management will enhance habitat quality for this species, and targeted studies will be conducted on factors limiting the extent of current occurrences in order to increase each occurrence to at least 2,000 individuals (STUDIES-5, 16). As part of Recovery Plan implementation, a permanent conservation seed bank will be established in the National Collection of Endangered Plants. All known occurrences in the Reserve System will be represented in a permanent conservation seed bank unless collection would pose a threat to the occurrence’s continued existence (STUDIES-12). The Plan is likely to benefit the species in the Reserve System and throughout its range through habitat acquisition/enhancement/restoration, occurrence augmentation, and avoidance and minimization of direct impacts on the species.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Fragrant fritillary (<i>Fritillaria liliacea</i>)/(-/-/1B)</b>			
<b>Status in California:</b> 59 known occurrences. Species is endemic to western central California, ranging from Sonoma and Solano Counties south to Monterey County.	<b>Land Acquisition:</b> 3 occurrences acquired for Reserve System. 1 known occurrence added to Reserve System from existing open space. 23,000 acres modeled habitat acquired for Reserve System. 4,000 acres modeled habitat added to Reserve System from existing open space. 3 unprotected occurrences will be targeted for acquisition. Two occurrences will be protected along Coyote Ridge southeast of Metcalf Canyon and northeast of Morgan Hill. The third occurrence will be located outside of Metcalf Canyon, preferably east of the valley. A fourth occurrence in Calero County Park will be incorporated into the Reserve System as Type 1 open space. The protected land will include a 500-foot buffer around each occurrence to reduce external influences and allow expansion of the occurrence if biologically feasible and appropriate.	<b>Permanent:</b> 1 known occurrence; 550 acres of modeled primary habitat (6%). 2,729 acres of modeled secondary habitat (2%). 3,279 acres total (2%).	Determine or estimate the number of individuals in known occurrences of covered plants and whether undiscovered occurrences occur on Reserve System acquisitions. Evaluate species response to management and habitat enhancement (e.g., grazing regimes) and after significant events that may have strong effects on occurrence size (e.g., fire, severe weather). Target research to identify factors that limit occurrence expansion. Monitor potential threats (e.g., fires, livestock grazing) to occurrences as needed.
<b>Status in Permit Area:</b> 8 of 59 known occurrences; 165,455 acres modeled habitat. 0 occurrences currently protected in Type 1 open space; 16,371 acres of modeled habitat currently protected in Type 1 open space (primary and secondary habitat). 35 occurrences have size estimates, for a total of 16,383 individuals.	<b>Enhancement, Restoration, and Creation:</b> Conservation Strategy specifies identification of factors limiting occurrence expansion, factors affecting establishment and maintenance of new occurrences, life stage and specific microsite needs, and effects of land management on occurrence establishment and survival.	<b>Temporary:</b> 59 acres of modeled primary habitat (<1%). 655 acres of modeled secondary habitat (<1%). 714 acres total (<1%).	
<b>Conditions on Covered Activities:</b> Development guidelines will ensure that impacts from covered activities are minimized. Plant surveys will be required during the appropriate season period ( <b>Table 6-10</b> ) if the project site occurs in an area mapped as land cover associated with fragrant fritillary ( <b>Table 3-6; Figure 3-10</b> ). Occurrences to be removed by covered activities will be salvaged to the extent possible using appropriate plant salvage techniques and a new separate occurrence will be established in suitable habitat [not mentioned above] (Condition 19). The condition of each covered plant occurrence will be documented to ensure that occurrences are protected within the Reserve System are in as good or better condition than those lost to covered activities. Exotic plants and recreational use will be controlled in reserves to benefit the species (Condition 9). Covered activities will avoid serpentine land cover types whenever feasible during project planning (Condition 13). If serpentine cannot be avoided, minimization measures described in Condition 13 will be followed.			
<b>Net effects:</b> Up to 1 known occurrence and 3,993 acres (2%) of modeled habitat will be affected by covered activities. The Reserve System will protect a minimum of 27,000 acres of modeled habitat, including four known occurrences (LAND-P8). This will result in a 226% increase of lands managed as species habitat, protection and management of a total of 4 occurrences, and 26% of modeled habitat as Type 1 open space. Targeted studies will identify factors limiting occurrence expansion and test the effects of livestock grazing (STUDIES-5, 16). All known occurrences in the Reserve System will be represented in a permanent conservation seed bank unless collection would pose a threat to the occurrence’s continued existence (STUDIES-12). The Plan is likely to benefit the species in the Reserve System and throughout its range through habitat acquisition/enhancement/restoration, occurrence augmentation, and avoidance and minimization of direct impacts on the species.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Loma Prieta hoita (<i>Hoita strobilina</i>)(-/-/1B)</b>			
<b>Status in California:</b> 26 known occurrences. Endemic to California, species occurs primarily in the Santa Cruz Mountains of Santa Clara and Santa Cruz Counties. The species also occurs in the Diablo Range in Santa Clara, Alameda, and Contra Costa Counties. Data are insufficient to determine global and regional status.	<b>Land Acquisition:</b> 1 known occurrence acquired for Reserve System. 3 known occurrences added to Reserve System from existing open space. 10,000 acres modeled habitat acquired for Reserve System. 4,100 acres modeled habitat added to Reserve System from existing open space. Targeted acquisition includes an occurrence on the east side of the Santa Clara Valley, just east of US 101, south of Motorcycle Park. Three additional occurrences will be added to the Reserve System as Type 1 open space through the incorporation of Santa Teresa, Almaden Quicksilver, and Calero County Parks. All occurrences will protect a biologically appropriate buffer around known occurrence to reduce external influences and allow for occurrence expansion.	<b>Permanent:</b> No known occurrences; 2,117 acres of modeled primary habitat (2%) 266 acres of modeled secondary habitat (1%). 2,383 acres total (2%).	Determine or estimate the number of individuals in known occurrences of covered plants and whether undiscovered occurrences occur on Reserve System acquisitions. Evaluate species response to management and habitat enhancement (e.g., grazing regimes) and after significant events that may have strong effects on occurrence size (e.g., fire, severe weather). Target research to identify factors that limit occurrence expansion. Monitor potential threats (e.g., feral pig rooting) to occurrences as needed.
<b>Status in Permit Area:</b> 14 of 26 known occurrences; 121,871 acres of modeled habitat. 1 occurrence currently protected in Type 1 open space. 17,276 acres of modeled habitat currently protected in Type 1 open space (primary and secondary habitat).	<b>Enhancement, Restoration, and Creation:</b> Conservation Strategy specifies identifying factors limiting the expansion of known occurrences, life stage and specific microsite needs, and effects of land management on occurrence establishment and survival.	<b>Temporary:</b> 413 acres of modeled primary habitat (<1%). 60 acres of modeled secondary habitat (<1%). 473 acres (<1%).	
<b>Conditions on Covered Activities:</b> Development guidelines will ensure that impacts from covered activities are minimized (Condition 20). Plant surveys will be required during the appropriate season period ( <b>Table 6-10</b> ) if the project site occurs in an area mapped as land cover associated with Loma Prieta hoita ( <b>Table 3-6; Figure 3-10</b> ). Occurrences to be removed by covered activities will be salvaged to the extent possible using appropriate plant salvage techniques and a new separate occurrence will be established in suitable habitat (Condition 19). The condition of each covered plant occurrence will be documented to ensure that occurrences are protected within the Reserve System are in as good or better condition than those lost to covered activities. Exotic plants and recreational use will be controlled in reserves to benefit the species (Condition 9).			
<b>Net effects:</b> No known occurrences and up to 2,856 acres (2%) of modeled habitat will be affected by covered activities. The Reserve System will protect a minimum of 14,100 acres of modeled habitat, including four known occurrence (LAND-P12). This will result in an 82% increase of lands managed as species habitat, a total of 5 managed occurrences in Type 1 open space, and 26% of modeled habitat protected as Type 1 open space. Targeted studies will identify factors limiting occurrence expansion (STUDIES-5). All known occurrences in the Reserve System will be represented in a permanent conservation seed bank unless collection would pose a threat to the occurrence’s continued existence (STUDIES-12). The Plan is likely to benefit the species in the Reserve System and throughout its range through habitat acquisition/enhancement/restoration, occurrence augmentation, and avoidance and minimization of direct impacts on the species.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Smooth lessingia (<i>Lessingia micradenia</i> var. <i>glabrata</i>)</b> (-/-1B)			
<b>Status in California:</b> 39 known occurrences. Species is endemic to Santa Clara County on the eastern slopes of the Santa Cruz Mountains and the hills adjacent to the Santa Clara Valley. Data are insufficient to determine global and regional status; however, all documented occurrences are presumed to be extant.	<b>Land Acquisition:</b> 7 known or new occurrences acquired for Reserve System, 5 known occurrences added to Reserve System from existing open space. 12 new occurrences (if discovered) acquired for Reserve System. 4,000 acres modeled habitat acquired for Reserve System. 1,100 acres modeled habitat added to Reserve System from existing open space. Targeted acquisition are located on the west side of US 101 in the Santa Cruz Mountains foothills, on serpentine areas between Tulare Hill and Mount Madonna County Park. Two additional occurrences will be added to the Reserve System as Type 1 open space from Calero and Mount Madonna County Parks. All occurrences will be protected by a 500-foot buffer around occurrences to reduce external influences and allow for occurrence expansion.	<b>Permanent:</b> 6 known occurrences; 550 acres of modeled primary habitat (5%).	Determine or estimate the number of individuals in known occurrences of covered plants and whether undiscovered occurrences occur on Reserve System acquisitions. Evaluate species response to management and habitat enhancement (e.g., grazing regimes) and after significant events that may have strong effects on occurrence size (e.g., fire, severe weather). Target research to identify factors that limit occurrence expansion. Monitor potential threats (e.g., fires, livestock grazing) to occurrences as needed.
<b>Status in Permit Area:</b> 39 of 39 known occurrences; 10,491 acres modeled habitat. 3 occurrences currently protected in Type 1 open space; 1,268 acres of modeled habitat currently protected in Type 1 open space. 16 of the 33 known occurrences have size estimates totaling 95,213.	<b>Enhancement, Restoration, and Creation:</b> Up to 12 occurrences created, in lieu of acquisition, if acquisition of naturally-occurring occurrences is infeasible. Increase the size of each occurrence to at least 2,000 individuals. Conservation Strategy specifies targeted research to identify limiting factors to occurrence expansion, including life stage and microsite needs, and effects of land management on occurrence establishment and survival. Livestock will be experimentally excluded to determine occurrence response. Success criteria will be developed by the Implementing Entity and approved by USFWS and CDFG prior to occurrence creation.	<b>Temporary:</b> 68 acres of modeled primary habitat (<1%).	
<b>Conditions on Covered Activities:</b> Development guidelines will ensure that impacts from covered activities are minimized (Condition 20). Plant surveys will be required during the appropriate season period ( <b>Table 6-10</b> ) if the project site occurs in an area mapped as land cover associated with smooth lessingia ( <b>Table 3-6; Figure 3-10</b> ). Occurrences to be removed by covered activities will be salvaged to the extent possible using appropriate plant salvage techniques and a new separate occurrence will be established in suitable habitat (Condition 19). The condition of each covered plant occurrence will be documented to ensure that occurrences are protected within the Reserve System are in as good or better condition than those lost to covered activities. Exotic plants and recreational use will be controlled in reserves to benefit the species (Condition 9). Covered activities will avoid serpentine land cover types whenever feasible during project planning (Condition 13). If serpentine cannot be avoided, minimization measures described in Condition 13 will be followed.			
<b>Net effects:</b> Up to 6 known occurrences and 618 acres (6%) of modeled habitat will be affected by covered activities. The Reserve System will protect a minimum of 5,100 acres of modeled habitat, including 12 known occurrences (LAND-P7). At least 12 new occurrences will be found and acquired or established in suitable unoccupied habitat. This will result in a 427% increase of lands managed as species habitat, protection and management of 27 occurrences in Type 1 open space, and protection of a total of 61% of modeled habitat as Type 1 open space. Targeted studies will be conducted to identify factors limiting the extent of current occurrences and to test the effects of livestock grazing on occurrences (STUDIES-5, 14, 16). As part of Recovery Plan implementation, a permanent conservation seed bank will be established in the National Collection of Endangered Plants. All known occurrences in the Reserve System will be represented unless collection would pose a threat to the occurrence’s continued existence (STUDIES-12). The Plan is likely to benefit the species in the Reserve System and throughout its range through habitat acquisition/enhancement/restoration, occurrence augmentation, and avoidance and minimization of direct impacts on the species.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Metcalf Canyon jewelflower (<i>Streptanthus albidus</i> ssp. <i>albidus</i>)/(FE/1B)</b>			
<b>Status in California:</b> 11 known occurrences. Species is endemic to Santa Clara County, CA, with its range extending approximately 20 miles from San José south to Anderson Lake. Species is reported to be declining throughout its limited California range.	<b>Land Acquisition:</b> 3 known occurrences acquired for Reserve System. 10 new occurrences, if found, acquired for Reserve System. 3,200 acres modeled habitat acquired for Reserve System. 1,000 acres modeled habitat added to Reserve System from existing open space. Acquire additional land on north side of Tulare Hill for reintroduction site. The protected land will include a buffer of 150 meters (500 feet), if feasible, around each occurrence to reduce external influences and allow expansion of the occurrence. 68 occurrences of an unidentified jewelflower on Coyote Ridge near Metcalf Canyon will likely be protected in the Reserve System. Due to the proximity of known occurrences, some are likely to be Metcalf Canyon jewelflower.	<b>Permanent:</b> 2 known occurrences; 550 acres of modeled primary habitat (7%).	Conduct baseline occurrence surveys in all suitable habitat to evaluate known occurrences and document new occurrences. Evaluate species response to management and habitat enhancement (e.g., grazing regimes) annually and after significant events that may have strong effects on occurrence size (e.g., fire, severe weather). Target research to identify factors that limit occurrence expansion. Monitor potential threats (e.g., fires, livestock grazing) to occurrences as needed.
<b>Status in Permit Area:</b> 10 of 11 known occurrences; 8,105 acres modeled habitat. 1 occurrence currently protected in Type 1 open space; 984 acres of modeled habitat currently protected in Type 1 open space.	<b>Enhancement, Restoration, and Creation:</b> Up to 10 new occurrences created, in lieu of acquisition, if acquisition of naturally-occurring occurrences is infeasible. Increase each occurrence to at least 2,000 individuals (number will be adjusted as necessary pending research carried out during Plan implementation to assure viable populations of this species). Conservation Strategy specifies targeting Tulare Hill on west side of valley for occurrence creation. Targeted research will be conducted to identify limiting factors in expansion of extant occurrences, appropriate and viable propagation or planting techniques, and seed sampling and harvest techniques, as well as to determine suitable locations and methods for occurrence establishment. Success criteria will be developed by the Implementing Entity and approved by USFWS and CDFG prior to occurrence creation.	<b>Temporary:</b> 62 acres of modeled primary habitat (<1%).	
<b>Conditions on Covered Activities:</b> Development guidelines will ensure that impacts from covered activities are minimized (Condition 20). Plant surveys will be required during the appropriate season period ( <b>Table 6-10</b> ) if the project site occurs in an area mapped as land cover associated with Metcalf Canyon jewelflower ( <b>Table 3-6; Figure 3-10</b> ). Occurrences to be removed by covered activities will be salvaged to the extent possible using appropriate plant salvage techniques, and a new separate occurrence will be established in suitable habitat (Condition 19). The condition of each covered plant occurrence will be documented to ensure that occurrences are protected within the Reserve System are in as good or better condition than those lost to covered activities. Exotic plants and recreational use will be controlled within reserves to benefit the species (Condition 9). Covered activities will avoid serpentine land cover types whenever feasible during project planning (Condition 13). If serpentine cannot be avoided, minimization measures described in Condition 13 will be followed.			
<b>Net effects:</b> Up to 2 known occurrences and 612 acres (8%) of modeled habitat will be affected by covered activities. The Reserve System will protect 4,200 acres of modeled habitat, including 3 of 10 known occurrences that are currently unprotected in the permit area. At least 10 new occurrences will be found and acquired and/or created in suitable unoccupied habitat (LAND-P3, P4). This will result in a 427% increase of lands managed as species habitat, protection of a total of 4 known occurrences in Type 1 open space and 10 newly discovered and/or created occurrences, and protection of 64% of modeled habitat as Type 1 open space. Conservation Strategy implementation will increase the total number of extant occurrences to 21 in California, including 14 occurrences protected in Type 1 open space. Management will enhance habitat quality for this species, and targeted studies will be conducted on factors limiting the extent of current occurrences (STUDIES 5, 14, 15, 17). As part of Recovery Plan implementation, a permanent conservation seed bank will be established in the National Collection of Endangered Plants. All known occurrences in the Reserve System will be represented unless collection would pose a threat to the occurrence’s continued existence (STUDIES-12).The Plan is likely to benefit the species in the Reserve System and throughout its range through habitat acquisition/enhancement/restoration, occurrence augmentation, and avoidance and minimization of direct impacts on the species.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<b>Most beautiful jewelflower (<i>Streptanthus albidus</i> ssp. <i>peramoenus</i>)/(-/-1B)</b>			
<b>Status in California:</b> 86 known occurrences. Species is endemic to California, found in the northern South Coast Ranges of Contra Costa, Alameda, and Santa Clara Counties. Species is reported to be declining throughout its limited California range.	<b>Land Acquisition:</b> 9 known occurrences acquired for Reserve System. 8 known occurrences added to the Reserve System from existing open space. 4,000 acres modeled habitat acquired for Reserve System. 1,700 acres modeled habitat added to Reserve System from existing open space. Target areas include suitable habitat and occurrences along Coyote Ridge, in Santa Teresa Hills, west of Chesbro Reservoir, near Morgan Hill and in the southern end of the permit area in the Santa Cruz Mountain foothills. Eight occurrences will be added to the Reserve System from Alamaden Quicksilver, Calero, and Santa Teresa County Parks as Type 1 open space. All occurrences will be buffered by 150 meters (500 feet) to reduce external influences and allow expansion of the occurrence. 68 occurrences of an unidentified jewelflower on Coyote Ridge near Metcalf Canyon will likely be acquired for Reserve System. Due to the proximity of known occurrences, some are likely to be most beautiful jewelflower.	<b>Permanent:</b> 6 known occurrences; 550 acres of modeled primary habitat (4%).	Determine or estimate the number of individuals in known occurrences of covered plants and whether undiscovered occurrences occur on Reserve System acquisitions. Evaluate species response to management and habitat enhancement (e.g., grazing regimes) and after significant events that may have strong effects on occurrence size (e.g., fire, severe weather). Target research to identify factors that limit occurrence expansion. Monitor potential threats (e.g., fires, livestock grazing) to occurrences as needed.
<b>Status in Permit Area:</b> 39 of 86 known occurrences; 14,362 acres modeled habitat. 3 occurrences currently protected in Type 1 open space; 1,500 acres of modeled habitat currently protected in Type 1 open space (primary and secondary habitat).	<b>Enhancement, Restoration, and Creation:</b> Increase each occurrence to at least 2,000 individuals (number will be adjusted as necessary pending research carried out during Plan implementation to assure viable populations of this species). Conservation Strategy specifies investigation of species reproductive biology and demography. Targeted research will identify factors limiting occurrence expansion, life stage and specific microsite needs, and effects of land management on occurrence establishment and survival.	<b>Temporary:</b> 92 acres of modeled primary habitat (<1%).	
<b>Conditions on Covered Activities:</b> Development guidelines will ensure that impacts from covered activities are minimized (Condition 20). Plant surveys will be required during the appropriate season period ( <b>Table 6-10</b> ) if the project site occurs in an area mapped as land cover associated with most beautiful jewelflower ( <b>Table 3-6; Figure 3-10</b> ). Occurrences to be removed by covered activities will be salvaged to the extent possible using appropriate plant salvage techniques and a new separate occurrence will be established in suitable habitat (Condition 19). The condition of each covered plant occurrence will be documented to ensure that occurrences are protected within the Reserve System are in as good or better condition than those lost to covered activities. Exotic plants and recreational use will be controlled in reserves to benefit the species (Condition 9). Covered activities will avoid serpentine land cover types whenever feasible during project planning (Condition 13). If serpentine cannot be avoided, minimization measures described in Condition 13 will be followed.			
<b>Net effects:</b> Up to 6 known occurrences and 642 acres (4%) of modeled primary habitat will be affected by covered activities. The Reserve System will protect a minimum of 5,700 acres of modeled habitat, including 17 known occurrences (LAND-P5). This will result in a 380% increase of lands managed as species habitat and protection of a total of 20 occurrences as Type 1 open space, and a total of 50% of modeled habitat protected as Type 1 open space. Targeted studies will identify factors limiting the extent of current occurrences and suitable propagation or planting techniques for new occurrence establishment (STUDIES-5, 14, 17). As part of Recovery Plan implementation, a permanent conservation seed bank will be established in the National Collection of Endangered Plants of all known occurrence is Reserve System (STUDIES-12). The Plan is likely to benefit the species in the Reserve System and throughout its range through habitat acquisition/enhancement/restoration, occurrence augmentation, and avoidance and minimization of direct impacts on the species.			

Species/Status (Federal/State/CNPS) <sup>1</sup>	Acquisition <sup>2</sup> , Enhancement, Restoration, and Creation	Impacts <sup>3,4</sup>	Monitoring <sup>5</sup>
<sup>1</sup> Status <b>Federal</b> E      Federally Listed as Endangered T      Federally Listed as Threatened MBTA   Migratory Bird Treaty Act <b>State</b> E      State Listed as Endangered T      State Listed as Threatened SR      State Listed as Rare CSC      California Special Concern Species FP      Fully Protected <b>California Native Plant Society</b> 1B      Rare, Threatened, or Endangered in California and Elsewhere			<sup>2</sup> All land acquired as part of Reserve System will be protected as Type 1 open space. This includes land added to the Reserve System from existing open space. For many covered plant species, additional impacts are allowed under certain circumstances if additional occurrences are discovered during the permit term. See Table 5-16 for details on occurrence acquisition requirements if additional occurrences are discovered and impacts require additional protection. <sup>3</sup> Habitat was only modeled within the permit area. When models were developed, impacts are provided in terms of percent of modeled habitat. See Section 5.3.1 and plant species-specific conservation strategy discussions (Sections 5.4.12–5.4.21) for details for plant acquisition requirements (i.e., condition, location, timing). <sup>4</sup> It is expected that new occurrences of many of the covered plants will be discovered both within the impact areas and the Reserve System. In many cases, it is warranted to allow additional impacts to covered plants beyond the occurrences known at this time, as long as new occurrences are found and protected in the Reserve System before the impacts occur. A summary of number of known occurrences required in the permit area, increased take limit, and required number of occurrences protected in the Reserve System is provided in <b>Table 5-16</b> . <sup>5</sup> For complete suggested monitoring tasks, see Chapter 7, Section 7.3.3.

# Chapter 1

## Introduction

*Preparation of this document was funded in part from the Cooperative Endangered Species Conservation Fund (Section 6) Planning Grants administered by the California Department of Fish and Game through Agreements # P0630005, P0630017 and P0882006. The Agreements, which are for use of \$1,107,868 of federal funding, are for several work products including this document.*

## 1.1 Overview

The Santa Clara Valley Habitat Plan (or Plan) is intended to provide an effective framework to protect, enhance, and restore natural resources in specific areas of Santa Clara County, while improving and streamlining the environmental permitting process for impacts on threatened and endangered species. The entities listed below have prepared this Plan.

- County of Santa Clara (County).
- City of San José.
- City of Morgan Hill.
- City of Gilroy.
- Santa Clara Valley Water District (SCVWD).
- Santa Clara Valley Transportation Authority (VTA).

These entities are collectively referred to as the *Local Partners*. The Local Partners intend the Plan to allow for reasonable development, growth, and needed infrastructure construction and maintenance while accommodating the Plan's conservation goals and complying with state and federal regulatory requirements. The Local Partners are collectively known as the *Permittees*.

### 1.1.1 Mission Statement

The Local Partners and key stakeholders, participating in a goal-setting process, developed a set of broad program goals that collectively serve as the mission statement for this Plan. The program goals are divided into five themes.

## Biological Resources and Conservation

- Protect, enhance, and restore ecosystem integrity and functionality for threatened and endangered species.
- Enhance the diversity of plant and animal communities.
- Conserve habitat and contribute to the recovery of species listed or likely to be listed under the federal Endangered Species Act (ESA) or the California Endangered Species Act (CESA).

## Multi-Purpose and Benefit Plan

- Preserve and enhance watersheds to protect beneficial uses of water and to provide flood protection for Santa Clara County.
- Provide appropriate levels of public access in habitat areas in a manner compatible with conservation goals.
- Facilitate economic growth compatible with approved local land use plans.
- Preserve agricultural viability.
- Integrate the strategies of the Plan with public and private potential partners wherever possible.
- Develop a Plan with a variety of implementation measures to attract multiple funding sources.
- Allocate costs of the Plan equitably among the Local Partners.
- Develop Plan strategies that build on the governmental capacities of all Local Partner jurisdictions.

## Public Participation

- Provide an open public process in developing and implementing the Plan.

## Regulatory Compliance

- Provide a comprehensive, coordinated, and standardized mitigation and compensation plan such that regulations on public and private actions will be applied equally and consistently, reducing delays, expenses, and regulatory duplication.
- Streamline the endangered species permitting process for the covered activities.

## Effective and Efficient Implementation

- Provide a basis for the Permittees to obtain endangered species permits for public projects including those associated with uninterrupted water supply, flood protection, watershed activities, recreation, transportation, and other government functions.
- Provide a basis for private projects to gain permit authorization through local agencies.
- Create efficient reserve unit management plans that complement existing monitoring and adaptive management efforts of the Permittees and other land management entities in the study area and the region.

### 1.1.2 Purpose

The purpose of this Plan is to protect and enhance ecological diversity and function in the greater portion of Santa Clara County, while allowing appropriate and compatible growth and development in accordance with applicable laws. To this end, the Plan describes how to avoid, minimize, and mitigate impacts on endangered and threatened species, thereby addressing the permitting requirements relevant to these species for activities conducted in the Plan area by the Permittees. These activities (i.e., *covered activities*) include urban and rural growth and a variety of road, water, and other needed infrastructure construction and maintenance activities. The Plan also describes the responsibilities associated with operating and maintaining the new habitat reserves that will be created to mitigate anticipated impacts resulting from growth and development activities.

This Plan is both a habitat conservation plan (HCP) intended to fulfill the requirements of the ESA and a natural community conservation plan (NCCP) to fulfill the requirements of the California Natural Community Conservation Planning Act (NCCP Act). As an NCCP, this Plan not only addresses impact mitigation, but will also contribute to the recovery and delisting of listed species and help preclude the need to list additional species in the future. The Local Partners are voluntarily preparing this Plan as an NCCP to provide a higher level of conservation for the benefit of natural resources in Santa Clara County than is strictly required for ESA compliance. An NCCP also provides greater regulatory benefits and greater opportunities for state and federal funding than do other permitting options under state law.

In summary, this Plan will achieve the specific objectives listed below.

- Provide comprehensive species, natural community, landscape, and ecosystem conservation in the study area.
- Contribute to the recovery of endangered species in Santa Clara County and northern California.
- Protect and enhance biological and ecological diversity in the county.

- Establish a regional system of habitat reserves to preserve, enhance, restore, manage, and monitor native species and the habitats and ecosystems upon which they depend.
- Enhance and restore stream and riparian systems outside the habitat reserves to provide additional benefit to native fish and other stream-dwelling species.
- Allow issuance of permits to the Permittees for lawful incidental take<sup>1</sup> of species listed as threatened or endangered pursuant to ESA and CESA.
- Provide a means for the local agencies receiving permits to extend the incidental take authorization to private entities subject to their jurisdiction, bringing endangered species permitting under local control.
- Streamline and simplify the process for future incidental take authorization of currently nonlisted species that may become listed during the permit term.
- Standardize avoidance, minimization, mitigation, and compensation requirements of the ESA, CESA, NCCP Act, California Environmental Quality Act (CEQA), National Environmental Policy Act (NEPA), and other applicable laws and regulations relating to biological and natural resources within the planning area, so that public and private actions will be governed equally and consistently, thus reducing delays, expenses, and regulatory duplication.
- Provide a less costly, more efficient project review process that will result in greater conservation than the current project-by-project, species-by-species endangered species compliance process.

Incidental take authorization (referred to as *take authorization* in this document) will be granted by the U.S. Fish and Wildlife Service (USFWS), and California Department of Fish and Game (CDFG) (collectively, the Wildlife Agencies). The Local Partners are asking the Wildlife Agencies to issue permits that authorize incidental take of covered species. The Plan includes a conservation strategy to compensate for impacts on these covered species. The conservation strategy provides for the conservation and management of covered species and their habitats.

It is anticipated that the Plan will allow issuance of incidental take permits under the ESA and the NCCP Act by the Wildlife Agencies to the local jurisdictions. The Permittees will then be able to use those permits for their own operations, maintenance, and capital projects. The Permittees will also be able to extend the take authorization to private entities conducting activities covered by this Plan and under their jurisdiction<sup>2</sup> (see Chapter 2 for a detailed summary of activities eligible for these permits). The Wildlife Agencies will also provide assurances to the Permittees and Plan participants that no further commitments of funds, land,

<sup>1</sup> *Take* as defined by the ESA means “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct.” *Incidental take* is take that is incidental to, and not intended as part of, an otherwise lawful activity.

<sup>2</sup> Note that the HCP and NCCP permits will only authorize the incidental take of covered species. Most activities will also require additional local authorization (e.g., CEQA), and some activities will also require additional state or federal authorization.

or water will be required to address impacts on covered species beyond that described in the Plan as long as the Permittees are adequately implementing the Plan (see Chapter 10).

The Plan will also be used to comply with Section 7 of the ESA for projects with federal agency involvement. See Section 1.3.1 *Federal and State Endangered Species Laws* for more details.

### 1.1.3 Background

Local Partner agencies in Santa Clara County have until now primarily conducted threatened and endangered species permitting for urban growth, infrastructure development, and operations and maintenance activities with the Wildlife Agencies on a project-by-project basis<sup>3</sup>. In 2001, a USFWS Section 7 biological opinion (U.S. Fish and Wildlife Service 2001) recommended that a regional HCP for all or most of Santa Clara County be developed as a condition for approval of several development and road construction activities; these are listed below.

- U.S. Highway (U.S.) 101 widening (San José to Morgan Hill).
- Bailey Avenue Extension/U.S. 101 interchange.
- U.S. 85/101 South interchange.
- Coyote Valley Research Park.

An HCP was recommended so that local agencies could offset the cumulative and indirect effects of large-scale development and infrastructure projects on federally listed species. Similar recommendations have been made for other northern California counties (e.g., Contra Costa, Solano, Yolo, Sacramento, Yuba, Sutter, and Placer) for their large-scale water and transportation infrastructure projects.

In response to this recommendation, the County, the City of San José, VTA, and SCVWD entered into discussions that led to the signing of a memorandum of understanding (MOU) in June 2004 (City of San José et al. 2004). This MOU stated the signatories' agreement to develop a joint HCP/NCCP and to share in its funding. The MOU also stated that this HCP/NCCP would be a multi-species, multi-habitat plan that would establish a regional reserve system and would address and satisfy immediate and future regulatory compliance needs of the signatories. The regional reserve system would focus on acquisition, preservation, restoration, monitoring, and management of habitat used by the covered species identified in the Plan. Soon after the MOU was signed, these local agencies entered negotiations with CDFG to develop a Planning Agreement, a requirement of the NCCP Act.

---

<sup>3</sup> An important exception is the SCVWD's Stream Maintenance Program permits, described in Chapter 2, Section 2.3.4.

Two new Local Partners, the Cities of Gilroy and Morgan Hill, joined the process in 2005.

All six Local Partners, USFWS, and CDFG signed a Planning Agreement on October 20, 2005 (County of Santa Clara et al. 2005). The purpose of this Planning Agreement was to lay the groundwork for development of an HCP/NCCP. Specifically, the Planning Agreement:

- Defined the signatories' goals and obligations with respect to development of the Plan.
- Created a preliminary description of the geographic scope, natural communities and species, and conservation objectives for the Plan.
- Ensured coordination between the Local Partners and Wildlife Agencies.
- Established concurrent planning for wetlands.
- Established a process for inclusion of scientific input and public participation.

The Planning Agreement defines the Plan as satisfying the requirements for an HCP under Section 10 of the ESA and an NCCP under the state NCCP Act.

The role of the Local Partners is to manage and fund development of the Plan for submission to the Wildlife Agencies. Pursuant to Section 10(a)(1)(B) of the ESA, once approved, the Plan and associated permit will authorize incidental take of federally listed species within the study area. The approved Plan will also serve as an NCCP and, once approved by CDFG, will enable CDFG to authorize take of covered species under Section 2835 of the California Fish and Game Code.

The Santa Clara Valley Open Space Authority (Open Space Authority) is expected to be a key partner during Plan implementation (see Chapter 8).

## 1.2 Scope of the Habitat Plan

This section introduces key elements of the Habitat Plan: covered activities, geographic scope, permit term, and covered species.

### 1.2.1 Covered Activities

A primary goal of this Plan is to protect species and their habitats in order to obtain authorization for incidental take of covered species under the ESA and the NCCP Act for certain types of activities in specific areas of Santa Clara County, in accordance with approved land use plans. *Covered activities* are those projects or ongoing activities that will receive incidental take authorization by the ESA and NCCP permits. Covered activities in the Plan fall into seven general categories.

- Urban development.
- In-stream capital projects.
- In-stream operations and maintenance.
- Rural capital projects outside streams.
- Rural development.
- Rural operation and maintenance of public infrastructure outside streams.
- Conservation strategy implementation (i.e., activities within the lands managed, enhanced, restored, and monitored to conserve the natural resources targeted by this Plan).

For details on the covered activities and the criteria used to select them, see Chapter 2 *Land Use and Covered Activities*.

## 1.2.2 Geographic Scope

The Local Partners began the planning process by defining a broad area—the *study area*—in which all planning would occur for the Plan.

### Study Area

The study area lies within Santa Clara County (**Figures 1-1 and 1-2**)<sup>4</sup>. Santa Clara County has a land area of 835,449 acres; the study area encompasses 519,506 acres, or approximately 62% of the county. The study area was defined as the area in which all covered activities would occur, impacts would be evaluated, and conservation activities would be implemented. The boundary of the study area was based on political, ecological, and hydrologic factors. The study area includes all of the Llagas/Uvas/Pajaro watersheds within Santa Clara County and all of the Coyote Creek watershed except for the Baylands. A large portion of the Guadalupe watershed is also within the study area. The study area also encompasses small areas outside these watersheds, as described below.

The northern edge of the study area is defined by the boundary of Alameda and Santa Clara Counties, excluding the Milpitas City Limits<sup>5</sup> and lands to the north owned by the San Francisco Public Utilities Commission (SFPUC). The SFPUC is preparing an HCP for lands in their Alameda watershed that includes approximately 10,000 acres in Santa Clara County.

<sup>4</sup> As discussed below, California State Parks (State Parks) lands are excluded from the permit area. Because of this exclusion, all of the land cover-related analyses in the Plan are based on the study area less State Parks lands unless otherwise noted. The size of the study area less State Parks lands is 460,205 acres.

<sup>5</sup> For convenience, all of Ed R. Levin County Park is included in the study area, even though a portion of this park is in Milpitas.

Lands in Joseph D. Grant County Park and Mount Madonna County Park outside the Coyote Creek and Llagas/Uvas/Pajaro watersheds are included in the study area, marking the eastern and southwestern boundaries of the study area, respectively. This inclusion allows full coverage of activities in these County parks under the Plan.

Tulare Hill, the Santa Teresa Hills, and the Calero Reservoir area, all within the Guadalupe River watershed, are included in the study area to ensure inclusion of serpentine soils and all occupied and potential habitat for Bay checkerspot butterfly, one of the primary covered species for this Plan.

Almaden Quicksilver County Park is in the study area to ensure inclusion of additional serpentine habitat, which supports a disproportionately high number of covered species, particularly covered plants.

Lands along Los Gatos Creek upstream through Vasona County Park owned by SCVWD and the County of Santa Clara Parks and Recreation Department (County Parks) (County of Santa Clara, Parks and Recreation Department 2003) are included in the study area to allow additional coverage of activities by these agencies.

Almost the entire City of San José lies within the study area. The Baylands and Alviso within San José are not within the study area to exclude current and historic tidally influenced areas. This line was drawn with reference to December 2005 color aerial photographs, historic maps of tidal areas (San Francisco Estuary Institute 2006), and data from the Baylands Ecosystem Goals Project (Goals Project 1999). Within San José, the northern boundary of the study area is the northern edge of the “bufferlands” of the Water Pollution Control Plant facility on Zanker Road.

San José’s Baylands were excluded from the study area to avoid covering species restricted to salt marshes and other saline habitats, which would significantly complicate the Plan. Other substantial planning efforts are underway in the Baylands of Santa Clara County (e.g., South Bay Salt Ponds Restoration Project); this area was excluded to avoid duplicating those efforts. In addition, no impacts are expected to occur to the unique Baylands species from covered activities.

## **Expanded Study Area for Burrowing Owl Conservation**

During Plan development, it became necessary to include conservation actions immediately outside of the study area in order to adequately mitigate and contribute to the recovery of western burrowing owl, one of the covered species. As described in Chapter 5 and in the species account (**Appendix D**), the population of western burrowing owl is declining in the study area. Conservation opportunities in the study area to increase the local population are very limited. After extensive discussions with the Wildlife Agencies and species experts, it became clear that the only way to increase the local population was to provide conservation outside the study area.

To address this need, an *expanded study area for burrowing owl conservation* (expanded study area) was identified in the northern edge of the county in portions of the cities of San José, Santa Clara, Mountain View, Milpitas, and Sunnyvale; in Fremont in Alameda County; and a small portion of San Mateo County (**Figure 1-2**). The expanded study area for burrowing owl conservation that falls outside of the primary Habitat Plan study area is 48,464 acres.

The allowable covered activities in this expanded study area are limited only to conservation actions for western burrowing owl. Coverage for these activities is provided only for this species. Projects and activities of the other jurisdictions, which are not Permittees, are not covered.

## Permit Area

The *permit area* is the area in which the Permittees are requesting take authorization from USFWS and CDFG for activities and projects covered by this Plan. The permit area constitutes those lands within the study area and expanded study area for burrowing owl conservation on which covered activities occur (see Chapter 2 for a description of covered activities). The permit area is the same as the study area except that it excludes Henry W. Coe State Park (**Figure 1-2**). This park was excluded from the permit area because activities within this park are not covered by the Habitat Plan and because it represents such a large portion of the study area. The small portion of Pacheco State Park within the study area is also excluded from the permit area. The permit area is 508,669 acres (519,506 acres in the study area + 48,464 in the expended study area - 58,642 acres of Henry W. Coe State Park within the study area<sup>6</sup> - 659 acres of Pacheco State Park within the study area).

The permit area also includes small, unmapped areas. Land management and monitoring activities may occur outside the mapped study area where a conservation parcel straddles the mapped permit area as long as more than half of each parcel is contained within the permit area. These unmapped areas will not exceed a total of 250 acres<sup>7</sup>.

### 1.2.3 Permit Term

The permit term is the time period in which all covered activities can receive take authorization under the Plan, consistent with the requirements of the Plan. The permit term is also the time in which all conservation actions must be successfully completed to offset the impacts of the covered activities.

<sup>6</sup> The total size of the park is 85,843 acres, of which 27,201 acres occurs outside the study area in Santa Clara and Stanislaus Counties.

<sup>7</sup> Because of their uncertain location and lack of data, the unmapped areas are not included in the total study area or permit area acreage or any calculations of land cover type.

The Local Partners are seeking permits from the Wildlife Agencies with terms of 50 years. Each Permittee will request a permit from each of the two Wildlife Agencies. If approved, each Local Partner would receive a permit from each agency. These permits will be tied to this Plan and to the Implementing Agreement (**Appendix B**). Each permit will be issued to all Permittees collectively. Prior to permit expiration, the Permittees may apply to renew or amend the Plan and its associated permits and authorizations to extend their terms. The permit term of 50 years was selected because it allows for the full and successful implementation of the covered activities (Chapter 2), the conservation strategy (Chapter 5), the monitoring and adaptive management program (Chapter 7), and the funding strategy (Chapter 9). Each of these components is discussed below.

## Time to Implement Covered Activities

A summary of major local planning documents and their respective time horizons is provided in **Table 1-1**. These planning documents have durations between 10 and 50 years, reflecting the time it takes to secure funding and permits and construct the projects identified in the plans. The largest source of covered activities is the urban growth of the three participating cities consistent with their general plans<sup>8</sup> (City of San José 2011; City of Gilroy 2002; City of Morgan Hill 2001) and rural oriented growth in unincorporated Santa Clara County. The Morgan Hill and San José general plans have ultimate build out lines<sup>9</sup> that are assumed to be developed with urban uses by the end of the 50-year permit term and not expand in future General Plan updates. The City of San José General Plan assumes eventual urban development in the Almaden Valley Urban Reserve and Coyote Valley Urban Reserve. Specific plans must first be developed and adopted for each area. The City of Gilroy General Plan addresses growth from 2002 through 2020. If a future Gilroy General Plan update expands the City's urban area, impacts of that expansion to covered species will have to be addressed at that time. Growth in the rural areas of the county is much less constrained geographically than in the cities so it is expected to occur, at a fairly even pace throughout the 50-year permit term, based on trends over the past ten years.

The planning horizon for capital projects is even longer than that of urban development within cities. Timelines for SCVWD's capital projects often extend for decades, so this agency requires a permit term that encompasses the planning horizons of as many of these projects as is feasible. Other covered projects (see Chapter 2) may take several decades to receive the funding needed to implement them (Santa Clara Valley Water District 2000, 2002a, 2002b, 2005a, 2005b). Many public infrastructure projects have a lifespan of 50–100 years. Because much of the public infrastructure in the study area was constructed in the 1940s through the 1960s, local engineers expect most of this infrastructure to need

<sup>8</sup> Any development proposed in future General Plan updates that goes beyond that described in Chapter 2 would not be covered by this Plan; see Chapter 10 for Plan amendment procedures.

<sup>9</sup> Urban Limit Line for Morgan Hill and Greenline for San José.

replacement or major repair in the next 50 years (e.g., all County-maintained bridges are expected to need replacement or major repairs in the next 50 years).

Some covered projects are not expected to be implemented until later in the 50-year permit term. Such projects include the many bridge replacement projects, several flood control and water supply projects, and several road widening projects. A longer permit term is necessary to anticipate and adequately mitigate the impacts of these projects on the covered species.

Ongoing maintenance activities of SCVWD, the County, and participating cities are expected to continue in perpetuity; consequently, take authorization for these activities is needed for as long a period as feasible. As described in Chapter 4, these on-going covered activities are expected to affect the covered species throughout the 50-year permit term. For example, road maintenance performed by the County occurs annually. Maintenance on rural roads is expected to affect habitat for many covered species, including California red-legged frog, California tiger salamander, western burrowing owl, Metcalf canyon jewelflower, most beautiful jewelflower, and Mount Hamilton thistle. Many of these species occur on roadcuts or immediately adjacent to roads in drainages. Similarly, ongoing maintenance by SCVWD covered in this Plan (see Chapter 2) is expected to affect covered species for the duration of the permit term. For example, maintenance of canals has the potential to affect California red-legged frog, western pond turtle, and serpentine plants.

## **Time to Implement, Monitor, and Adjust Conservation Actions**

The length of the permit term also provides adequate time for the assembly of a reserve system and development of a management program on reserve lands. Land will only be acquired from willing sellers. Landowners may not be willing to sell at a reasonable price for many years after the permits are issued. A 50-year permit term provides adequate time for willing landowners to become available and for the land agents of the Plan to negotiate a fair price for the land in fee title or conservation easement (see Chapter 5 for a description of the land acquisition requirements of the Plan and Chapter 8 for a description of the land acquisition process). It may take several years to complete a single land acquisition or purchase a conservation easement. Because 100–200 such transactions will be required to assemble the reserve system, adequate time is needed to ensure this can happen before the end of the permit term. A permit term of 50 years also allows the monitoring and adaptive management programs to become well established so that they will continue in perpetuity successfully. As described in Chapter 7, the monitoring and adaptive management program will go through three distinct phases: data inventory, targeted studies, and long-term monitoring. Each phase will take many years to complete successfully<sup>10</sup>.

<sup>10</sup> Many regional HCPs and NCCPs approved in southern California over 10 years ago are still developing their monitoring programs, demonstrating that it takes decades to develop and implement a successful monitoring program on such a large scale.

One type of monitoring, called “status and trend monitoring”, will track long-term trajectories of species populations and other physical and biological conditions in the study area. A permit term of 50 years will provide adequate time to collect enough trend data for all of the covered species; if management responses are necessary, the permit term will also allow sufficient time to adjust management. Monitoring the success of restoration actions (described in Chapter 5) is expected to take 5–10 years for each restoration project. Most restoration actions cannot be initiated until land is acquired for the reserve system. A permit term of 50 years is necessary to allow enough time to complete land acquisition with at least 5–10 years remaining on the permit in which to successfully initiate or complete (and possibly remediate if necessary) all restoration actions. The Permittees have committed to acquiring all land for the Plan by Year 45 and initiating all restoration projects by Year 40 (see Chapter 5 for details). Therefore, a 50-year permit term is necessary to complete these actions and to leave sufficient time for monitoring before the permit term ends.

A successful program for management, monitoring, and adaptive management is essential to the success of the reserve system after the permit term. The Permittees will be obligated during the permit term to address changes in circumstances foreseen by the Plan (see Chapter 10) and to remediate the conservation areas affected by these changes. A longer permit term is more likely to encompass a changed circumstance that will require a remedial action.

## Time to Secure Adequate Funding

A 50-year permit term allows sufficient time to generate the necessary funding for Plan implementation. As described in Chapter 9, the Plan will be funded by a wide variety of local, state, and federal sources. Some of these sources will not be available for 10–30 years or more. To take advantage of these funding sources, therefore, the permit term must be at least 40 years.

Funding is also needed during the permit term to generate the necessary funds for management and monitoring after the permit expires (e.g., an endowment). In Chapter 9, the Plan describes how this will be accomplished and by when. The permit term must therefore allow sufficient time to accumulate the long-term funding.

## Conclusions

Based on the implementation horizon for covered projects, the ongoing regulatory requirement of operation and maintenance activities, the need to acquire lands and develop a successful reserve system, and the need for adequate funding, the Local Partners have determined that a 50-year permit term will best address regulatory and biological considerations. In summary, the 50-year permit term provides sufficient time to accomplish the following critical elements of the Plan.

- Fully implement the current general plans of the cities and the County.

- Fully implement the Permittees' capital projects that are covered by the Plan.
- Implement the Permittees' ongoing activities as long as is feasible.
- Allow sufficient time to assemble the Plan reserve system from willing sellers and partnerships with local agencies and private landowners.
- Secure all necessary funding for Plan implementation during the permit term and secure funds during the permit term to generate funding for the Plan in perpetuity.
- Develop an effective adaptive management program that will be implemented in perpetuity, given the current uncertainties in knowledge about the ecology of covered species and responses to resource management.
- Provide sufficient incentive for the Local Partners to commit the substantial resources necessary to complete the Habitat Plan (i.e., the permit term covers enough projects and activities to make the large up-front investment in the Habitat Plan cost effective).

Take authorization for all covered activities, including covered operations and maintenance activities, will expire at the end of the permit term, unless the permit is renewed or replaced. Near the end of the permit term, the Permittees will determine whether to extend the term of the permit through the formal amendment process described in Chapter 10.

## 1.2.4 Covered Species

As required by the NCCP Act, this Plan will protect native biological diversity, habitat for native species, natural communities, and local ecosystems. This broad scope will conserve a wide range of natural resources including native species that are common or rare. However, the permits issued by the Wildlife Agencies will name specific species that are either currently listed as threatened or endangered or that may become listed during the permit term.

This Plan addresses 18 listed and nonlisted species (**Table 1-2**): nine wildlife species and nine plant species. These covered species are expected to be named on the ESA and NCCP Act permits. In exchange, the Plan will provide long-term conservation and management of these species. The 18 covered species were identified on the basis of an initial assessment of the effect of covered activities and conservation measures on 148 species that are listed or that could become listed during the permit term in the study area.

The Plan includes conservation measures to protect all 18 covered species, whether or not they are currently listed. Accordingly, any nonlisted species addressed by the Plan's conservation strategy will not require additional conservation within the study area should that species become listed during the permit term. See *Regulatory Setting* below for a discussion of why plants are included as covered species.

During Plan development, coverage for fish species was sought from the National Marine Fisheries Service (NMFS) and CDFG for south central California coast steelhead (*Oncorhynchus mykiss*), central California coast steelhead (*Oncorhynchus mykiss*), and Central Valley fall-run Chinook salmon (*Oncorhynchus tshawytscha*). Coverage was also sought from USFWS and CDFG for Pacific lamprey (*Lampetra tridentata*). To provide this coverage, the Permittees worked closely with these agencies to develop an aquatic conservation strategy for these fish that would meet their regulatory standards. A draft aquatic conservation strategy for the covered fish was included in the second administrative draft Habitat Plan released in June 2009. However, after extensive discussions, it was determined that coverage for fish species should be obtained through a separate process in order to allow the Plan to be completed within the desired timeframe. Thus, south central California coast steelhead, central California coast steelhead, Central Valley fall-run Chinook salmon, and Pacific lamprey are not covered by the Habitat Plan. Coverage for these species in the Guadalupe River and Coyote Creek watersheds will be provided, in part, by the Three Creeks HCP being prepared by SCVWD (see Chapter 2 for a discussion of this HCP). Coverage for these species in the Pajaro River watershed will need to be provided through a separate conservation plan or an amendment to this Habitat Plan (see Chapter 10 for the amendment process). NMFS, USFWS, and CDFG have committed to supporting the Local Partners in the development and eventual permitting of this separate strategy.

## Species Evaluation

To determine which species would be covered by the Plan, a comprehensive list of 148 special-status species that occur or may occur in the study area was compiled (**Appendix C**). This list was developed by reviewing the following sources.

- California Natural Diversity Database (CNDDB) (2008).
- California Native Plant Society (CNPS) (2007) *Inventory of Rare and Endangered Vascular Plants of California*.
- CDFG lists of Special Animals and Special Plants (California Department of Fish and Game 2003, 2006, 2007).
- An animal species list obtained from the USFWS website for Santa Clara County (U.S. Fish and Wildlife Service 2006).
- Personal communication with local experts including Wildlife Agency staff; SCVWD biologists; representatives of local environmental groups including CNPS Santa Clara Valley Chapter, Santa Clara Valley Chapter of the Audubon Society, and Streams for Tomorrow; and members of the Habitat Plan Science Advisors.

## Definition of Special-Status Species

*Special-status species* are defined as plants and animals that are legally protected under ESA, CESA, or other regulations, and species that are considered sufficiently rare by the scientific community to qualify for such listing.

Special-status plants are species with one or more of the following characteristics.

- Listed or proposed for listing as threatened or endangered under ESA (50 Code of Federal Regulations [CFR] 17.12 [listed plants] and various notices in the Federal Register [FR] [proposed species]).
- Candidates for possible future listing as threatened or endangered under the ESA (70 FR 24870–24934, May 11, 2005).
- Listed or candidates for listing by the State of California as threatened or endangered under CESA (14 California Code of Regulations [CCR] 670.5).
- Listed as rare under the California Native Plant Protection Act (California Fish and Game Code Section 1900 et seq.).
- Determined to meet the definitions of rare or endangered under CEQA (State CEQA Guidelines, Section 15380).
- Considered by CNPS to be “rare, threatened or endangered in California” (Lists 1B and 2 in California Native Plant Society 2007) or vascular plants, bryophytes, and lichens listed as having special status by CDFG (California Department of Fish and Game 2007).
- Listed by CNPS as plants about which more information is needed to determine their status and plants of limited distribution (Lists 3 and 4 in California Native Plant Society 2007) that may be included on the basis of local significance or recent biological information.

Special-status animals are species with one or more of the following characteristics.

- Listed or proposed for listing as threatened or endangered under the ESA (50 CFR 17.11 [listed animals] and various notices in the FR [proposed species]).
- Candidates for possible future listing as threatened or endangered under the ESA (70 FR 24870–24934, May 11, 2005).
- Determined to meet the definitions of rare or endangered under CEQA (State CEQA Guidelines, Section 15380).
- Listed or candidates for listing by the State of California as threatened or endangered under CESA (14 CCR 670.5).
- Wildlife species of special concern to CDFG (California Department of Fish and Game 2003).

- Fully protected species under the California Fish and Game Code Section 3511(birds), Section 4700 (mammals), Section 5515 (fish), and Section 5050 (reptiles and amphibians).
- Species with no formal special status but thought by experts to be rare or in serious decline and to warrant special status based on recent information.

## Covered Species Criteria

For each special-status species with potential to occur in the study area (**Appendix C**), information was gathered on its status, population trends, distribution, threats, conservation, and management efforts. The following criteria were then applied to each species to determine whether it would be covered (i.e., included in the final permits). To be covered, a species had to meet all four of the following criteria.

### Range

The species is known to occur or is likely to occur within the Plan study area, based on credible evidence, or the species is not currently known in the study area but is expected to occur in the study area during the permit term (e.g., through range expansion or reintroduction to historic range).

### Status

The species meets at least one of the following statutory criteria.

- Listed under the ESA as threatened or endangered, or proposed for listing.
- Listed under CESA as threatened or endangered or a candidate for such listing.
- Listed under the Native Plant Protection Act as rare.
- Expected to be listed under ESA or CESA within the permit term (assumed to be 50 years). Potential for listing during the permit term is based on current listing status, consultation with experts and Wildlife Agency staff, evaluation of species population trends and threats, and best professional judgment of the biologists working on the Plan.

### Impact

The species or its habitat would be adversely affected by covered activities or projects that may result in take of the species.

## Data

Sufficient data on the species' life history, habitat requirements, and occurrence in the study area are available to adequately evaluate impacts on the species and to develop conservation measures to mitigate these impacts to levels specified by regulatory standards.

Species proposed for coverage in the Plan were limited to those species for which impacts from covered activities were likely. However, it is important to note that many other special-status species and common species are expected to benefit from the conservation strategy of this Plan, as described in Chapter 5.

### 1.2.5 Relationship to the Proposed Three Creeks Habitat Conservation Plan

SCVWD is developing the Three Creeks Habitat Conservation Plan (Three Creeks HCP) to protect and enhance habitats for a suite of aquatic species and provide conservation for species impacted by SCVWD's on-going water supply operations in the northern Santa Clara Valley.

The geographic area of the proposed Three Creeks HCP includes the following.

- Coyote Watershed in the eastern portion of the County. Sixteen major creeks drain this 322-square-mile area. The county's largest watershed, it extends from the urbanized valley floor upward to the natural areas of the Mt. Hamilton range. Coyote Creek, its main waterway, is the longest creek in the county.
- Guadalupe Watershed in the east-central part of the County. This 170-square-mile area drains to the Guadalupe River and its tributaries through downtown San José. SCVWD has facilities on four major tributaries: Calero Creek, Alamitos Creek, Guadalupe Creek, and Los Gatos Creek. The Guadalupe River Watershed drains both the Mt. Hamilton Range and the Santa Cruz Mountains Range (Los Gatos Creek).
- Stevens Creek Watershed in the southwest portion of the County. This watershed is part of the Lower Peninsula Watershed, a 98-square-mile area whose many small-creek watersheds feed the tidal wetlands along the San Francisco Bay's southwest shoreline. Stevens Creek has one of the last remaining viable steelhead trout runs in the County.

The geographic area of the proposed Three Creeks HCP partially overlaps with the Habitat Plan study area. The Three Creeks HCP includes the Stevens Creek, Guadalupe, and Coyote watersheds but does not include the Pajaro/Uvas/Llagas watersheds. The Plan study area does not include the Stevens Creek watershed and the Los Gatos Creek portion of the Guadalupe watershed. See **Figure 1-3** for a map of the Three Creeks HCP program area in relation to the Habitat Plan study area.

The proposed Three Creeks HCP covers implementation of capital projects and operations and maintenance activities within its study area related to water supply. The Three Creeks HCP is a standalone document; however, the activities described in Chapter 2 of this Plan that occur in the Three Creeks HCP study area (Guadalupe Creek, Alamitos Creek, Calero Creek, the Guadalupe River, Coyote Creek, and Penitencia Creek) are covered activities under both the Three Creeks HCP and the Habitat Plan. Covered activities described in this Plan that occur in the Uvas/Llagas watersheds are only covered by this Plan. Three Creeks HCP activities within Los Gatos Creek will be covered by this Plan at and below Vasona Lake. The Habitat Plan does not include Stevens Creek or Los Gatos Creek above Vasona Lake.

In addition to the water supply activities, the proposed Three Creeks HCP contains a Conservation Program targeted at the conservation of listed fish species. Some of the conservation actions described in the Three Creeks HCP may have adverse affects on semi-aquatic species covered by this Plan, including the California tiger salamander, California red-legged frog, and western pond turtle. Therefore, this Plan covers the activities described in the Three Creeks HCP Conservation Program for potential impacts to species covered by this Plan. The Three Creeks HCP Conservation Plan is described in Chapter 2.

Under the proposed Three Creeks HCP, SCVWD will request incidental take permits from USFWS and CDFG (through a Fish and Game Code Section 2080.1 concurrence finding or a 2081 incidental take permit) for the species and geographic areas unique to the Three Creeks HCP.

## 1.3 Regulatory Setting

The Plan is designed primarily to comply with the ESA, CESA, and the NCCP Act. The Plan is also consistent with other federal and state wildlife and related laws and regulations, listed here and described in greater detail below.

- Migratory Bird Treaty Act.
- Bald Eagle and Golden Eagle Protection Act.
- California Fish and Game Code Sections 3511, 4700, 5050, 5515 (fully protected species).
- California Fish and Game Code Section 3503 (bird nests).
- California Fish and Game Code Section 3503.5 (birds of prey).
- National Environmental Policy Act of 1969.
- California Environmental Quality Act of 1970.
- Clean Water Act of 1972 Sections 401 and 404.
- Porter-Cologne Water Quality Control Act.
- California Fish and Game Code Sections 1600–1616 (Lake or Streambed Alteration Agreement).
- National Historic Preservation Act.

## 1.3.1 Federal and State Endangered Species Laws

### Federal Endangered Species Act

USFWS and NMFS administer the ESA. ESA requires USFWS and NMFS to maintain lists of threatened and endangered species and affords substantial protection to listed species. NMFS's jurisdiction under ESA is limited to the protection of marine mammals, marine fishes, and anadromous fishes<sup>11</sup>; all other species are subject to USFWS jurisdiction.

USFWS and NMFS can list species as either *endangered* or *threatened*. An *endangered* species is at risk of extinction throughout all or a significant portion of its range (ESA Section 3[6]). A *threatened* species is likely to become endangered within the foreseeable future (ESA Section 3[19]). Section 9 of the ESA prohibits the take of any fish or wildlife species listed under ESA as endangered or threatened<sup>12</sup>. *Take*, as defined by ESA, means “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct.” *Harm* is defined as “any act that kills or injures the species, including significant habitat modification or degradation where it actually kills or injures wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering” (50 CFR 17.3). Section 9 prohibits the “removal or reduction to possession” of any listed plant species “under federal jurisdiction” (i.e., on federal land, where federal funding is provided, or where federal authorization is required). Even though under ESA there is no prohibition for take of plants on nonfederal lands, this Plan includes many covered plants. Some plants are covered in order to meet regulatory obligations under ESA Section 7 and to comply with CESA. Incidental take authorization is also requested for plants to provide no-surprises assurances for these species (see Chapter 10 *Assurances*).

The ESA includes mechanisms that provide exceptions to the Section 9 take prohibitions. These are addressed in Section 7 for federal actions and Section 10 for nonfederal actions.

### Section 7

Section 7 of the ESA requires all federal agencies to ensure that any action they authorize, fund, or carry out is not likely to jeopardize the continued existence of any listed species or result in the destruction or adverse modification of habitat critical to such species' survival. To ensure that its actions do not result in

<sup>11</sup> *Anadromous fishes* are fish that spend part of their life cycle in the ocean and part in fresh water. NMFS has jurisdiction over anadromous fish that spend the majority of their life cycle in the ocean.

<sup>12</sup> The protection of threatened species under Section 9 is discretionary through a rule issued under Section 4(d) of the ESA. Until a “4(d) rule” is issued by NMFS, threatened anadromous fish or marine species are not protected by the ESA. By regulation, the USFWS automatically affords Section 9 protections to threatened species at the time of listing. These protections can later be modified by USFWS through a 4(d) rule.

jeopardy to listed species or in the adverse modification of critical habitat<sup>13</sup>, each federal agency must consult with USFWS or NMFS—or both—regarding federal agency actions that may affect listed species. The issuance of permits for this Plan is a federal action that triggers a Section 7 consultation. Consultation begins when the federal agency submits a written request for initiation to USFWS or NMFS, along with the agency’s biological assessment of its proposed action, and when USFWS or NMFS accepts that biological assessment as complete. If USFWS or NMFS concludes that the action is not likely to adversely affect a listed species, the action may be conducted without further review under ESA. Otherwise, USFWS or NMFS must prepare a written biological opinion describing how the agency’s action will affect the listed species and its critical habitat. For this Plan, the USFWS will consult internally (with itself) to comply with Section 7 of the ESA.

If the biological opinion concludes that the proposed action would jeopardize the continued existence of a listed species or adversely modify its critical habitat, the opinion will suggest “reasonable and prudent alternatives” that would avoid that result. If the biological opinion concludes that the proposed action would take a listed species but would not jeopardize its continued existence, the biological opinion will include an *incidental take statement*. *Incidental take* is take that is “incidental to, and not intended as part of, an otherwise lawful activity” (64 CFR 60728). The incidental take statement specifies an amount of take that is allowed to occur as a result of the action and may require reasonable and prudent measures to minimize the impact of the take.

Any project with a federal lead agency or federal involvement (e.g., a federal permit, federal funding, or a project on federal land) must obtain their take authorization through Section 7 rather than Section 10 and an HCP. This means that projects with federal involvement cannot directly utilize an approved HCP for their take authorization. However, if the applicant complies with the conservation measures in this Plan, the Section 7 consultation process is expected to be greatly streamlined. Therefore, the covered activities described in Chapter 2 include projects or activities that may need to obtain their take authorization through Section 7. Unless otherwise required by law or regulation, USFWS will ensure that a biological opinion for a project with a federal lead agency that is addressed by the Plan is consistent with the biological opinion for the Habitat Plan. USFWS will not impose measures on applicants for coverage under the Plan in excess of those that have been or will be required by the Implementing Agreement<sup>14</sup>, the Plan, and the permits, unless otherwise required by law or regulation. Federal agencies cannot receive the regulatory assurances available under Section 10 of the ESA.

<sup>13</sup> *Critical habitat* is defined as specific geographic areas, whether occupied by listed species or not, that are determined to be essential for the conservation and management of listed species, and that have been formally described in the Federal Register.

<sup>14</sup> The Implementing Agreement is a legal document, signed by all parties, that identifies roles and responsibilities of all parties, including the Permittees and the Wildlife Agencies. The agreement typically incorporates actions from the conservation plan that are agreed to by all parties. See Appendix B for the Implementing Agreement for this Plan.

## Section 10

Until 1982, state, local, and private entities had no means to acquire incidental take authorization as could federal agencies under Section 7. Private landowners and local and state agencies risked direct violation of the ESA no matter how carefully their projects were implemented. This statutory dilemma led Congress to amend Section 10 of the ESA in 1982 to authorize the issuance of an incidental take permit to nonfederal project proponents upon completion of an approved conservation plan. The term *conservation plan* has evolved into *habitat conservation plan*.

In cases where federal land, funding, or authorization is not required for an action by a nonfederal entity, the take of listed fish and wildlife species can be permitted by USFWS and/or NMFS through the Section 10 process. Private landowners, corporations, state agencies, local agencies, and other nonfederal entities must obtain a Section 10(a)(1)(B) *incidental take permit* for take of federally listed fish and wildlife species “that is incidental to, but not the purpose of, otherwise lawful activities.”

The take prohibition for listed plants is more limited than for listed fish and wildlife. Under Section 9(a)(2)(B) of the ESA, endangered plants are protected from “removal, reduction to possession, and malicious damage or destruction” in areas that are under federal jurisdiction. Section 9(a)(2)(B) of the ESA also provides protection to plants from removal, cutting, digging up, damage, or destruction where the action takes place in violation of any state law or regulation or in violation of a state criminal trespass law. Thus, the ESA does not prohibit the incidental take of federally listed plants on private or other nonfederal lands unless the action requires federal authorization or is in violation of state law. Thus, Section 10 incidental take permits are only required for wildlife and fish species. However, the Section 7(a)(2) prohibition against jeopardy applies to plants, and issuance of a Section 10(a)(1)(B) incidental take permit cannot result in jeopardy to a listed plant species.

The HCP must specify the following mandatory elements.

- The impact that will likely result from the taking of covered species.
- The steps the applicant will take to monitor, minimize, and mitigate such impacts to the maximum extent practicable.
- The funding that will be available to implement such steps.
- The procedures to be used to deal with unforeseen circumstances<sup>15</sup>.
- The alternative actions to such taking the applicant considered and the reasons why such alternatives are not proposed to be utilized.

<sup>15</sup> *Unforeseen circumstances* are changes in circumstances affecting a covered species or geographic area covered by the HCP that could not reasonably have been anticipated by the plan developers, and that result in a substantial and adverse change in the status of a covered species.

- Such other measures that the Director [of the Department of Interior or Commerce] may require as being necessary or appropriate for purposes of the plan (50 CFR 17.22(b)).

The Santa Clara Valley Habitat Plan is intended to satisfy these requirements.

To receive an incidental take permit, Section 10(a)(2)(B) of the ESA requires that the following criteria be met.

- The taking will be incidental to otherwise lawful activities.
- The applicant will, to the maximum extent practicable, minimize and mitigate the impacts of such taking.
- The applicant will ensure adequate funding for the HCP and procedures to deal with unforeseen circumstances.
- The taking will not appreciably reduce the likelihood of survival and recovery of the species in the wild.
- The applicant will ensure that other measures that the Services [USFWS and NMFS] may require as being necessary or appropriate will be provided.
- The Services have received such other assurances as may be required that the HCP will be implemented.

Prior to the approval of an HCP, USFWS is required to undertake an internal Section 7 consultation<sup>16</sup> because issuance of an incidental take permit is a federal action. (See the discussion of ESA Section 7, above.) Elements specific to the Section 7 process that are not required under the Section 10 process (e.g., analysis of impacts on designated critical habitat, analysis of impacts on listed plant species, and analysis of indirect and cumulative impacts on listed species) are included in this Plan to meet the requirements of Section 7.

## California Endangered Species Act

CESA prohibits take of wildlife and plants listed as threatened or endangered by the California Fish and Game Commission. *Take* is defined under the California Fish and Game Code (more narrowly than under ESA) as any action or attempt to “hunt, pursue, catch, capture, or kill.” Therefore, take under CESA does not include “the taking of habitat alone or the impacts of the taking”<sup>17</sup>. Rather, the courts have affirmed that under CESA, “taking involves mortality.”

Like ESA, CESA allows exceptions to the prohibition for take that occurs during otherwise lawful activities. The requirements of an application for incidental take under CESA are described in Section 2081 of the California Fish and Game Code. Incidental take of state-listed species may be authorized if an applicant submits an approved plan that minimizes and “fully mitigates” the impacts of this take.

<sup>16</sup> When USFWS issues a permit, they will consult with itself and NMFS, if necessary.

<sup>17</sup> *Environmental Council of Sacramento v. City of Sacramento*, 142 Cal. App. 4th 1018 (2006).

## Natural Community Conservation Planning Act

In 1991, California's NCCP Act (California Fish and Game Code, Section 2800 et seq.) was enacted to implement broad-based planning that balances appropriate development and growth with conservation of wildlife and habitat. Pursuant to the NCCP Act, local, state, and federal agencies are encouraged to prepare NCCPs to provide comprehensive management and conservation of multiple species and their habitats under a single plan, rather than through preparation of numerous individual plans on a project-by-project basis. The NCCP Act is broader in its orientation and objectives than are ESA and CESA, and preparation of an NCCP is voluntary. The primary objective of the NCCP program is to conserve natural communities at the ecosystem scale while accommodating compatible land use. To be approved by CDFG, an NCCP must provide for the conservation of species and protection and management of natural communities in perpetuity within the area covered by permits. *Conservation* is defined by the NCCP Act and the California Fish and Game Code as actions that result in the delisting of state-listed species. Thus, NCCPs must contribute to the recovery of listed species or prevent the listing of nonlisted species rather than just mitigate the effects of covered activities. This recovery standard is one of the major differences between an NCCP and an HCP prepared to satisfy ESA or CESA.

The 1991 NCCP Act was replaced with a substantially revised and expanded NCCP Act in 2002. The revised NCCP Act established new standards and guidance on many facets of the program, including scientific information, public participation, biological goals, interim project review, and approval criteria. The new NCCP Act took effect on January 1, 2003. To approve an NCCP under the new NCCP Act, CDFG must make a series of findings.

- The Plan must be consistent with the Planning Agreement.
- The Plan must provide for the conservation and management of the covered species (*conservation* is defined to mean that the Plan must contribute to species recovery).
- The Plan must protect habitat, natural communities, and species diversity on the landscape level (definitions of these and other NCCP terms are provided in Chapter 3 and **Appendix A**).
- The Plan must conserve the ecological integrity of large habitat blocks, ecosystem function, and biodiversity.
- The Plan must support sustainable populations of covered species.
- The Plan must provide a range of environmental gradients and habitat diversity to support shifting species distributions.
- The Plan must sustain movement of species among reserves.
- Mitigation and conservation must be roughly proportional to impacts in timing and extent.
- Funding for conservation, monitoring, and adaptive management must be adequately assured.

The Santa Clara Valley Habitat Plan is intended to comply with the NCCP Act to conserve the covered species and ecosystems of a significant part of Santa Clara County and to provide authorization for take of covered species in accordance with Section 2835 of the California Fish and Game Code. **Table 1-3** provides a “checklist” of NCCP findings that CDFG must make to issue its NCCP permit along with the locations in the document where those findings are supported.

## 1.3.2 Other Federal and State Wildlife Laws and Regulations

### Migratory Bird Treaty Act

The Migratory Bird Treaty Act of 1918, as amended (MBTA), implements various treaties and conventions between the U.S. and Canada, Japan, Mexico, and the former Soviet Union for the protection of migratory birds. Under the MBTA, taking, killing, or possessing migratory birds is unlawful, as is taking of any parts, nests, or eggs of such birds (16 U.S. Government Code [USC] 703). *Take* is defined more narrowly under the MBTA than under ESA and includes only the death or injury of individuals of a migratory bird species or their eggs. As such, *take* under the MBTA does not include the concepts of harm and harassment as defined under ESA. The MBTA defines migratory birds broadly; all covered birds in this Plan are considered migratory birds under the MBTA.

USFWS provides guidance regarding take of federally listed migratory birds (Appendix 5 in the HCP Handbook [U.S. Fish and Wildlife Service and National Marine Fisheries Service 1996]). According to these guidelines, an incidental take permit can function as a Special Purpose Permit under the MBTA (50 CFR 21.27) for the take of all ESA-listed covered species in the amount and/or number and subject to the terms and conditions specified in an HCP. Any such take will not be in violation of the MBTA (16 USC 703-12). The following covered species are protected by the MBTA.

- Western burrowing owl.
- Least Bell’s vireo.
- Tricolored blackbird.

Of these, only least Bell’s vireo is currently listed under ESA. Accordingly, once issued, the incidental take permit will automatically function as a Special Purpose Permit under the MBTA, as specified under 50 CFR Sec. 21.27, for least Bell’s vireo for a 3-year term subject to renewal by the Permittees. Should any other of the covered birds become listed under ESA during the permit term, the ESA permit would also constitute a Special Purpose Permit under the MBTA for that species for a 3-year term as specified under 50 CFR 21.27 subject to renewal by the Permittees.

Nonlisted covered species as well as other migratory birds not covered by the permit will benefit from seasonal restrictions on construction and other

conservation measures described in this Plan. The creation of the Reserve System and subsequent restoration and management will also be a significant “benefit to the migratory bird resource” as required by the Special Purpose Permit. Compliance with the conditions on covered activities described in Chapter 6 are consistent with the requirements of the MBTA for the covered migratory birds. It will be the responsibility of individual project applicants to fully comply with the MBTA for non-covered migratory birds.

## Bald and Golden Eagle Protection Act

The Bald and Golden Eagle Protection Act (Eagle Act) prohibits the taking or possession of and commerce in bald and golden eagles with limited exceptions. Under the Eagle Act, it is a violation to “take, possess, sell, purchase, barter, offer to sell, transport, export or import, at any time or in any manner, any bald eagle commonly known as the American eagle, or golden eagle, alive or dead, or any part, nest, or egg, thereof.” *Take* is defined to include pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, destroy, molest, and disturb. *Disturb* is further defined in 50 CFR Part 22.3 as “to agitate or bother a bald or golden eagle to a degree that causes, or is likely to cause, based on the best scientific information available (1) injury to an eagle, (2) a decrease in its productivity, by substantially interfering with normal breeding, feeding, or sheltering behavior, or (3) nest abandonment, by substantially interfering with normal breeding, feeding, or sheltering behavior.”

Recent revisions to the Eagle Act authorizes take of bald eagles and golden eagles under the following conditions: (1) where the take is compatible with the preservation of the bald eagle and golden eagle, (2) is necessary to protect an interest in a particular locality, (3) is associated with but not the purpose of an otherwise lawful activity, and (4) for individual instances of take the take cannot be avoided, or (5) for programmatic take the take is unavoidable even though advanced conservation practices are being implemented (50 CFR 22.26). Permits issued under this regulation usually authorize disturbance only; however, in limited cases a permit may authorize lethal take that results from but is not the purpose of an otherwise lawful activity.

Bald and golden eagles are not covered species in this Plan.

## California Fully Protected Species

In the 1960s, before CESA was enacted, the California legislature identified specific species for protection under the California Fish and Game Code. These *fully protected* species may not be taken or possessed at any time, and no licenses or permits may be issued for their take except for collecting these species for necessary scientific research and relocation of bird species for the protection of livestock. Fully protected species are described in Sections 3511 (birds), 4700 (mammals), 5050 (reptiles and amphibians), and 5515 (fish) of the California Fish and Game Code. These protections state that “...no provision of

this code or any other law shall be construed to authorize the issuance of permits or licenses to take any fully protected [bird], [mammal], [reptile or amphibian], [fish].” This Plan includes conservation measures to avoid taking fully protected species as defined by the California Fish and Game Code<sup>18</sup>. Fully protected species expected to occur in the study area include, but are not restricted to, those listed below.

- Golden eagle.
- American peregrine falcon.
- Southern bald eagle.
- White-tailed kite.
- California condor.
- Ring-tailed cat (= ringtail).

## California Fish and Game Code 3503 (Bird Nests)

Section 3503 of the California Fish and Game Code makes it “unlawful to take, possess, or needlessly destroy the nests or eggs of any bird, except as otherwise provided by this code or any regulation made pursuant thereto.” Therefore, CDFG may issue permits authorizing take. The Plan contains conservation measures to avoid and minimize such take to the maximum extent practicable in order to comply with Section 3503. However, some take to covered birds may still occur; the NCCP permit will serve as the authorization for take nests or eggs of covered birds pursuant to Section 3503.

## California Fish and Game Code 3503.5 (Birds of Prey)

Section 3503.5 of the California Fish and Game Code prohibits the take, possession, or destruction of any birds of prey or their nests or eggs “except as otherwise provided by this code or any regulation adopted pursuant thereto.” CDFG may issue permits authorizing take of birds of prey or their nests or eggs pursuant to CESA or the NCCP Act. The only bird of prey covered by the Plan is the western burrowing owl (**Table 1-2**). The Plan contains conservation measures to avoid and minimize take of western burrowing owl in order to comply with Section 3503.5. The NCCP permit will serve as the authorization for take of birds, eggs, or nests of western burrowing owl that cannot be avoided pursuant to Section 3503.5.

---

<sup>18</sup> Recent legislation allows NCCPs to provide take authorization for fully protected species covered by an NCCP. Because no fully protected species is covered by this Plan, take of fully protected species must be avoided.

### 1.3.3 National Environmental Policy Act

NEPA requires federal agencies to include in their decision-making process appropriate and careful consideration of all environmental effects of a proposed action and of possible alternatives. Documentation of the environmental impact analysis and efforts to avoid or minimize the adverse effects of proposed actions must be made available for public notice and review. This analysis is documented in either an environmental assessment or an environmental impact statement (EIS). Project proponents must disclose in these documents whether their proposed action will adversely affect the human or natural environment. NEPA's requirements are primarily procedural rather than substantive in that NEPA requires disclosure of environmental effects and mitigation possibilities but includes no requirement to mitigate.

The issuance by USFWS of an incidental take permit under Section 10 of the ESA constitutes a federal action. Therefore, USFWS must comply with NEPA. To satisfy NEPA requirements, USFWS released a draft EIS in mid-December of 2010 for a 90-day comment period that closed in March 2011. The draft EIS accompanied the draft Habitat Plan.

### 1.3.4 California Environmental Quality Act

CEQA is similar to but more extensive than NEPA in that it requires that significant environmental impacts of proposed projects be reduced to a less-than-significant level through adoption of feasible avoidance, minimization, or mitigation measures unless overriding considerations are identified and documented that make the mitigation measures or alternatives infeasible. CEQA applies to certain activities in California undertaken by either a public agency or a private entity that must receive some discretionary approval from a California government agency. In issuing the NCCP Act permit, CDFG must comply with CEQA. Similarly, the action of the Local Partners in adopting the Plan is subject to CEQA compliance. The County of Santa Clara is serving as the lead agency under CEQA. To comply with CEQA, the Local Partners released a draft joint environmental impact statement/ environmental impact report (EIS/EIR) in mid-December of 2010. The public comment period on the draft EIS/EIR closed in March 2011. The draft EIS/EIR accompanied the draft Habitat Plan.

The final EIS/EIR prepared for the Habitat Plan is intended to provide programmatic compliance with CEQA for all activities covered by this Plan. Future projects that receive take coverage under the Plan must also comply with CEQA at the project level through their local jurisdiction. It is expected that the conservation provided in this Plan will be sufficient to meet all CEQA mitigation standards for impacts on the special-status species and natural communities that are covered in this Plan. However, because circumstances may change, full CEQA coverage through the EIS/EIR prepared for the Habitat Plan cannot be guaranteed. Barring major changes, it is expected that future CEQA documents for activities that receive take coverage under this Plan will incorporate the conservation measures in this Plan by reference to comply with CEQA for the

covered species and natural communities addressed in this Plan. The Plan implements a conservation strategy designed to achieve a comprehensive set of biological goals and objectives. Furthermore, as an NCCP, the Plan provides for broad-based planning to preserve natural communities at the ecosystem scale.

Many of the conservation measures in the Plan will also benefit other special-status species (i.e., species not covered by the Plan); such measures may be sufficient to meet CEQA standards for these other species as well.

### **1.3.5 Federal and State Wetland Laws and Regulations**

#### **Clean Water Act Section 404**

The Clean Water Act is the primary federal law that protects the physical, chemical, and biological integrity of the nation's waters, including lakes, rivers, wetlands, and coastal waters. Programs conducted under the Clean Water Act are directed at both point source pollution (e.g., waste discharged from outfalls and filling of waters) and nonpoint source pollution (e.g., runoff from parking lots). Under the Clean Water Act, the U.S. Environmental Protection Agency (EPA) and state agencies set effluent limitations and issue permits under Clean Water Act Section 402 governing point-source discharges of wastes to waters. The U.S. Army Corps of Engineers (Corps), applying its regulations under guidelines issued by EPA, issues permits under Clean Water Act Section 404 governing under what circumstances dredged or fill material may be discharged to waters. These Section 402 and 404 permits are the primary regulatory tools of the Clean Water Act. EPA has oversight over all Clean Water Act permits issued by the Corps.

The Corps issues two types of permits under Section 404: general permits (either nationwide permits or regional permits) and standard permits (either letters of permission or individual permits). General permits are issued by the Corps to streamline the Section 404 process for nationwide, statewide, or regional activities that have minimal direct or cumulative environmental impacts on the aquatic environment. Standard permits are issued for activities that do not qualify for a general permit (i.e., that may have more than a minimal adverse environmental impact).

In early 2012, the Local Partners began pursuing a Regional General Permit (RGP) for the Habitat Plan from the San Francisco District of the Corps for activities covered by the Habitat Plan that also dredge or fill wetlands and other waters of the U.S. The purpose of the RGP would be to provide a simplified and streamlined means for the Corps to authorize activities in waters of the U.S., including wetlands and other waters within the Plan's permit area. The Local Partners anticipate that the RGP would be consistent with the current Nationwide permit program, seeking programmatic coverage for impacts to waters of the U.S. equal to or less than 0.5 acre and 300 linear feet. In certain instances, the

RGP may allow for a slightly increased level of impact to waters of the U.S. Once adopted, the RGP would need to be renewed every 5 years.

Implementation of the proposed RGP is expected to substantially streamline Section 404. Issuance of a Section 404 permit often requires the Corps to consult with USFWS to comply with Section 7 of the ESA. This consultation would address the federally listed species covered by the Plan. Accordingly, it is expected that USFWS will not require any mitigation beyond that already required by the Plan. The Section 7 biological opinions issued for this Plan can also serve as the basis for any future biological opinions in the study area for covered activities. In addition, the conservation actions for impacts to wetlands in this Plan may fully satisfy Corps requirements for wetland mitigation.

## **Clean Water Act Section 401 and the Porter-Cologne Water Quality Control Act**

Under Clean Water Act Section 401, states have the authority to certify federal permits for discharges to waters under state jurisdiction. States may review proposed federal permits (e.g., Section 404 permits) for compliance with state water quality standards. The permit cannot be issued if the state denies certification. In California, the State Water Resources Control Board (State Board) and the Regional Water Quality Control Boards (usually referred to as the Regional Boards) are responsible for the issuance of Section 401 certifications.

The Porter-Cologne Water Quality Control Act is the primary state law concerning water quality. It authorizes the State Board and Regional Boards to prepare management plans such as regional water quality plans (RMC Water and Environment, Jones & Stokes 2006) to address the quality of groundwater and surface water. The Porter-Cologne Water Quality Control Act also authorizes the Regional Boards to issue waste discharge requirements defining limitations on allowable discharge to waters of the state. In addition to issuing Section 401 certifications on Section 404 applications to fill waters, the Regional Boards may also issue waste discharge requirements for such activities. Because the authority for waste discharge requirements is derived from the Porter-Cologne Water Quality Control Act and not the Clean Water Act, waste discharge requirements may apply to a somewhat different range of aquatic resources than do Section 404 permits and Section 401 Water Quality certifications. Applicants that obtain a permit from the Corps under Section 404 must also obtain certification of that permit by the Regional Board with jurisdiction over the project site. In the permit area, the San Francisco Regional Board has jurisdiction over the San Francisco Bay watershed, and the Central Coast Regional Board has jurisdiction over the Monterey Bay watershed. The Plan does not include certifications under Section 401 or waste discharge requirements under the Porter-Cologne Water Quality Control Act. These authorizations, if required, must be obtained separately. The Local Partners intend to work with the local Regional Boards to develop a coordinated process for obtaining required permits.

## Lake or Streambed Alteration Agreement

CDFG has jurisdictional authority over streams, lakes, and wetland resources associated with these aquatic systems under California Fish and Game Code Section 1600 et seq. California Fish and Game Code Section 1600 et seq. was repealed and replaced in October 2003 with new Sections 1600–1616 that took effect on January 1, 2004. CDFG has the authority to regulate work that will “substantially divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of, any river, stream, or lake, or deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake.” Activities of any person, state, or local governmental agency, or public utility are regulated by CDFG under Section 1602 of the Code. CDFG enters into a streambed or lakebed alteration agreement with the project proponent and can impose conditions on the agreement to ensure no net loss of values or acreage of the stream, lake, associated wetlands, and associated riparian habitat.

The lake or streambed alteration agreement is not a permit, but rather a mutual agreement between CDFG and the project proponent. Because CDFG includes under its jurisdiction streamside habitats that may not qualify as wetlands under the Clean Water Act definition, CDFG jurisdiction may be broader than Corps jurisdiction.

A project proponent must submit a notification of streambed alteration to CDFG before construction. The notification requires an application fee for streambed alteration agreements, with a specific fee schedule to be determined by CDFG. Many of the concerns raised by CDFG during streambed alteration agreement negotiations are related to special-status species. Activities covered by this Plan that need a streambed alteration agreement are expected to fully meet the standards of the streambed alteration agreement through compliance with this Plan for species covered by the Plan.

### 1.3.6 National Historic Preservation Act

Section 106 of the National Historic Preservation Act (NHPA) of 1966, as amended (16 U.S.C. 470 et seq.), requires Federal agencies to take into account the effects of their actions proposed on properties eligible for inclusion in the National Register of Historic Places. "Properties" are defined as "cultural resources", which includes prehistoric and historic sites, buildings, and structures that are listed on or eligible to the National Register of Historic Places. An undertaking is defined as a project, activity, or program funded in whole or in part under the direct or indirect jurisdiction of a Federal agency, including those carried out by or on behalf of a Federal agency; those carried out with Federal financial assistance; those requiring a Federal permit, license or approval; and those subject to state or local regulation administered pursuant to a delegation or approval by a Federal agency. The issuance of an incidental take permit is an undertaking subject to Section 106 of the NHPA. The USFWS has determined that the area of potential effects for the present undertaking is that area where on-

the-ground project activities will result in take of species. The NHPA and the potential effects of the conservation strategy on resources subject to the NHPA are discussed in detail in the EIR/EIS.

## 1.4 Overview of HCP/NCCP Planning Process

### 1.4.1 Organization of the Planning Process

The Habitat Plan was a coordinated effort by six local agencies (i.e., the Permittees).

- City of Gilroy.
- City of Morgan Hill.
- City of San José.
- County of Santa Clara.
- Santa Clara Valley Water District.
- Santa Clara Valley Transportation Authority.

Although not a Permittee, the Santa Clara County Open Space Authority was also involved in preparing the Plan. Coordination and management of the Plan involved the legislative governing bodies of the six Local Partners, a *Liaison Group* consisting of designated elected officials from each of the Local Partners, a *Management Team* of senior staff managers from each of the Permittees, and a *Stakeholder Group*. A Habitat Plan Program Manager reported to the Management Team and was responsible for day-to-day administration of the planning effort. Each group is described below.

The legislative governing bodies of each Local Partner were responsible for making significant decisions, such as approval or amendment of the Planning Agreement with CDFG and USFWS, approval of project financing, approval of the EIS/EIR, and approval of the draft and final Habitat Plan.

### 1.4.2 Liaison Group

Elected officials from each Local Partner's legislative body met regularly (i.e., at least every other month) as part of the Liaison Group to review and provide guidance on issues to be acted on by the Elected Bodies as well as issues of concern to the Management Team.

### 1.4.3 Stakeholder Group

In October 2005, the Management Team, after consultations with the Liaison Group, established a Stakeholder Group. The Stakeholder Group's approximately 25 members represented a wide variety of interests, including conservation organizations, business and development interests, landowners, agricultural interests, open space land-management organizations, and the general public. The Stakeholder Group, which met monthly, reviewed technical and policy issues and made recommendations to staff and elected officials. Meetings were attended by staff from the Local Partners and the Wildlife Agencies, the Program Manager, and, as needed, consultants. The Stakeholder Group, which was facilitated by a consultant, strove to achieve consensus. When consensus was not possible, all views were reported to the Management Team and, when applicable, to the Liaison Group and the Elected Bodies.

### 1.4.4 Science Advisors

Under its Five-Point Policy, USFWS “encourage[s] the use of scientific advisory committees during development and implementation of an HCP” (65 FR 106 35256, June 1, 2000). Independent scientific input is required by the NCCP Act [Section 2810(b)(5)]. The CDFG provides guidelines for “obtaining independent scientific analysis and input, to assist ... plan participants in meeting scientifically sound principles for the conservation and management of species” for assembling a science advisory group, defining their scope of work, involving a facilitator, and providing scientific advice (California Department of Fish and Game 2002). The science advisory process for the Santa Clara Valley Habitat Plan was guided by CDFG's guidelines.

The Local Partners felt that independent scientific input early in the planning process was critical to the success of the Plan. Names of potential advisors were suggested by Local Partners, Wildlife Agencies, and a consultant hired specifically to help develop and run the selection process, plan and implement the Science Advisors workshop, and coordinate preparation of the Science Advisors final report. None of the scientists was affiliated with the Santa Clara Valley Habitat Plan or the Local Partners. Qualifications of candidates included academic record, publications, and practical experience in the study area or with the covered species. Scientists were selected based on their qualifications within the areas of expertise listed below:

- conservation planning, reserve design, and wildlife corridors;
- vegetation ecology (with an emphasis on grassland ecology and rangeland management);
- ecological modeling;
- aquatic ecology/fisheries (with knowledge of salmonids<sup>19</sup>);

<sup>19</sup> The science advisory process occurred while fish were being considered for coverage by the Local Partners and the Wildlife Agencies, including NMFS.

- hydrology, watershed planning, and fluvial geomorphology;
- plant conservation biology (with experience in local serpentine plants, oak woodlands, or riparian sycamore systems);
- herpetology (with emphasis on locally rare amphibians and reptiles);
- ornithology (with an emphasis on local bird species); and
- invertebrate ecology (with emphasis on metapopulation theory; rare species conservation and recovery).

Science Advisors were also selected based on their availability to actively participate in the process. A two-day workshop was held July 6 and 7, 2006. A portion of this workshop was open to the public. Other components included a group field trip and a closed-door session at which time the advisors could talk amongst themselves without the Local Partners or their consultants present. Topics considered by the advisors included the following:

- evaluation of data adequacy for inclusion in the Plan,
- identification of data gaps and sources of uncertainty,
- formulation of biological goals and objectives to conserve covered species and natural communities,
- identification of preserve-design principles and scientifically sound conservation measures for the local area, and
- development of monitoring and adaptive management guidelines for covered species and habitats.

The Science Advisors produced a report documenting their findings that was made available to the public in December 2006. The Local Partners considered all comments from the Science Advisors' final report when developing the Plan. Some Science Advisors were also consulted at various times during Plan development for their advice or review.

A separate group of science advisors was convened on October 1, 2010 to review the working draft of the western burrowing owl conservation strategy. These science advisors were selected based on their expertise with the species locally in the study area and in southern San Francisco Bay.

## 1.4.5 Management Team

The Management Team, which had primary responsibility for developing the Plan, was made up of senior managers from each Local Partner. The Management Team, Plan Program Manager, and key representatives of the consultants generally met monthly. Responsibilities included making decisions that were outside the responsibility of the Elected Bodies and providing direction to local staff working on the Plan, consultants, and the Plan Program Manager. The Management Team and Program Manager actively and regularly coordinated with representatives of the three Wildlife Agencies in development of the Plan.

## 1.4.6 Local Agency and Wildlife Agency Technical Coordination

Representatives of the Local Partners, consultants, and the Wildlife Agencies held monthly meetings to address project coordination and technical issues.

## 1.4.7 Consultant Team

This Plan was prepared by a consultant team under the guidance and direction of the Management Team and the Liaison Group. The Consulting Team consisted of scientific, planning, legal, and other technical staff from ICF International (formerly Jones & Stokes) in San José, Oakland, San Francisco, and Sacramento; Moore Iacofano Goltsman (MIG) in Berkeley; Kleinschmidt Associates in Grass Valley; Land Use Planning Services in Palo Alto; Willdan (formerly MuniFinancial) and Hausrath Associates in Oakland; Albion Environmental in Santa Cruz; Dr. Jerry Smith (San José State University); Resources Law Group in Sacramento; and CH2M Hill in Sacramento.

The members of the Consulting Team had the following responsibilities.

- Land Use Planning Services: Program Management.
- ICF International: development of the Plan and public outreach.
- MIG: stakeholder facilitation.
- Kleinschmidt Associates: Science Advisors selection and facilitation.
- Willdan (MuniFinancial) and Hausrath Economics Group: cost and funding analysis (with assistance from ICF International).
- Albion Environmental: western burrowing owl analysis.
- Dr. Jerry Smith: aquatic analysis.
- Lawrence Ford, Ph.D., LD Ford Rangeland Conservation Science: rangeland conservation.
- CH2M Hill: EIS/EIR preparation.
- Resources Law Group: Implementing Agreement drafting and other legal documents.

## 1.4.8 Public Outreach and Involvement

Public involvement has been an integral part of the process of developing this Plan. Stakeholders and the public have been actively involved throughout the planning process and have had the following opportunities to provide their input and influence the development of the Plan:

- at least quarterly public meetings of the Liaison Group,

- approximately monthly public meetings of the Stakeholder Group,
- a public workshop of the Habitat Plan Science Advisors,
- community public meetings hosted by the Local Partners at key project milestones (approximately one per year),
- public scoping and public-involvement meetings associated with the CEQA/NEPA process,
- periodic presentations to official governing bodies of participating agencies (e.g., boards, councils, planning commissions),
- many presentations to interested organizations upon request, and
- approximately annual training sessions and tours.

In addition, a website announcing all public meetings, posting all public documents, and accepting comments and feedback was used to engage and inform the public.

The Local Partners developed this Plan in compliance with public involvement guidelines established by USFWS and NMFS (U.S. Fish and Wildlife Service and National Marine Fisheries Service 1996) and the requirements of the NCCP Act.

## 1.5 Document Organization

This Plan and supporting information are presented in the chapters and appendices listed below. Volumes 1, 2, and 3 contain the Habitat Plan, and Volume 4 contains all appendices.

### Volume 1

- Chapter 1, *Introduction*, discusses the background, purpose, and objectives of the Plan; reviews the regulatory setting; and summarizes the Habitat Plan process.
- Chapter 2, *Land Use and Covered Activities*, describes the land uses of the study area and the activities covered under the Plan.
- Chapter 3, *Physical and Biological Resources*, describes the existing conditions of the study area relevant to the Plan.

### Volume 2

- Chapter 4, *Impact Assessment and Level of Take*, presents the impacts of the covered activities.
- Chapter 5, *Conservation Strategy*, summarizes the conservation strategy and describes the specific conservation actions to be implemented to mitigate the

impacts of the covered activities and contribute to the recovery of the covered species.

- Chapter 6, *Conditions on Covered Activities and Application Process*, describes the specific surveys and other actions required of all covered activities to avoid and minimize impacts to covered species consistent with federal and state regulations.

### Volume 3

- Chapter 7, *Monitoring and Adaptive Management Program*, discusses the monitoring requirements and adaptive management procedures associated with implementation of conservation actions and reserve management.
- Chapter 8, *Plan Implementation*, details the administrative requirements associated with Plan implementation and the roles and responsibilities of the Permittees and Wildlife Agencies.
- Chapter 9, *Costs and Funding*, reviews the costs associated with Plan implementation and the funding sources proposed to pay for those costs.
- Chapter 10, *Assurances*, describes the protections for Permittees and neighboring landowners in the event of changed circumstances or unforeseen circumstances, as well as the procedures for modifying or amending the Plan.
- Chapter 11, *Alternatives to Take*, presents the required analysis of alternatives to take of covered species.
- Chapter 12, *List of Preparers*, identifies the individuals involved in the preparation of this document.
- Chapter 13, *Literature Cited*, is a comprehensive bibliography of references cited in the text.

### Volume 4

- Appendix A, *Glossary*, is a list of terms and their definitions used in this document.
- Appendix B, *Implementing Agreement*, is a copy of the Implementing Agreement that will be entered into by the Permittees and the Wildlife Agencies. This appendix includes three attachments including a covered species list, the *Implementing Ordinance Template*, and the *Neighboring Landowner Certificate of Inclusion*.
- Appendix C, *Evaluation of Special-Status Species for Coverage in the Habitat Plan*, lists the special-status species that were considered for coverage under this Plan, their legal status, their coverage under the Plan (covered or not covered status), and the rationale for coverage.
- Appendix D, *Species Accounts*, presents detailed ecological accounts of all covered species, including models of habitat distribution (i.e., habitat models) that were developed for selected species.

- Appendix E, *Nitrogen Deposition Contribution Estimates*, provides a technical report on the effects of covered activities on airborne nitrogen and its deposition on serpentine grasslands and other habitats in the study area.
- Appendix F, *Climate Change Analysis*, provides technical details supporting the discussion of the potential effects of climate change on the Reserve System and covered species.
- Appendix G, *Cost Model*, describes the cost model used to estimate Plan costs described in Chapter 9.
- Appendix H, *Conservation Easement Template*, is the template that will be used for conservation easements that protect Reserve System lands.
- Appendix I. Not used.
- Appendix J, *Monitoring at Different Levels*, describes the three levels at which monitoring is conducted. This technical detail supports Chapter 7.
- Appendix K, *California Tiger Salamander Hybridization*, provides technical details supporting the conservation strategy for California tiger salamander in Chapter 5.
- Appendix L, *Fish Habitat Assemblage Data*, provides an overview of mapping methods and results for native fish communities in the study area.
- Appendix M, *Western Burrowing Owl Conservation Strategy*, provides details on the conservation strategy for the western burrowing owl which are summarized in Chapter 5.
- Appendix N, *Burrowing Owl Population Viability Analysis Santa Clara Valley Habitat Conservation Plan/Natural Communities Conservation Plan (HCP/NCCP)—March 2010*, is a technical report supporting the western burrowing owl conservation strategy (Appendix M).
- Appendix O, *List of Acronyms and Abbreviations*, lists the acronyms and abbreviations used in this document. It can be folded out for convenient reference.

**Table 1-1.** Local Planning Documents and Time Horizons Relevant to the Permit Term

Document	Date Produced	Projection/ Time Horizon	Plan Duration
Bay Area Integrated Regional Water Management Plan (SCVWD)	2006	2026	20 years
City of Gilroy General Plan	2000 (adopted in 2002)	2020	18 years

**Table 1-3. Checklist for NCCP Act Requirements**

Requirement (Fish and Game Code Section)	Applicable Habitat Plan Sections <sup>1</sup>
The plan was developed in accordance with the process identified in the planning agreement per Section 2810. (2820(a)(1))	Chapter 1 <i>Introduction</i> , Section 1.1.3 <i>Background</i> and Section 1.3.1 <i>Federal and State Endangered Species Laws</i> subheading <i>Natural Community Conservation Planning Act</i> Chapter 8 <i>Plan Implementation</i> , Section 8.6.2 <i>Land Acquired by Other Organizations or through Partnerships</i> subheading <i>Land Acquisition during Plan Development (Interim Conservation)</i>
The plan integrates adaptive management strategies that are periodically evaluated and modified based on information from monitoring programs and other sources; these strategies assist conservation of covered species and ecosystems within the plan area. (2820(a)(2))	Chapter 5, <i>Conservation Strategy</i> , Section 5.3, <i>Conservation Actions</i> Chapter 6 <i>Conditions on Covered Activities and Application Process</i> , Section 6.3 <i>Conditions on All Covered Activities</i> Chapter 7 <i>Monitoring and Adaptive Management Program</i> , Section 7.1.1 <i>Regulatory Context</i> , Section 7.1.2 <i>Adaptive Management</i> , and Section 7.3 <i>Monitoring and Management Actions</i> Figure 7-2 <i>Adaptive Management Process</i>
[The plan] Protects habitat, natural communities, and species diversity on a landscape or ecosystem basis through the creation and long-term management of habitat reserves or other measures that provide equivalent conservation of covered species appropriate for land, aquatic, and marine habitats within the plan area. (2820(a)(3))	Chapter 1 <i>Introduction</i> , Section 1.1.2 <i>Purpose</i> Chapter 5 <i>Conservation Strategy</i> , Section 5.2.3 <i>Reserve System</i> , Section 5.2.4 <i>Aquatic Habitat Protection and Enhancement</i> , Section 5.2.5 <i>Land Management</i> , Section 5.3.1 <i>Land Acquisition and Restoration Actions</i> through Section 5.3.7 <i>Wetland and Pond Conservation and Management</i>
[The plan] Conserves, restores, and manages representative natural and semi-natural landscapes to maintain the ecological integrity of large habitat blocks, ecosystem function, and biological diversity. (2820(a)(4)(A))	Chapter 3 <i>Physical and Biological Resources</i> , Section 3.3.1 <i>Definitions</i> , Section 3.3.4 <i>Biological Diversity of the Study Area</i> , and Section 3.3.5 <i>Natural Communities and Land-Cover Types</i> (ecosystems discussed in each Natural Community) Chapter 5 <i>Conservation Strategy</i> , Section 5.2.3 <i>Reserve System</i> , Section 5.2.4 <i>Aquatic Habitat Protection and Enhancement</i> , Section 5.2.5 <i>Land Management</i> , Section 5.3.1 <i>Land Acquisition and Restoration Actions</i> through Section 5.3.7 <i>Wetland and Pond Conservation and Management</i>
[The plan] Establishes one or more reserves or proposes other measures that provide equivalent conservation of covered species within the plan area and linkages between them and adjacent habitat areas outside of the plan area. (2820(a)(4)(B))	Chapter 5 <i>Conservation Strategy</i> , Section 5.2.3 <i>Reserve System</i> subheading <i>Landscape Linkages</i> , Section 5.2.4 <i>Aquatic Habitat Protection and Enhancement</i> , and Section 5.3.1 <i>Land Acquisition and Restoration Actions</i> Table 5-9 <i>Landscape Linkages in and Near the Study Area Considered for the Reserve Design</i> Table 5-5 <i>Existing Open Space and Interim Conservation Lands Proposed for the Reserve System and Specific Conservation Actions within Each Site</i> Figure 5-6 <i>Potential Landscape Linkages in and Near the Study Area</i> Figure 5-8 <i>Land Acquisition Strategy with Applicable Landscape Linkages</i>

Requirement (Fish and Game Code Section)	Applicable Habitat Plan Sections <sup>1</sup>
[The plan] Protects and maintains habitat areas that are large enough to support sustainable populations of covered species. (2820(a)(4)(C))	<p>Chapter 5 <i>Conservation Strategy</i>, Section 5.2.1 <i>Biological Goals and Objectives</i> subheading <i>Natural Community–Level Goals</i>, and Section 5.4 <i>Benefits of and Additional Conservation Actions for Covered Species</i> (descriptions for each covered species)</p> <p>Table 5-16 <i>Species Occurrences, Impacts, and Conservation Requirements for Covered Plants</i></p> <p>Table 5-17 <i>Commitments to Acquire and Enhance Modeled Habitat in the Reserve System for Covered Species with Models (acres)</i></p>
[The plan] Sustains the effective movement and interchange of organisms between habitat areas to maintain ecological integrity of habitat within the plan area. (2820(a)(4)(E))	<p>Chapter 3 <i>Physical and Biological Resources</i>, Section 3.3.1 <i>Definitions</i> subheading <i>Ecological Integrity</i></p> <p>Chapter 5 <i>Conservation Strategy</i>, Section 5.2.3 <i>Reserve System</i> subheading <i>Landscape Linkages</i>, Section 5.2.4 <i>Aquatic Habitat Protection and Enhancement</i>, Section 5.3.1 <i>Land Acquisition and Restoration Actions</i>, and Section 5.3.2 <i>Landscape Conservation and Management</i> subheading <i>Connectivity and Permeability</i></p> <p>Table 5-9 <i>Landscape Linkages in and Near the Study Area Considered for the Reserve Design</i></p> <p>Figure 5-6 <i>Potential Landscape Linkages in and Near the Study Area</i></p> <p>Figure 5-8 <i>Land Acquisition Strategy with Applicable Landscape Linkages</i></p>
The plan incorporates a range of environmental gradients (such as slope, elevation, aspect, and coastal or inland characteristics) and high habitat diversity; this provides for shifting distributions of species due to changed circumstances. (2820(a)(4)(D))	<p>Chapter 3 <i>Physical and Biological Resources</i>, Section 3.2.2 <i>Topography</i>, Section 3.2.4 <i>Soils</i>, Section 3.2.5 <i>Climate and Hydrology</i>, Section 3.3.1 <i>Definitions</i> subheading <i>Environmental Gradients</i></p> <p>Figure 3-1 <i>Santa Clara Valley HCP/NCCP Topography</i></p> <p>Figure 3-2 <i>Santa Clara Valley HCP/NCCP Slope in Degrees</i></p> <p>Figure 3-3 <i>Soils in the Santa Clara Valley HCP/NCCP Area</i></p> <p>Figure 3-4 <i>Santa Clara Valley HCP/NCCP Serpentine Areas</i></p> <p>Figure 3-5 <i>Average Annual Rainfall in HCP/NCCP Study Area</i></p> <p>Figure 3-6 <i>Santa Clara Valley HCP/NCCP Watersheds</i></p> <p>Chapter 5 <i>Conservation Strategy</i>, Section 5.3.2 <i>Landscape Conservation and Management</i> subheading <i>Biological Goals and Objectives</i></p> <p>Table 5-1a <i>Biological Goals, Objectives and Conservation Actions: Landscape Level</i></p> <p>Table 5-11 <i>Land Acquisition and Enhancement Requirements within the Study Area for Selected Terrestrial Land-Cover Types (acres)</i></p>

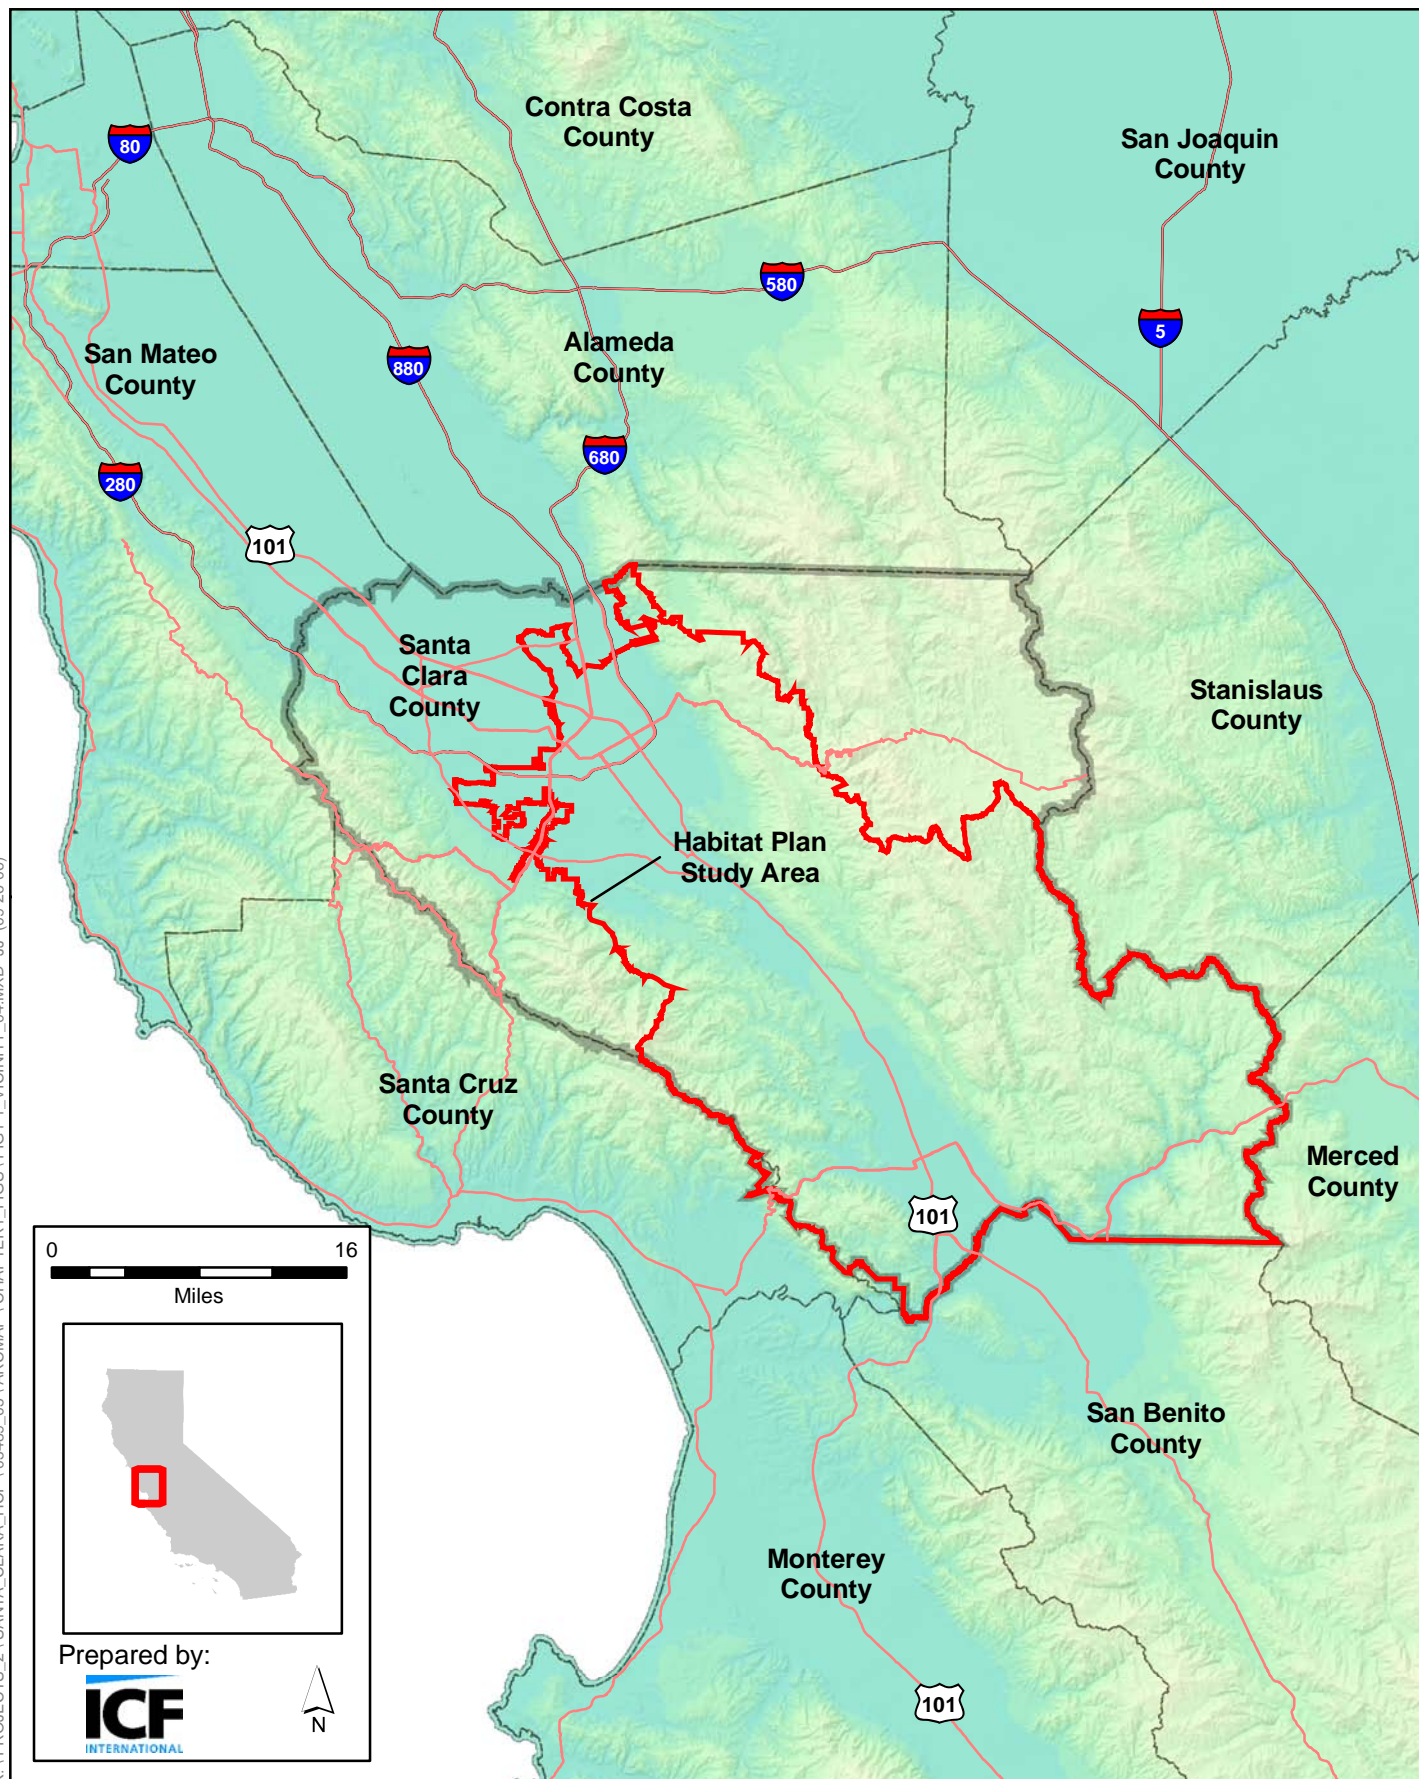

Requirement (Fish and Game Code Section)	Applicable Habitat Plan Sections <sup>1</sup>
The plan identifies allowable activities and restrictions within reserve areas compatible with conservation of species, habitats, natural communities, and associated ecological functions. (2820(a)(5))	<p>Chapter 2 <i>Land Use and Covered Activities</i>, Section 2.3.8 <i>Conservation Strategy Implementation</i></p> <p>Chapter 4 <i>Impact Assessment and Level of Take</i>, Section 4.3.7 <i>Conservation Strategy Implementation</i> subheading <i>Activities within the Reserve System</i></p> <p>Chapter 6 <i>Conditions on Covered Activities and Application Process</i>, Section 6.4.6 <i>Reserve System Implementation</i> subheadings <i>Condition 9. Prepare and Implement a Recreation Plan</i> and <i>Condition 10. Fuel Buffer</i>, Section 6.5 <i>Conditions to Minimize Impacts on Natural Communities</i> subheading <i>Condition 11. Stream and Riparian Setbacks</i> (most other Conditions also apply to the Reserve System)</p>
The plan contains specific conservation measures that meet the biological needs of covered species and that are based on the best available scientific information about the status of covered species and the impacts of permitted activities on those species. (2820(a)(6))	<p>Chapter 3 <i>Physical and Biological Resources</i>, Section 3.3.3 <i>Covered Species</i></p> <p>Chapter 5 <i>Conservation Strategy</i>, Section 5.4 <i>Benefits of and Additional Conservation Actions for Covered Species</i></p> <p>Table 5-1c <i>Biological Goals, Objectives and Conservation Actions: Wildlife</i></p> <p>Table 5-1d <i>Biological Goals, Objectives and Conservation Actions: Plants</i></p> <p>Chapter 6 <i>Conditions on Covered Activities and Application Process</i></p> <p>Appendix D <i>Species Accounts</i> (for best available scientific information on the covered species)</p>
The plan contains a monitoring program. (2820(a)(7))	Chapter 7 <i>Monitoring and Adaptive Management Program</i>
The plan contains an adaptive management program. (2820(a)(8))	Chapter 7 <i>Monitoring and Adaptive Management Program</i>
The plan includes an estimated timeframe and process for implementing reserves or other conservation measures, including obligations of landowners and plan signatories and consequences for failure to acquire lands in a timely manner. (2820(a)(9))	<p>Chapter 5 <i>Conservation Strategy</i>, Section 5.3.1 <i>Land Acquisition and Restoration Actions</i> subheading <i>Stay-Ahead Provision and Rough Proportionality</i></p> <p>Tables 5-1a and 5-1b <i>Biological Goals, Objectives and Conservation Actions: Landscape-Level and Natural Community-Level</i></p> <p>Table 5-14 <i>Commitments by Time Period for Restoration and Creation Requirements that Contribute to Species Recovery</i></p> <p>Chapter 8 <i>Plan Implementation</i>, Section 8.6.1 <i>Stay-Ahead Provision</i></p>
The plan ensures that mitigation and conservation measures are roughly proportional in time and extent to the impact on habitat or covered species authorized under the plan. These provisions identify (a) the conservation measures—including assembly of reserves where appropriate and implementation of monitoring and management activities—that the landowner will maintain or carry out in rough proportion to the impact on habitat or covered species and (b) the measurements that will be used to determine if this occurs. (2820(b)(3)(D)(9))	<p>Chapter 5 <i>Conservation Strategy</i>, Section 5.3.1 <i>Land Acquisition and Restoration Actions</i> subheading <i>Stay-Ahead Provision and Rough Proportionality</i></p> <p>Table 5-1a <i>Biological Goals, Objectives and Conservation Actions: Landscape Level</i></p> <p>Table 5-1b <i>Biological Goals, Objectives and Conservation Actions: Natural Community Level</i></p> <p>Table 5-1c <i>Biological Goals, Objectives and Conservation Actions: Wildlife</i></p> <p>Table 5-1d <i>Biological Goals, Objectives and Conservation Actions: Plants</i></p>

Requirement (Fish and Game Code Section)	Applicable Habitat Plan Sections <sup>1</sup>
	<p>Table 5-11 <i>Land Acquisition and Enhancement Requirements within the Study Area for Selected Terrestrial Land-Cover Types</i> (acres)</p> <p>Table 5-12 <i>Required Preservation, Enhancement, Restoration and Creation Mitigation Ratios and Estimated Acquisition, Enhancement, Restoration, and Creation Requirements for Aquatic Land Cover Types</i></p> <p>Table 5-16 <i>Species Occurrences, Impacts, and Conservation Requirements for Covered Plants</i></p> <p>Chapter 8 <i>Plan Implementation</i>, Section 8.6.1 <i>Stay-Ahead Provision</i></p>
The plan ensures adequate funding to carry out the conservation measures identified in the plan. (2820(a)(10))	<p>Chapter 9 <i>Costs and Funding</i>, Section 9.4 <i>Funding Sources and Assurances</i></p> <p>Table 9-5 <i>Funding Sources</i></p>
<p>The plan defines species coverage, including any conditions of coverage (2820(b)(1)).</p> <p>The plan establishes long-term protection of habitat reserves or provides equivalent conservation of covered species (2820(b)(2)).</p>	<p>Chapter 3 <i>Physical and Biological Resources</i>, Section 3.3.3 <i>Covered Species</i></p> <p>Chapter 5 <i>Conservation Strategy</i>, Section 5.2.3 <i>Reserve System</i>, Section 5.2.4 <i>Aquatic Habitat Protection and Enhancement</i>, and Section 5.3.1 <i>Land Acquisition and Restoration Actions</i></p>
<p>The plan defines specific terms and conditions, which, if violated, would result in the suspension or revocation of the permit, in whole or in part. CDFG will include a provision requiring notification to the plan participant of a specified period of time to cure any default prior to suspension or revocation of the permit in whole or in part. These terms and conditions will address, but are not limited to, provisions specifying the actions CDFG will take under all of the following circumstances (2820(b)(3)):</p> <p>The plan participant fails to provide adequate funding.</p> <p>The plan participant fails to maintain the rough proportionality between impacts on habitat or covered species and conservation measures.</p> <p>The plan participant adopts, amends, or approves any plan or project without the concurrence of the wildlife agencies that is inconsistent with the objectives and requirements of the approved plan.</p> <p>The level of take exceeds that authorized by the permit.</p>	<p>Chapter 5 <i>Conservation Strategy</i>, Section 5.3.1 <i>Land Acquisition and Restoration Actions</i> subheading <i>Stay-Ahead Provision and Rough Proportionality</i></p> <p>Chapter 6, <i>Conditions on Covered Activities and Application Process</i>, Section 6.1 <i>Introduction</i> (regarding approval of plans or project inconsistent with the Plan)</p> <p>Chapter 8 <i>Plan Implementation</i>, Section 8.6.1 <i>Stay-Ahead Provision</i></p> <p>Chapter 9 <i>Costs and Funding</i>, Section 9.4 <i>Funding Sources and Assurances</i>, Section 9.4.4 <i>Funding Adequacy</i></p> <p>Table 9-5 <i>Funding Sources</i></p> <p>Implementing Agreement, Section 16.3 <i>Suspension of the State Permit</i></p>
The plan specifies procedures for amendment of the plan and the implementation agreement (2820(b)(4)).	Chapter 10 <i>Assurances</i> , Section 10.3 <i>Modifications to the Plan</i>
The plan ensures implementation of a monitoring program and adaptive management program. (2820(b)(5)).	Chapter 7 <i>Monitoring and Adaptive Management Program</i> , Section 7.1.1 <i>Regulatory Context</i>
The plan provides for oversight of plan implementation to assess mitigation performance, funding, and habitat protection measures. (2820(b)(6))	Chapter 8 <i>Plan Implementation</i> , Section 8.3.8 <i>Reserve Management and Monitoring</i> subheading <i>Structure of the Adaptive Management Decision-Making Process</i> and Section 8.10 <i>Data Tracking</i>

Requirement (Fish and Game Code Section)	Applicable Habitat Plan Sections <sup>1</sup>
The plan provides for periodic reporting to the wildlife agencies and the public for purposes of information and evaluation of plan progress. (2820(b)(7))	Chapter 8 <i>Plan Implementation</i> , Section 8.11 <i>Reporting</i>
The plan provides mechanisms to ensure adequate funding to carry out the conservation actions identified in the plan. (2820(b)(8))	Chapter 9 <i>Costs and Funding</i> , Section 9.4 <i>Funding Sources and Assurances</i> Table 9-5 <i>Funding Sources</i>
The plan stipulates that if a participant does not maintain proportionality between <i>take</i> and conservation measures specified in the implementation agreement and does not either (a) cure the default within 45 days or (b) enter into an agreement with CDFG within 45 days to expeditiously cure the default, CDFG will suspend or revoke the permit, in whole or in part. (2820(c))	Chapter 8 <i>Plan Implementation</i> , Section 8.6.1 <i>Stay-Ahead Provision</i> subheading <i>Measurement of Stay-Ahead Provision</i> Implementing Agreement, Section 16.3.1 <i>Failure to Maintain Rough Proportionality</i>
The plan requires that data and reports associated with monitoring programs be available for public review; the landowner must also conduct public workshops on an annual basis to provide information and evaluate progress toward attaining the conservation objectives of the plan. (2820(d))	Chapter 7 <i>Monitoring and Adaptive Management Program</i> , Section 7.4 <i>Data and Reporting</i> , and Section 7.2.3 <i>Program Implementation</i> subheading <i>Program Infrastructure</i> Chapter 8 <i>Plan Implementation</i> , Section 8.2.7 <i>Public Input</i> , and Section 8.11 <i>Reporting</i>
Note:	
<sup>1</sup> Only the primary applicable sections of the Plan are listed. Other sections may apply or be cross-referenced by the sections listed in this table.

## Chapter 2

# Land Use and Covered Activities

## 2.1 Introduction

This chapter examines existing land use conditions and land use plans in the study area, and describes activities covered under the Plan. The land use component of this chapter provides an overview of the major land use and open space management agencies operating within the study area and provides a brief description of each agency's mission and jurisdiction. The description of land use provides the necessary context for the covered activities upon which the impact analysis (Chapter 4) is based. This chapter provides history and context for future development in the study area, reviews existing land-use conditions and relevant land use plans; presents the criteria used to determine land use categories for the Plan; discusses significant existing open spaces in the study area and open space type classification; and describes the projects and activities within the permit area that will be covered under the incidental take permits.

## 2.2 Land Use and Jurisdictions

### 2.2.1 Existing Conditions

Santa Clara County encompasses 835,449 acres (1,305 square miles), 519,506 acres (810 square miles, or 62% of the County) of which are included in the study area of this Plan. The fertile Santa Clara Valley (Valley) runs the entire length of the County from north to south, ringed by the rolling hills of the Diablo Range on the east and the Santa Cruz Mountains on the west. Salt marshes, tidal wetlands, and mostly abandoned salt ponds lie in the northern part of the County, adjacent to San Francisco Bay (County of Santa Clara 2006a) (see **Figure 1-1** for the regional location of the Plan study area).

The Valley is generally split into two geographic regions, the North Valley and the South Valley. The North Valley is extensively urbanized and houses approximately 90% of the County's residents. Thirteen of the County's fifteen cities are located in the North Valley, while the remaining two cities, Gilroy and Morgan Hill, are located in the South Valley. The South Valley remains predominantly rural, with the exception of Gilroy, Morgan Hill, small unincorporated community of San Martin, and scattered residential areas generally having parcels of five acres or smaller that were created in or before the

1960s. Low-density residential developments are also scattered along the Valley floor and foothill areas (County of Santa Clara 2006b).

Once known as the “Valley of Heart’s Delight,” orchards and other agriculture dominated this area in the early to mid-20th century. Over the past several decades, the County has transformed into “Silicon Valley,” a major global center of high-tech development and the Internet boom of the 1990s. The population growth of the County reflected this dramatic shift in local industry. Between 1980 and 1990, Santa Clara County grew by 202,506 people (16%). Similarly, between 1990 and 2000, the County grew by an additional 185,008, a 12% increase in population. Between 1990 and 2000, most of the population growth in Santa Clara County occurred in San José and in the North Valley cities (Campbell, Cupertino, Los Altos, Los Altos Hills, Los Gatos, Milpitas, Monte Sereno, Mountain View, Palo Alto, Santa Clara, Saratoga, and Sunnyvale). Although North Valley cities experienced a larger increase in population numbers, the South Valley cities of Morgan Hill and Gilroy experienced a larger-than-average percentage increase in population (County of Santa Clara 2006b).

The County’s current population of over 1.7 million is one of the largest in the state and is the largest of the nine Bay Area counties. Its population constitutes approximately one-fourth of the Bay Area’s total population and the County provides more than 25% of all jobs in the Bay Area. Nearly 92% of the County population lives in its cities (County of Santa Clara 2006a). Of the fifteen cities located in Santa Clara County, only Gilroy, Morgan Hill, and San José are covered by the Plan.

It is predicted that the County’s population will continue to grow, but at a slower rate than in the recent past. Moderate rates of growth in employment and housing development may account for this slowdown in population growth (County of Santa Clara 2006b). According to the Association of Bay Area Governments, Santa Clara County’s population is projected to reach 1,855,500 by 2010 and 2,073,300 by 2020 (Association of Bay Area Governments 2005).

The Association of Bay Area Governments develops population projections for Bay Area cities and counties every two years. City populations generally include the full Local Agency Formation Commission (LAFCO)-defined sphere of influence. In 2005, the cities of Gilroy, Morgan Hill and San José had a total population of 1,079,500, 62% of the County’s population. The population of these cities is projected to reach 1,310,400 by 2010 and 1,455,800 by 2020, 62% and 63% of projected County population, respectively. The population of Santa Clara County exclusive of the cities was 15,400 (Association of Bay Area Governments 2005).

As early as 1970, the County and cities of the Valley anticipated this type of rapid growth and began implementing policies that would help guide development, curtail sprawl, and protect the abundant natural resources of the region. A critical policy was and is that urban growth would occur within cities and not in unincorporated Santa Clara County. After several decades, the County remains keenly aware of the need to guide development so that social, economic, and environmental resources are protected. Many of the policies in the current

County general plan address land use issues involving the rural unincorporated areas of the County over which the County has direct land use authority. The overall direction of these policies is to maintain the scenic rural character of these areas and to promote conservation and productive use of their natural resources for agriculture, ranching, watershed, public recreation, and wildlife habitat.

An important cornerstone of the County general plan is a vision of “compact development” as an overall approach to managing future growth. Compact development means that most future growth is directed into appropriate locations within existing urban areas, particularly along transit corridors and closer to employment centers rather than sprawling outward into the hillsides and the rural countryside.

The Cities of Gilroy, Morgan Hill, and San José maintain a strong commitment to protect the natural and agricultural resources surrounding their respective cities. Reflecting this vision, Morgan Hill and San José, have adopted an ultimate buildout line (termed the “planning limit of urban growth” for the purposes of this Plan). Gilroy’s General Plan 2020 urban expansion line may be extended in future general plan updates (for additional detail, see Section 2.4 *Projects and Activities Not Covered by this Plan*). More detail on each city’s development and open space policies, and planning limit of urban growth boundaries is provided below.

Background information for each of the Local Partners is provided below.

## Gilroy

Gilroy, known as the “Garlic Capital of the World,” is located close to the southern border of Santa Clara County where U.S. 101 intersects with State Route (SR) 152. Gilroy is known for its rural residential environment, its award-winning parks, and for its “urban forest,” for which the City has won Tree City USA awards annually since 1979 (City of Gilroy 2006a).

The City of Gilroy adopted its most recent general plan on June 13, 2002 (City of Gilroy 2002a). This document is a statement of community values and priorities, projecting out to the year 2020. The vision for Gilroy’s future emphasizes a compact pattern of development, surrounded by open space and working agricultural lands, helping to retain the City’s small-town character and rural atmosphere. In addition to the general plan, Gilroy recently developed the Hecker Pass Specific Plan to “protect and enhance the Hecker Pass Area’s rural character, open space, and agricultural uses” (City of Gilroy 2005b).

The City of Gilroy anticipates buildout of the city will occur within the existing general plan boundary over the course of the Plan permit term. Therefore, the City’s general plan boundary will be used to represent the City’s planning limit of urban growth for this Plan. The general plan boundary is the area of evaluation in the City of Gilroy General Plan that represents a 20-year

development time frame. The general plan was adopted in 2002 and represents a buildout to 2020 (C. Casper pers. comm.).

## Population, Housing, and Employment

The population of Gilroy was 47,671 people in 2005 and is projected to reach 64,600 in 2020 and 66,400 in 2030, an increase of 36% and 39% over 2005 values, respectively<sup>1</sup>.

Households in Gilroy numbered 15,450 in 2005. The number of households is projected to reach 18,350 in 2020 and 19,050 in 2030, an increase of 19% and 23% over 2005 values, respectively.

Jobs in Gilroy numbered 22,430, or 2.1% of total jobs Countywide, in 2005. The number of jobs is projected to reach 32,690 in 2020 and 34,950 in 2030, 2.8% and 2.6% of projected jobs Countywide, respectively (Association of Bay Area Governments 2005).

## Conservation and Open Space Policies

The City of Gilroy has adopted several policies related to protection and conservation of open space. A selection of these policies from the general plan and from the Hecker Pass Specific Plan is listed below (City of Gilroy 2002a, 2005b).

### Gilroy General Plan

**Policy 20.01, Open Space Areas; Policy 20.02, Creek Protection.** Ensure protection of creeks (including small canyons and seasonal creeks) that flow through the area, preserving their natural drainage function through adequate setbacks and easements.

**Policy 1.09, Clustered Development; Policy 20.01, Open Space Areas; Policy 20.03, Plant and Wildlife Habitats; Policy 20.04, Rare and Endangered Species.** Ensure protection of natural resource and wildlife habitat areas.

**Policy 1.09, Clustered Development; Policy 20.01, Open Space Areas.** Respect the natural topography to the greatest extent possible, retaining significant natural features such as hillsides, trees, and heavily vegetated areas.

---

<sup>1</sup> Population, housing, and employment information presented in this chapter is taken from the Association of Bay Area Governments 2005 projections. The projections for each city include lands currently annexed to the city, as well as all currently unincorporated lands within its sphere of influence. Projections for Santa Clara County do not include unincorporated lands within the sphere of influence of the cities. These boundaries are inconsistent with the local growth boundaries of the study-area cities, as discussed later in this chapter.

## Hecker Pass Specific Plan

**Development Controls and Design Standards: Open Space.** A variety of open space areas should be created through the design and development process, including active recreation areas, habitat protection areas, agricultural areas, scenic open spaces, and neighborhood open spaces (interspersed between clusters of residential development). For all open spaces, the Specific Plan should ensure (a) that open space dedications are permanent, and (b) that appropriate mechanisms are in place to address ongoing maintenance and management issues.

## Morgan Hill

Morgan Hill is located in southern Santa Clara Valley, approximately 12 miles south of San José, 10 miles north of Gilroy, and 15 miles inland from the Pacific Coast (City of Morgan Hill 2006). The City of Morgan Hill developed its current general plan in 2001 and made revisions to the plan in 2006 to adopt an urban limit line and greenbelt policies. The general plan envisions:

Morgan Hill keeping its small-town character while offering new opportunities for businesses and amenities for residents. Agriculture will continue at the outskirts, and new housing for a range of incomes will be accommodated in a variety of locations. Urban land uses will be encouraged around the downtown, and incentives would foster infill development instead of sprawl. (City of Morgan Hill 2006.)

The City of Morgan Hill anticipates ultimate buildout of the city will occur within its Urban Limit Line adopted in April, 2006. Therefore, the City's Urban Limit Line will be used to represent the City's planning limit of urban growth for this Plan. The Urban Limit Line separates urban and future urban areas from rural areas. The Urban Limit Line is a longer-term version of the City's Urban Growth Boundary and is intended to reflect the City's long-term policy for growth in Morgan Hill, beyond the 20-year time frame of the Urban Growth Boundary. The purpose of the Urban Limit Line is to encourage more efficient growth patterns, minimize public costs, and protect environmental resources. Some, but not all, of the land outside the Urban Limit Line has been identified as Greenbelt (S. Golden pers. comm.).

## Population, Housing, and Employment

The population of Morgan Hill was 36,423 people in 2005 and is projected to reach 48,000 in 2020 and 50,000 in 2030, an increase of 32% and 37% over 2005 levels, respectively.

Households in Morgan Hill numbered 13,330 in 2005. The number of households is projected to reach 15,590 in 2020 and 16,140 in 2030, an increase of 17% and 21% over 2005 values, respectively.

Jobs in Morgan Hill numbered 14,520, or 1.4% of total jobs Countywide, in 2005. The number of jobs is projected to reach 21,760 in 2020 and 25,570 in 2030, 1.9% and 2.1% of projected jobs Countywide, respectively (Association of Bay Area Governments 2005).

## Conservation and Open Space Policies

The City of Morgan Hill General Plan contains many policies supporting habitat conservation and preservation. The following policies are just a few examples taken from the Open Space and Conservation element of the general plan (City of Morgan Hill 2001a, 2001b, 2006).

**1a.** Work with the County, the Santa Clara Valley Open Space Authority, appropriate conservancy organizations and land trusts, and property owners to preserve large open space areas, such as agricultural lands and outdoor recreation areas to conserve natural resources, retain the city's unique identity.

**1b.** Support agricultural uses that can preserve open space.

**1c.** Preserve and maintain the wide variety of open spaces in the South County. Greenbelts should delineate and provide contrast between the city and adjacent urban areas. A system of city and regional parks should be linked by pedestrian ways, trails, and streamside parks. (South County Joint Area Plan [SCJAP] 16.00.)

**5a.** Encourage reclamation of degraded streams and riparian areas.

**5b.** Maintain riparian systems, stream banks and floodways in open space or related open space uses such as wildlife habitat, recreation or agriculture. (SCJAP 16.10.)

**5c.** A proposed streamside park along West Little Llagas Creek should be actively implemented and connected to the County trail system. (SCJAP 16.10 & 16.12.)

**5d.** Retain natural streamside and riparian areas in their natural state in order to preserve their value as percolation and recharge areas, natural habitat, scenic resources, recreation corridors and for bank stabilization. (SCJAP 15.08.)

**5e.** Where flood control projects are needed to protect existing development, minimize disruption of streams and riparian systems, maintaining slow flow and stable banks through design and other appropriate mitigation measures. (SCJAP 15.08.)

**6a.** Preserve all fish and wildlife habitats in their natural state whenever possible. Consider development impacts upon wildlife and utilize actions to mitigate those environmental impacts.

The City of Morgan Hill also adopted in 2003 and is now implementing a habitat mitigation plan for the western burrowing owl (City of Morgan Hill 2003). To

date, Morgan Hill has preserved one approximately 30-acre site to provide suitable habitat for burrowing owl (Live Oak Associates 2006).

## San José

San José, founded in 1777, was California's first civilian settlement. San José is located in the North Valley, on the eastern side of the Valley and adjacent to the southern tip of the San Francisco Bay. San José is by far the largest city in Santa Clara County, the third largest city in California (after Los Angeles and San Diego), and the tenth largest city in the United States.

Most of the City of San José lies within the study area. Approximately 9% of the city (10,543 acres) is excluded from the study area. (See Chapter 1 for a discussion of how the study area was defined.) Land use in San José is varied and includes a large urban core, as well as approximately 13,780 acres (12% of the incorporated city) of non-urban hillside.

The City of San José 2040 General Plan identifies several "Major Strategies" that represent central themes of planning in the City through 2040. The Greenline/Urban Growth Boundary Major Strategy is directed at preserving the scenic backdrop of the hillsides surrounding San José, preserving land that protects water, habitat, or agricultural resources, and offers recreational opportunities (City of San José 2011).

The City adopted Measure K, the establishment of the Greenline/Urban Growth Boundary, in 2000 with over 81% of voter support. The stated intention of the ballot measure was to develop a clearer geographic identity for San José as well as to preserve valuable open space resources. This line is the anticipated ultimate boundary of urban growth for San José, and the city has several policies in place that would prohibit the expansion of the Greenline/Urban Growth Boundary. As a requirement of the 2000 ballot measure, the boundary may only be repealed or amended by the voters of the City of San José (M. Mena pers. comm.). Therefore, the City's Greenline/Urban Growth Boundary will be used to represent the City's planning limit of urban growth for this Plan.

The City of San José adopted the *Envision San José 2040 General Plan* in November 2011. The revisions do not include an expansion of the Greenline/Urban Growth Boundary.

## Population, Housing, and Employment

The population of San José was 985,000 people in 2005 and is projected to reach 1,196,900 in 2020 and 1,339,400 in 2030, an increase of 22% and 36% over 2005 values, respectively.

Households in San José numbered 309,020 in 2005. The number of households is projected to reach 370,620 in 2020 and 417,790 in 2030, an increase of 20% and 35% over 2005 levels, respectively.

Jobs in San José numbered 375,750, or 36% of jobs Countywide, in 2005. The number of jobs is projected to reach 514,220 in 2020 and 617,790 in 2030, 44% and 46% of projected jobs Countywide, respectively (Association of Bay Area Governments 2005).

## **Conservation and Open Space Policies**

The City of San José has adopted several policies related to the Greenline/Urban Growth Boundary, controlled growth, and protection and conservation of open space. A selection of these policies from the general plan is listed below (City of San José 2011).

- The Greenline/Urban Growth Boundary establishes the maximum extent of urban development. All urban and suburban development should occur within the Greenline/Urban boundary. Areas outside of this boundary are intended to remain permanently rural in character and to contribute to the establishment of a permanent green belt along the City's eastern and southern edges (pp.6-29).
- Prohibit significant modifications of the Greenline/Urban Growth Boundary, as defined by Title 18 of the municipal code, except through a Major General Plan Update process (pp. 6-29).
- Design development at the urban/natural community interface of the Greenline/ Urban Growth Boundary to minimize the length of the shared boundary between urban development and natural areas by clustering and locating new development close to existing development (pp. 3-31).
- Minimize grading on hillsides and design any necessary grading or recontouring to preserve the natural character of the hills and to minimize the removal of significant vegetation, especially native trees such as Valley oaks (pp. 6-26).
- Encourage the preservation of hillside vegetation and require appropriate revegetation and planting of non-invasive plant materials that do not require routine irrigation for projects in hillside areas, if existing vegetation must be removed or substantially disturbed (pp. 6-28).

### **Riparian Corridors (pp. 3-27)**

- Preserve, protect, and restore the City's riparian resources in an environmentally responsible manner to protect them for habitat value and recreational purposes.
- New public and private development adjacent to riparian corridors should be consistent with the provisions of the Riparian Corridor Policy Study and any adopted Santa Clara Valley Habitat Conservation Plan/ Natural Communities Conservation Plan.

- Ensure that a 100-foot setback from riparian habitat is the standard to be achieved in all but a limited number of instances, only where no significant environmental impacts would occur.
- New development should be designed to protect adjacent riparian corridors from encroachment of lighting, exotic landscaping, noise and toxic substances into the riparian zone.
- The City encourages appropriate native plant restoration projects along riparian corridors, upland wetlands, and in adjacent upland areas.
- Develop a City Council Policy based on the City's Riparian Corridor Policy Study and HCP/NCCP to successfully implement the riparian goals and policies of the *Envision General Plan*, which recognizes that a 100-foot setback is the standard to be achieved in all but a limited number of instances, where no significant environmental impacts would occur.

## Contemplates Adoption of HCP

The *Envision San José 2040 General Plan* also specifically contemplates the adoption of the Habitat Plan and incorporates the goals of the Habitat Plan as follows.

- A long-range plan to protect and enhance ecological diversity and function within a large section of Santa Clara County, while allowing for currently planned development and growth.
- Providing a framework for the protection of natural resources while streamlining and improving the environmental permitting process for both private and public development, including activities such as road, water, and other infrastructure construction and maintenance work.
- Providing environmental benefit resulting in the creation of a number of new habitat reserves larger in scale and more ecologically valuable than the fragmented, piecemeal habitats yielded by mitigating projects on an individual basis,

The San José 2040 General Plan further contemplates the adoption of the Habitat Plan and includes specific strategies to further the goals of the Habitat Plan by:

- Shaping growth in the City to minimize impacts on resource consumption, reduce contribution to global warming, and to preserve and enhance its natural environment (pp. 1-22, Major Strategy #7 – Measurable Sustainability/Environmental Stewardship.)
- Implementing the Habitat Plan to mitigate for land and stream development impacts and provide additional conservation, restoration, and enhancement efforts (pp. 3-27, ER-1.8).
- Ensuring that new public and private development adjacent to riparian corridors in San José are consistent with the Habitat Plan (pp. 3-27, 28).
- Locating trail right-of-ways consistent with the provisions of the Habitat Plan (pp. 4-54 PR-7.2).

- Including public and private habitat conservation as an authorized land use in the “Open Hillside” land use designation (pp. 5-18).
- Considering habitat conservation objectives as part of hillside development proposals (pp. 6-28, LU-17.7).
- Retaining the City’s urban growth boundary to limit urban development in order to, among other purposes, preserve as open space substantial areas of surrounding hillsides, baylands, and other lands to conserve natural resources (pp. 6-29-35, “Land Use Policies – Non-Urban Areas”).

## Unincorporated Areas of Santa Clara County

Approximately 77% of the study area—398,250 acres—is in unincorporated areas of Santa Clara County. Existing development within the unincorporated area is concentrated in the small community of San Martin, located between Morgan Hill and Gilroy, and in the foothills adjacent to either side of the Santa Clara Valley. Other unincorporated communities and development areas in the County include New Almaden in San José’s South Almaden Valley urban reserve, Paradise Valley at the east end of Chesbro Reservoir, and along SR 152. In addition, small “pockets” of unincorporated urban areas exist within the urban service areas of San José and to a smaller extent, Morgan Hill and Gilroy.

Most of the County’s cultivated agricultural land is located along the floor of the South Valley, outside of the urbanized areas. Economically, agriculture is a small component of the County’s economy. The importance of agriculture relates primarily to the amount of land used for agricultural activities. Currently in Santa Clara County, approximately 20,900 acres are in irrigated agriculture; 87% of this agriculture is in unincorporated areas of the County, while 13% is in incorporated areas. Nearly all of this land is within the Plan study area. In addition to irrigated land, significant parts of the study area have historically been grazed by cattle and managed by ranchers. Cattle ranching continues over much of the lands in the study area, including on some public lands.

While some agriculture is located within cities, the majority of agricultural areas are located in the unincorporated County. Existing agricultural uses include bushberries and strawberries, field crops, floral crops (e.g., cut flowers), forest products, fruits and nuts (including grapes for wine making), livestock and poultry, milk and eggs, nursery crops, seed crops, and vegetable crops (County of Santa Clara, Division of Agriculture 2005). Range that is grazed constitutes the largest agricultural use. The Santa Clara County Division of Agriculture provides annual reports on the amount of acreage annually used for agriculture as well as the value of each crop in the County. Crops vary from year to year with the level at which a given crop is produced influenced by the annual value of the crop.

Ranchland and woodland land uses comprise a significant portion of the unincorporated portion of the County (approximately 49% of the entire County). Rangeland is generally located in the hills east and west of developed areas of the North and South Valleys.

The County of Santa Clara regulates land development within unincorporated areas (i.e., those areas in the County not under jurisdiction of any city). The County has not adopted any growth boundaries within its jurisdiction (R. Aggarwal pers. comm.). However, it does have policies and zoning which restrict denser development in the unincorporated areas (see *Conservation and Open Space Policies* section below).

## Population, Housing, and Employment

The population of the unincorporated areas of the County was 15,400 people in 2005 and is projected to reach 16,600 in 2020 and 16,900 in 2030, an increase of 8% and 10% over 2005 values, respectively.

Households in the unincorporated County numbered 5,260 in 2005. The number of households is projected to reach 5,500 in 2020 and 5,600 in 2030, an increase of 5% and 6% over 2005 values, respectively.

Jobs in the unincorporated County numbered 2,590, or 0.2% of jobs Countywide, in 2005. The number of jobs is projected to reach 3,120 in 2020 and 3,180 in 2030, 0.3% and 0.2% of projected jobs Countywide, respectively (Association of Bay Area Governments 2005).

## Conservation and Open Space Policies

The County developed its current general plan in 1995 and updated it in 2001. The County of Santa Clara, Parks and Recreation Department (County Parks) developed the *Strategic Plan for the Santa Clara County Parks and Recreation System* (County Parks Strategic Plan) in 2003 (County of Santa Clara, Parks and Recreation Department 2003). A selection of general plan and County Park Strategic Plan policies related to conservation and open space is listed below (County of Santa Clara 1994; County of Santa Clara, Parks and Recreation Department 2003).

### County General Plan

**R-PR 3<sup>2</sup>.** The County's regional park system should:

- a. utilize the county's finest natural resources in meeting park and open space needs; and
- b. provide a balance of types of regional parks with a balanced geographical distribution.

**R-RC 37.** Lands near creeks, streams, and freshwater marshes shall be considered to be in a protected buffer area, consisting of the following:

- 1. 150 feet from the top bank on both sides where the creek or stream is predominantly in its natural state;

<sup>2</sup> Policy labels are from the County or city document in which the policy is identified.

**2.** 100 feet from the top bank on both sides of the waterway where the creek or stream has had major alterations; and

**3.** In the case that neither (1) nor (2) are applicable, an area sufficient to protect the stream environment from adverse impacts of adjacent development, including impacts upon habitat, from sedimentation, biochemical, thermal and aesthetic impacts.

**R-RC 38.** Within the aforementioned buffer areas, the following restrictions and requirements shall apply to public projects, residential subdivisions, and other private non-residential development:

**a.** No building, structure or parking lots are allowed, exceptions being those minor structures required as part of flood control projects.

**b.** No despoiling or polluting actions shall be allowed, including grubbing, clearing, unrestricted grazing, tree cutting, grading, or debris or organic waste disposal, except for actions such as those necessary for fire suppression, maintenance of flood control channels, or removal of dead or diseased vegetation, so long as it will not adversely impact habitat value.

**c.** Endangered plant and animal species shall be protected within the area.

**R-RC 47.** Impacts from new development on woodland habitats should be minimized by encouraging:

**a.** clustering of development to avoid critical habitat areas, where clustering is permitted;

**b.** inclusion of important habitat within open space areas for project requiring open space dedication;

**c.** siting and design of roads, utility corridors and other infrastructure to avoid fragmentation of habitat; and

**d.** acquisition or avoidance of critical habitat areas.

**R-RC 95.** The scenic and aesthetic qualities of both the natural and built environments should be preserved and enhanced for their importance to the overall quality of life for Santa Clara County.

**R-RC 96.** The general approach to scenic resource preservation for the rural unincorporated areas consists of the following strategies:

**1.** Minimize scenic impacts in rural areas through control of allowable development densities.

**2.** Limit development impacts on highly significant scenic resources, such as, ridgelines, prominent hillsides, streams, transportation corridors and county entranceways.

**R-LU 25.** Non-residential land uses allowed in 'Hillsides' areas shall be of a generally low density or low intensity nature, depending on the use, as is consistent with the basic intent of the Hillsides designation to preserve the resources and rural character of the land.

**R-LU 59.** Residential development may be clustered, provided that the open space portions of the development are protected as permanent open space.

**R-LU 20.** Proposed cluster residential developments shall adhere to the following:

- 2. Open Space:** it is mandatory that no less than 90% of the land area shall be preserved permanently as open space through dedication of an open space or conservation easement precluding any future development:
  - a.** those portions of the land permanently preserved as open space shall be configured as large, contiguous and usable areas;
  - b.** the open space may be dedicated through easements over portions of individually-owned parcels or may be configured as separate parcels owned in common or individually;
  - c.** the open space area shall be privately controlled and not accessible to the public unless the area is deeded to a public agency or entity willing to undertake responsibilities of ownership, maintenance, and public access [designated trail corridors may traverse such areas if proposed as part of the Regional Parks, Trails, and Scenic Highways Plan]; and
  - d.** land uses allowed within the area dedicated as permanent open space shall be limited to agricultural or other limited resource-related uses, and to non-commercial recreational facilities of an ancillary nature to the cluster residential development and for use by residents only.

### County Parks Strategic Plan

**Strategy #1.1.1:** Acquire New Parks – New regional park acquisitions should be considered on lands that:

- expand the boundaries of existing parks or connect these areas;
- provide parks in underserved areas; and
- conserve representative diverse natural landscapes and historic resources of the County.

**Strategy #4.1.1:** A regional parks and trails system should be designed that is consistent with the County General Plan and other County policies associated with protecting and enhancing natural resources, including but not limited to: rich biological habitat areas including wetlands, baylands, and riparian areas; areas of serpentine geology; natural, cultural, and historic areas; and other significant natural features.

**Strategy #4.1.2:** Park and trail use levels and a monitoring system should be developed to ensure recreation and biological resources are balanced in a manner that protects resource qualities.

**Strategy #4.1.3:** Recreational uses and facilities should be planned and located on suitable lands to avoid impacts to rich biological habitat areas.

**Strategy #4.1.4:** When park development might impact natural areas, appropriate mitigation to enhance/improve the habitat values should be employed.

**Strategy #4.3.1:** Natural habitat areas in the County Parks should be enhanced through active stewardship programs and using best management practices (BMPs) based on the most current, reliable scientific information available.

## San Martin Planning Area

San Martin is an approximately 12.3-square-mile unincorporated community located between the sphere of influence lines of the cities of Morgan Hill and Gilroy. San Martin is a rural residential community built around a village dating back to the early 1900s. This community, surrounded by farms, orchards and ranchlands, retains a pastoral rural character (County of Santa Clara 1994). As of the 2000 census, San Martin had a total population of 4,230 (U.S. Census Bureau 2006).

The Santa Clara County General Plan anticipates that this area will remain rural residential. However, there is concern within the San Martin community that local land use control will be diminished as housing pressure for the growing County population increases.

### Relevant General Plan Policies for San Martin

**R-LU 114.** San Martin should be viewed as a distinct entity, containing unique rural characteristics. Care should be taken to prevent premature commitment of land for uses that would restrict future options for the community.

## Santa Clara Valley Water District

SCVWD is the primary water resource agency for Santa Clara County (Santa Clara Valley Water District 2006), providing water to the residents and businesses of Santa Clara County as a water wholesaler and managing local groundwater. SCVWD is also a flood-protection agency and is the main steward for urban streams and creeks in the County and its underground aquifers. Stewardship activities include creek restoration and wildlife habitat projects, pollution prevention, and a commitment to natural flood protection (Santa Clara Valley Water District 2006).

The mission of SCVWD is to maintain “a healthy, safe, and enhanced quality of living in Santa Clara County through watershed stewardship and comprehensive management of water resources in a practical, cost-effective, and environmentally sensitive manner” (Santa Clara Valley Water District 2006). This mission reflects the current approach to water management utilized by SCVWD that balances water supply, flood protection, and environmental sensitivity. SCVWD has developed several programs including the Stream Maintenance Program and Watershed Stewardship Program that also reflect this management approach.

There are 768 miles of creeks with watersheds greater than 320 acres. SCVWD owns 178 miles or 26% of these creeks; other public agencies own 87 miles or 19% of the creeks; private owners own 400 miles or 52% of the creeks and the remaining 46 miles or 6% of the creeks are owned by unidentified entities. SCVWD holds easements on approximately 100 miles of creeks which are owned in fee title by others.

SCVWD is a conjunctive-use agency. Conjunctive use is a system of water supply management that utilizes both aboveground (reservoir) and below-ground (aquifer) storage facilities to ensure water supply reliability. Conjunctive use typically entails reservoir or pipeline releases to groundwater recharge ponds—which are either on-channel (i.e., in a natural stream bed) or off-channel—where water percolates into an aquifer and is stored for later extraction. Water stored this way may be rainfall collected in the reservoirs in the County, or reclaimed water. In addition to local water resources, SCVWD also imports water from the State Water Project and the Central Valley Pipeline. SCVWD’s conjunctive use strategy involves managing the available water supplies and the water supply system to:

- meet on-going demand for water from a variety of local and imported sources;
- fill reservoirs in the wet season; and
- transfer water from reservoirs to underground storage in the dry season, making room in the reservoirs for the next wet season.

In order to ensure water will always be available to meet flow requirements and water supply needs, SCVWD utilizes a network of reservoirs, pipelines, and canals to transfer water into the county and also between watersheds within the study area. Imported water (State Water Project and Central Valley Project) enters the county via pipelines and is either deposited in reservoirs, recharge ponds, canals, or into local stream channels. Water transfers between reservoirs are facilitated by pipelines and canals. The canals were built to transport water between creek systems, from creeks to percolation ponds, and to generally support the management of water supply resources in the Valley. They also assist with stormwater management, helping to drain high flows. Water extracted from the system for use is directed to water treatment plants via pipelines and pumping stations.

Operating such a system requires detailed timing of flow releases from reservoirs, management of imported water, operation of in-channel facilities and canals, operation of pumping stations, and maintenance of the infrastructure required to support the system. It also requires maintenance of a complex system of water supply pipelines, canals, dams, reservoirs, pumping stations, diversions, drop structures, streamflow gauges, fish ladders, fish screens, water treatment plants, canals, and associated facilities. An overview of SCVWD water conveyance, treatment, and distribution system is shown in **Figure 2-1**.

SCVWD owns and operates ten reservoirs, with a main function of providing water supply and a secondary function of providing flood control. The reservoirs

also serve a tertiary need for recreation. Only one reservoir, Chesbro Reservoir, was designed as a multipurpose facility with a dedicated flood-storage level and an outlet that can significantly reduce storage in a short time (Santa Clara Valley Water District 2005). Eight of the ten reservoirs are located in the study area: Vasona, Guadalupe, Almaden, Calero, Anderson, Coyote, Chesbro, and Uvas reservoirs (see **Figure 1-2** for a study area map that includes reservoirs). The remaining two reservoirs, Stevens Creek and Lexington Reservoirs, are outside the study area.

SCVWD is responsible for inspection; operations; and maintenance, repair, and replacement of facilities on properties it owns or for which it holds an easement. SCVWD is also responsible for operations and maintenance of the San Felipe Division facilities that are owned by the Bureau of Reclamation. These properties and easements account for approximately 35% of the total creek and canal length in the county, including the Coyote, Almaden-Calero, and Coyote-Alamitos canals and the Coyote canal extension.

## Factors Affecting Conjunctive Use Operations

Factors influencing how water supply is managed vary over time and by site, depending on the time of year, availability of water supply from outside sources, SCVWD's legally defined rights to water supplies from each source, conditions at each site, the local demand for water, and the condition and operability of SCVWD facilities. Factors that affect reservoir operation include water rights, water contracts, safety, recharge and fish flows, facility maintenance, climactic variation, and the California Division of Safety of Dams (DSOD) interim storage or other restrictions. Each of these factors is described below. Conjunctive use operations are affected by the factors described below.

### Water Rights

SCVWD holds water right licenses and a permit from the State Water Resources Control Board to appropriate a specified maximum volume of water for storage in any given year. In terms of on-the-ground operations, the right to appropriate water at a reservoir is effectively the right to divert or capture this water behind the dam and store it to provide for some beneficial use. These diversions are generally limited to the wet season, generally defined as October 1 through April 30. However the authorized diversion period for each water right varies. During periods when SCVWD does not have authorization to divert at the reservoirs (generally May 1 through October 30), SCVWD must release flow at the rate of inflow to the reservoir. For example, if inflow to a reservoir outside of the authorized diversion period is two cubic feet per second (cfs), then SCVWD must release at least 2 cfs, and it cannot divert this flow downstream. However, if SCVWD releases water from storage, that is water in excess of the natural inflow, SCVWD may release that water for recharge, either in-stream or by diversion to off-stream facilities, or release the water for other SCVWD purposes.

SCVWD has water rights to divert natural inflow at the site of its off-channel recharge facilities. These rights specify a total annual volume that may be

diverted and a diversion period. In addition to limitations imposed on SCVWD's diversions to storage imposed by its water rights and the design of diversion dams, diversions are also governed by the capacity of fish screens, CDFG bypass flow requirements, and placement of flashboards.

### **Water Contracts**

SCVWD has two primary water supply contracts: one with DWR for 100,000 acre-feet from the State Water Project and one with the Bureau of Reclamation for 152,500 acre-feet from the Central Valley Project. The combined water supply contracts provide a total of 252,500 acre-feet to SCVWD annually. Both contract supplies are subject to annual shortages, and both provide access in wet years to additional temporary deliveries. To improve long-term reliability, SCVWD also has a contract with Semitropic Water Storage District (Semitropic) for 350,000 acre-feet of banking capacity, and enters into a variety of imported water management contracts, including annual, short-term, and long-term water exchange, transfer, sale, conveyance, and management agreements with various parties. New contracts and contract renewals and amendments are for the purpose of improved reliability and, when combined with the allocation under each of the Central Valley Project and State Water Project contracts, would not exceed a maximum annual delivery of 252,500 acre-feet to Santa Clara County over the course of the permit term of this Plan. Because the amount of imported water is not anticipated to increase over existing planned water imports, and population growth according to existing general plans is covered (described in Section 2.3.2 *Urban Development*), this Plan covers any direct, indirect, cumulative, or growth-inducing effects of delivering and utilizing imported water under existing and future contracts if the amounts and points of delivery remain as projected.

Delivery of imported water by the Department of Water Resources and the Bureau of Reclamation to SCVWD's service area and contract renewal between SCVWD and the Bureau of Reclamation is not a covered activity under this Plan. However, this Plan does cover the reconstruction of facilities located within the permit area (described below in Section 2.3.3 *In-Stream Capital Projects* and Section 2.3.5 *Rural Capital Projects*) required to transport imported water throughout the study area (e.g., reservoirs, canals, groundwater recharge ponds), and the operation and maintenance of facilities located within the permit area (described in this section and in Section 2.3.6 *Rural Operations and Maintenance*) required to manage water supply (e.g., Dam Maintenance Program, reservoir operations, recharge operations, Pipeline Maintenance Program).

### **Safety**

Reservoirs also function to reduce the potential for very large storms to cause flooding, and operators may slow down the rate of reservoir filling or make post-storm releases to avoid having a full reservoir too early in the wet season. To the extent that it is feasible, SCVWD operates to ensure that there is appropriate "space" in the reservoir to store anticipated storm flows and monitors weather on an on-going basis; releases may be made prior to a storm if needed to ensure adequate storage space. Following a storm, SCVWD may make additional releases to restore needed space for subsequent storm flows. As a result,

reservoir operations in the wet season are not characterized by a steady increase in storage, but by episodes of storage and release of water, with a general trend towards increasing the volume of water stored as the wet season progresses.

### **Fish Flows**

SCVWD maintains flow in the channels using local and imported water supplies to maintain fish and wildlife habitat below the dams. In order to benefit the fisheries within the watersheds in which SCVWD's conjunctive use water supply operations take place, SCVWD may re-operate its conjunctive use operations (i.e., alter how conjunctive use operations are currently managed in order to further enhance fish habitat). This re-operation is described in this chapter under the *Proposed Three Creeks HCP Conservation Program Operations and Maintenance Actions* and *Proposed Operating Rules for Water Supply Facilities in the Uvas and Llagas Watersheds*. Such re-operation may alter the existing pattern of storage and recharge which may result in take of covered amphibians and reptiles.

SCVWD will not re-operate its conjunctive use operations until it receives authorization from NMFS and CDFG. In the proposed Three Creeks HCP study area this will be accomplished through the Three Creeks HCP. In the Uvas and Llagas watersheds, this may be accomplished through an informal consultation with NMFS and CDFG, a new HCP process, or through formal consultation with NMFS pursuant to Section 7 of the ESA.

### **Facility Maintenance**

Facility maintenance may require SCVWD to reduce reservoir releases temporarily. For example, recharge basins may require cleaning, and SCVWD would reduce diversions accordingly. At the dam, valves may need routine calibration and maintenance, resulting in short-term reductions in releases.

### **Climate Variation**

Groundwater recharge is possible in all seasons because of the intermittent nature of precipitation and inflow to the study area watersheds. For example, there are many times in a typical wet season when natural flow is minimal and SCVWD makes releases from reservoirs and other facilities to maintain a wetted channel and to provide for off-channel recharge. In addition to intra-annual variation in conditions, conjunctive use operations also respond to year-to-year conditions. In dry years, initial wet-season storage may be quite low, resulting in an initial period of limited releases as storage reaches the baseline values for seasonal storage. When this occurs, a more normal pattern of storage and release is implemented.

### **Flood Management**

In addition, the SCVWD will continue to operate its reservoirs to provide for safe conditions for downstream communities. This involves managing reservoir storage to ensure that there is adequate capacity to contain high levels of projected inflow during storm events. Reservoirs capture flood flows from the upper watershed and protect downstream reaches from overbanking. When a large storm is predicted, reservoir storage is drawn down to a level that allows room to capture upstream flood flows. SCVWD developed probability flood

curves which are used to determine how much flood storage room should be freed up. Prior to a major storm, SCVWD may increase releases to provide for storage adequate to prevent flooding, followed by a shift to reduce releases when the threat of flooding has passed.

## Water Resources Protection Ordinance

In October 2006, SCVWD enacted the Water Resources Protection Ordinance. This ordinance established the regulations by which, beginning on February 28, 2007, SCVWD issues permits for modifications, entry, use, or access to SCVWD facilities with the approval and enactment of ordinance O6-1, and where SCVWD has either a fee title or easement property right. This ordinance was developed and enacted to codify the Water Resources Protection Ordinance: Guidelines and Standards for Land Use Near Streams developed by the Santa Clara Valley Water Resources Protection Collaborative<sup>3</sup> (Collaborative).

The Collaborative was formed in 2003 to address the needs of flood management, drinking water quality and quantity, surface and groundwater quality and quantity, and habitat protection and enhancement throughout the county (Santa Clara Valley Water District 2006). With the enactment of these measures, SCVWD, the cities, and the County are better equipped to protect the integrity of streams in the context of the goals of cleaner, healthier, and more sustainable water resources.

Other agencies do not comply directly with ordinance O6-1, but instead can adopt the guidelines of O6-1 or determine that existing zoning code and/or policies fulfill the guidelines. San José and the County approved resolutions, finding that their existing codes comply with the guidelines, Morgan Hill adopted the guidelines, and Gilroy added a new Water Resources Protection chapter to its zoning code, thereby incorporating the guidelines. An encroachment permit is required for all projects that modify, enter, use, or access SCVWD lands and/or easements. It is through the administration and issuance of the encroachment permit that the guidelines and standard are enforced and tracked.

The issuance of the encroachment permit is subject to an environmental assessment and must be found to be in compliance with CEQA. In addition, a number of findings must be made, including, but not limited to, that the proposed modifications will not impede, restrict, slow down, pollute, change the direction of water flow, catch or collect debris carried by the water, and banks will not be damaged, weaken, eroded, increase siltation, be reduced in their effectiveness to withhold storm and flood waters.

---

<sup>3</sup> The Santa Clara Valley Water Resources Protection Collaborative is formed by several member agencies and private community members including SCVWD, the County of Santa Clara, all of the cities and towns within Santa Clara County.

## **Santa Clara Valley Transportation Authority**

The VTA is an independent special district responsible for bus and light rail operations, congestion management, specific highway improvement projects, and Countywide transportation planning. As such, VTA is both a transit provider and a multi-modal transportation planning organization involved with transit, highways and roadways, bikeways, and pedestrian facilities (Santa Clara Valley Transportation Authority 2006).

The mission of VTA is to provide “sustainable, accessible, community-focused, transportation options that are innovative, environmentally responsible, and promote the vitality of our region” (Santa Clara Valley Transportation Authority 2008).

The responsibilities of VTA include transit service, transit planning, highway planning, commuter train service (Caltrain), the Congestion Management Program, and regional transit partnerships. VTA is primarily a funding agency for local transportation and related projects such as bikeways.

VTA often partners or works in conjunction with other agencies and jurisdictions. A manifestation of this is apparent in the Valley Transportation Plan 2035 (VTP 2035) recently completed by VTA (Santa Clara Valley Transportation Authority 2009). This document contains hundreds of projects submitted to VTA by cities in Santa Clara County and by the County. Although these projects are spearheaded by the jurisdiction, the VTP 2035 helps the jurisdictions present the projects as part of a long-range planning package, as well as seek funding sources for the projects. Almost all projects in the VTP 2035 are projects that VTA will implement with other local or state agency partners.

### **2.2.2 Land Use Categories**

Understanding the future land use in the Plan study area is an important step in developing the impact analysis for covered activities in Chapter 4. The adopted general plans for the cities of Gilroy, Morgan Hill and San José and Santa Clara County were used to identify future extent and location of urban and rural development in the study area that could be covered by the Plan. General plan land use designations and discussions with the participating jurisdictions were used to refine the land use assumptions for the areas that are designated to become urban.

General plan land-use designations vary across jurisdictions and are generally in more categories than necessary for the Plan, so they need to be simplified and standardized. The process by which a land use map was developed and how land use categories for the Plan were assigned is described below.

## Methodology for Developing the Land Use Categories Map

Land-use designations for Santa Clara County and Cities of Gilroy, Morgan Hill, and San José were used to develop a single land use map for the Plan. Future land uses were assumed to be consistent with the general plans of the County (2001), City of Gilroy (2002a, 2002b), City of Morgan Hill (2006), City of San José (2006a, 2011), and the City of Gilroy Hecker Pass Specific Plan (City of Gilroy 2005b). The County of Santa Clara general plan projects future land use to 2010, the Gilroy general plan projects future land use to 2020, the Morgan Hill general plan includes growth and development management measures that extend to 2025, and the San José general plan projects land use to 2040. Using these projections for this Plan with a significantly longer time horizon is regarded as appropriate given the strength of each jurisdiction's commitment to constraining future growth within established urban growth boundaries (see discussion above under *Existing Conditions*).

Over 80 land-use designations from the four jurisdictions were aggregated into the following six categories.

- Urban Development.
- Rural Residential.
- Ranchland/Woodland.
- Agriculture.
- Urban Parks and Open Space.
- Rural Parks and Open Space.

Development of these six categories was guided by the nature of the covered activities within each land use category and their relative impact on biological resources. For example, the many urban land use categories (e.g., residential, commercial, industrial) were combined into a single land use category for this Plan because they all result in similar effects on biological resources. **Table 2-1** shows general plan land uses and the Plan land use categories to which they were converted.

Most of the jurisdictional land-use designations translate in their entirety to a Plan land use category. One exception, however, is parks and open space designations in each city. Some city parks are large, located on the urban fringe, and may function well as habitat for covered species or as a part of a movement corridor. In these cases, the park was designated as Rural Parks and Open Space. Therefore, city designations for parks and open space will be individually considered and certain sites will be categorized as Rural Parks and Open Space.

## Plan Land Use Categories

**Figure 2-2** shows the Plan land use categories in the study area. This map depicts development land use designations that include both developed and undeveloped areas (for actual land *cover*, see Chapter 3).

The Urban Development land use category includes residential densities greater than 1 dwelling unit per 2.5 acres, as well as all industrial, commercial, institutional, public facilities, public/quasi-public, and major educational facilities land-use designations. The study area is 519,506 acres of which 100,143 acres (19%) are categorized as Urban Development.

The Rural Residential category includes low-density residential development density of 1 dwelling unit per 2.6 to 20 acres. Rural residential lands tend to be located in the unincorporated areas of the County; however, each of the three cities covered by the Plan also maintain land use densities that correspond to the Plan's Rural Residential category. The Rural Residential land use category comprises 13,141 acres (3%) of the study area.

The Ranchland/Woodland category includes rural lands with a development density of 1 dwelling unit per 20.1 to 160 acres. This category is comprised of all lands not otherwise designated. It includes open lands common in the western slopes of the Diablo Range as well as the woodlands common to the eastern slopes of the Santa Cruz Mountains. According to the County general plan, ranchlands are defined as "lands predominantly used as ranches in rural unincorporated areas of the County, remote from urbanized areas and generally less accessible than other mountain lands." The Ranchland/Woodland land use category comprises 253,098 acres (49%) of the study area.

County lands designated as Agriculture may be used for: "agriculture and ancillary uses; uses necessary to directly support local agriculture; and other uses compatible with agriculture which clearly enhance the long term viability of local agriculture and agricultural lands" (County of Santa Clara 1994). In addition to the County, the City of Gilroy supports some agriculture in the Hecker Pass Special Use District and Specific Plan. Agriculture in this area includes low intensity crops such as vineyards, orchards, and some row crops (City of Gilroy 2005b). For this Plan, land uses identified by the Hecker Pass Specific Plan are incorporated with land-use designations of the City of Gilroy. The Agriculture land use category comprises 23,852 acres (5%) of the study area.

The Plan category of Urban Parks and Open Space includes lands designated by cities or the County for parks and recreation, and for open space that is surrounded by urban development or is itself highly developed or landscaped. These sites are all located within incorporated city limits and are unlikely to be used by any of the species covered by this Plan except along some rivers and creeks. The Urban Parks and Open Space land use category comprises 7,289 acres (1%) of the study area.

The Plan Rural Parks and Open Space category encompasses parks and open space in rural areas, including larger parcels of land located on the urban fringe,

and indicates that the landscape may be used by covered species. This category includes federal land; local, state, and regional parks; private lands that are protected with conservation easements or dedicated development rights, or that are used in a manner that would allow use by covered species (including large golf courses on the urban fringe); and public watershed lands. Some of the sites categorized as Rural Parks and Open Space are expected to be important components of the Plan conservation strategy. The Rural Parks and Open Space land use category comprises 121,072 acres (23%) of the study area.

### 2.2.3 Planning Limits of Urban Growth

Urban development covered by the Plan includes the growth anticipated by approved or drafted general plans at the time of permit issuance. Identifying the extent of expected urbanization within the Plan study area, or the “planning limit of urban growth,” informs the impact analysis and identifies the extent of take coverage for urban development needed under the Plan.

One important factor in identifying the planning limit of urban growth is defining where road projects enter and exit the urbanized area. Road projects outside urban areas are expected to have greater impacts on some covered species than road projects within urban areas, so they may be treated differently by the Plan. The anticipated planning limits of urban growth are discussed for each city under the Existing Conditions section above, are shown in **Figure 2-2**, and are summarized below.

- Gilroy: General Plan Boundary (City of Gilroy 2002a).
- Morgan Hill: Urban Limit Line (adopted April 2006).
- San José: Urban Growth Boundary, also known as the “Greenline” (adopted by voters in 2000).

There are three exceptions to the assumption of full urban development within the planning limits of urban growth over the course of the permit term.

1. The City of San José Coyote Valley Urban Reserve and the South Almaden Valley Urban Reserve.
2. The City of Morgan Hill Southeast Quadrant.
3. The City of Gilroy Hecker Pass Specific Plan (City of Gilroy 2005b).

These three areas are assumed to be developed consistent with rural development land uses and not urban land uses.

The County does not permit urban growth in its jurisdictions except within urban “pockets” of unincorporated lands that occur in small patches within the three cities. The County has identified a general plan Strategy of promoting eventual annexation of these urban pockets to the city in which the pocket is located (County of Santa Clara 1994). Therefore, it is anticipated that all County pockets currently inside a city’s planning limit of urban growth will be incorporated into

a city over the course of the permit term of the Plan. As such, a planning limit of urban growth is not defined for the County in this Plan.

## 2.2.4 Existing Open Space and Parkland

Dating back to the 1970s, the County of Santa Clara, SCVWD, and the cities of Gilroy, Morgan Hill, and San José have had a close connection to the natural landscapes of the Santa Clara Valley and an awareness of the importance of protecting open space. Of the 519,506-acre study area, 151,727 acres (29%) are currently protected as open space of some kind. These areas range from urban parks to County and state parks of varying size. The following section provides an overview of existing open space agencies with holdings in the study area and the major open space units that they operate. Significant open space units in the study area which help support the Plan's conservation strategy are described in **Table 2-2** and shown in **Figure 2-3**.

### United States Bureau of Land Management

The Bureau of Land Management owns several parcels of land in Santa Clara County. Two of those parcels are located within the study area just north of Middle Fork of Coyote Creek, north of Henry W. Coe State Park. The Bureau of Land Management has transferred large parcels of land to California Department of Parks and Recreation (State Parks) to become part of Henry W. Coe State Park. The remaining parcels totaling approximately 1,025 acres are still under the ownership of the Bureau of Land Management, but may be transferred to the park in the future.

### California Department of Parks and Recreation

State Parks owns two large parks that occur, in part, in the study area: Henry W. Coe State Park and Pacheco State Park. State Parks also jointly owns Martial Cottle Park with the County of Santa Clara. Henry W. Coe State Park and Pacheco State Park are discussed below. Martial Cottle Park is discussed under *County of Santa Clara, Parks and Recreation Department*.

#### Henry W. Coe State Park

Henry W. Coe State Park is the largest state park in northern California at 85,843 acres, 58,642 acres of which (68%) are within the study area. The remaining 27,201 acres of the park are in Santa Clara and Stanislaus Counties. Much of the park was originally donated by Sada Coe Robinson to Santa Clara County in 1953, when it became Henry Willard Coe County Park. In 1958, the park was added to the state park system. The park's original size was approximately 13,000 acres. Since the 1980s, the park has expanded

considerably through the purchase of adjacent properties on all sides. The park is still growing.

Elevations in this rugged park range from approximately 1,000 feet to 3,560 feet. The park has a diverse mix of habitat types including grassland, oak woodland, ponderosa pine forest, mixed chaparral, riparian woodland, and over 100 ponds. The park also supports two large man-made lakes, Mississippi Lake and Coit Lake, as well as the headwaters of Coyote Creek and several miles of Pacheco and Orestimba creeks. The 23,300-acre Orestimba Wilderness, a state-designated wilderness area that accounts for approximately 27% of the total acreage of the park, is entirely within Stanislaus County, adjacent to the study area. The park is open year-round for hikers, mountain bikers, backpackers, equestrians, picnickers, and photographers on over 100 miles of trails and roads. Access to the park by car is extremely limited, with only four entrances and paved roads that stop at the margins of the park. The main entrance and park headquarters is approximately 13 miles east of U.S. 101 northeast of Gilroy and accessed via the Dunne Avenue exit from U.S. 101 in Morgan Hill (California Department of Parks and Recreation 2004).

Natural resources management at Henry W. Coe State Park is focused on high-priority threats, such as an overabundance of wild pigs, which can cause considerable damage to wetland and grassland areas. To address this threat, park managers contract with trained hunters to help reduce wild pig populations. Yellow star-thistle and other invasive weeds also present a threat to the native grasslands in the park. Grassland areas are managed through the use of small prescribed burns which reduce the spread of invasive plant species. An important unmet need in park management is maintenance of existing but unused stock ponds that provide important habitat for California red-legged frog and California tiger salamander (A. Palkovic pers. comm.). There is no livestock grazing in the park. Wildfire management is also an issue for the park. In 2007, the Lick fire burned 47,760 acres and resulted in a temporary closure of affected areas in the park. Currently there are fewer than three full-time staff devoted to this park. Staff and budget limitations severely constrain State Park's ability to conduct extensive habitat and species management in this large park.

## **Pacheco State Park**

Pacheco State Park came into existence through a donation in 1992 by Paula Fatjo, a direct descendant of Francisco Pacheco for whom the Pacheco Pass is named. Visitors on the park's trails enjoy views of the San Luis Reservoir and the San Joaquin Valley to the east and views of the Santa Clara Valley to the west. The park supports rolling hills of mostly grassland and oak woodland habitats. Approximately 734 acres of the 6,921-acre park are within the study area. The remaining 6,187 acres are in adjacent Merced County. The western 2,600 acres of the park (including the portion in Santa Clara County) are open to the public (California Department of Parks and Recreation 2004).

## California Department of Fish and Game

The CDFG owns the Cañada de los Osos Ecological Area, formerly the Stevenson Ranch, located on Jamieson Road, about ten miles east of Gilroy. The CDFG purchased the 4,400-acre ranch in 2001 with the assistance of The Nature Conservancy. Two hundred acres of the property were sold to the State Parks as a trailhead into Henry W. Coe State Park. The remaining 4,200 acres are managed by the CDFG in cooperation with the California Deer Association for youth outdoor education programs and the improvement of wildlife habitat on the property. A grazing management plan has been developed for this site, although the plan has not been implemented.

## County of Santa Clara, Parks and Recreation Department

The mission of County Parks is to provide, protect and preserve regional parklands for the enjoyment, education and inspiration of this and future generations (County of Santa Clara, Parks and Recreation Department 2003). Since its inception in 1956, County Parks' park system has grown to encompass approximately 45,000<sup>4</sup> acres in 28 park units that provide a variety of urban and rural recreational amenities. For more than four decades, County Parks has focused on purchasing and developing a network of regional parks and trails along the hillsides adjacent to the urban fringe and along the creeks that pass through the urban service area. This "necklace of parks" vision was put into place in the early 1960s and has guided park acquisition and development ever since (County of Santa Clara, Parks and Recreation Department 2003). County Parks balances access and recreation with resource protection. In addition to providing recreation opportunities in the County, County Parks conducts resource preservation, protection, conservation, enhancement, and restoration.

### Strategic Plan

With the goal of accommodating the growing outdoor recreation needs of an increasing urban population, the County Parks Strategic Plan (County of Santa Clara, Parks and Recreation Department 2003) lays out a vision that will allow the system to continue to meet the needs of the County's residents. The vision of the Plan is captured in the following statement.

We create a growing and diverse system of regional parks, trails, and open spaces of Countywide significance that connects people with the natural environment, offers visitor experiences that renew the human spirit, and balances recreation opportunities with resource protection (County of Santa Clara, Parks and Recreation Department 2003).

---

<sup>4</sup> While County Parks manages all 45,000 acres for recreation, approximately 5,000 of the 45,000 acres are owned by SCVWD.

The County Parks Strategic Plan focuses on the balance of recreation and natural resource protection, guiding the improvement and expansion of the County park and countywide trail system to meet the growing demand for high-quality recreational opportunities in Santa Clara County while also supporting and protecting local natural resources (County of Santa Clara, Parks and Recreation Department 2003).

## **Countywide Trails Master Plan**

The Santa Clara County Countywide Trails Master Plan Update, an update to the 1980 County General Plan Trails element, was completed in November 1995 by the County of Santa Clara, Parks and Recreation Department. The Board of Supervisors adopted the updated trail policies and trails map as an amendment to the County General Plan. This update provides a vision for a network of contiguous trails that connects County parks, open space areas and other trails systems with northern and southern urbanized areas. As part of the update, the countywide trails policies and design guidelines were updated and developed to guide continued planning, define a process for implementing trails and coordinating with private property owners, establishing priorities, mitigating environmental impacts, and directing trail use, design, operations, and management (County of Santa Clara, Parks and Recreation Department 1995).

## **Natural Resources Management**

County Parks maintains a small but active natural resources management program guided by the County Parks Strategic Plan and natural resources management guidelines (County of Santa Clara, Parks and Recreation Department 2004). The Natural Resources Management Program is comprised of four full-time staff for the entire County park system. Management or restoration projects are often implemented by natural resource staff, park maintenance staff, park rangers or contractors.

County Parks is in the process of developing comprehensive natural resource management plans for all of its park units and grazing management plans for some of its park units. The Ed R. Levin, Joseph D. Grant, and Coyote Lake-Harvey Bear Ranch County parks were the first County parks for which County Parks developed formal natural resource management plans in the study area. The Coyote Creek Parkway Integrated Master Plan (a combined natural resource management plan and master plan) was adopted in March 2007 (County of Santa Clara, Parks and Recreation Department 2006a). Interim natural resource management plans have been completed for most of the parks.

The current focus of the natural resources management program is conducting system-wide assessments of resources within the parks to identify and prioritize management actions. Site-specific management projects have been limited due to funding and staffing constraints and the need for management plans. Recent projects and programs have included riparian enhancement, invasive weed

control, oak woodland enhancement programs, vegetation management projects and programs, grassland enhancements, wildlife enhancements throughout the park system, livestock grazing programs, wetland restoration, and prescribed burns. Many of these actions have taken place at Joseph D. Grant County Park.

In 2004 a Grazing Management Plan was completed for Calero/Canada del Oro to address Bay checkerspot butterfly mitigation and habitat enhancement. In 2011 County Parks completed a Grazing Management Plan for Santa Teresa County Park to address management of annual grasslands and oak woodlands for the benefit of native species, management of wildfire risks, control of non-native plant species, while addressing continuing public access to these special areas. This Grazing Management Plan is in response to the need to manage serpentine grassland habitats as well as the implementation of the USFWS's *Recovery Plan for Serpentine Species of the San Francisco Bay Area* (U.S. Fish and Wildlife Service 1998). Through federal grant funding assistance from the USFWS and the Bureau of Reclamation, County Parks will be implementing the goals of the Grazing Management Plan to return cattle to the park in order to manage the serpentine grassland habitats.

## Major County Parks

Several large regional parks within the study area are owned and/or managed by County Parks. Collectively, these parks are representative of the diverse resources available in Santa Clara County and support a variety of recreational interests including hiking, mountain bicycling, horseback riding, picnicking, golf, archery, hang gliding, model aircraft areas, dog parks, boating, water skiing, fishing, camping, velodrome races, and natural and cultural interpretation. A brief discussion of County parks that may contribute to the Plan conservation strategy is included below and summarized in **Table 2-2** (also see **Figure 2-3** for map of open space in the study area, including County parks).

### Almaden Quicksilver County Park

Almaden Quicksilver County Park is located on the western border of the study area, surrounding much of Guadalupe and Almaden Reservoirs. The park was historically used for mining activities and was once home to more than 1,800 miners and their families. The park encompasses 4,152 acres, occupying a majority of Capitancillos Ridge. The park is known for its early spring wildflowers and history surrounding the late 19<sup>th</sup> century mining era.

The park provides over 34 miles of hiking trails, including 23 miles of equestrian trails and 10 miles of bike trails. All trails in the park are open to hikers with pets to walk their dogs on leash (County of Santa Clara, Parks and Recreation Department 2006b).

### Anderson Lake County Park

Anderson Lake County Park is located in the foothills of the Diablo Range east of Morgan Hill and almost entirely (except in the northeast) surrounds Anderson Reservoir, the largest reservoir in Santa Clara County. The 3,144-acre park incorporates other parks including segments of the Coyote Creek Parkway

multiple use trails, the historic Jackson Ranch, the Moses L. Rosendin area, and the Burnett area (County of Santa Clara, Parks and Recreation Department 2006b).

### **Calero County Park**

Calero County Park is located in the eastern foothills of the Santa Cruz Mountains, south San José. The approximately 4,455-acre park offers picnicking, boating and fishing on Calero Reservoir and 18.6 miles of trails in the adjoining oak woodlands. The park contains a trails staging area at the Park office near McKean Road. Additional access is available from the Santa Clara County Open Space Authority (Open Space Authority) Rancho Canada del Oro staging area on Casa Loma Road. Certain uses, such as equestrian group camping, horse and cart activities and special events are by permit only (County of Santa Clara, Parks and Recreation Department 2012). Portions of this park historically have been grazed (J. Mark pers. comm.)

County Parks is developing a Trails Master Plan for Calero County Park to incorporate the 966-acre Rancho San Vicente property acquired in November 2009 into the park (this parcel is also expected to be enrolled in the Habitat Plan Reserve System; see Chapter 5 for interim conservation actions). The Trails Master Plan will also consider expanding the types of trail uses allowed in the park in accordance with provisions of the *Santa Clara County Parks and Recreation System: Strategic Plan* which states that the purpose of a park-specific Trails Master Plan is “to identify opportunities to increase multiple-use trails and to ensure consistency with the Countywide Trails Master Plan and Strategic Plan” (County of Santa Clara, Parks and Recreation Department 2003).

Portions of this park have been grazed in the past (D. Rocha pers. comm.). A Grazing Management Plan was completed for the Canada del Oro property of Calero County Park in 2004 (County of Santa Clara, Parks and Recreation Department 2011; Rana Creek Habitat Restoration 2004). Infrastructure to support implementation of the Grazing Plan is under development. The Rancho San Vicente property of Calero is currently grazed under a managed grazing program through a grazing license with a private operator (D. Rocha pers. comm.).

### **Coyote Creek Parkway**

Coyote Creek Parkway is a 1,694-acre park that meanders along Coyote Creek for 15 miles, bridging the gap between rural and urban parks along the valley floor within the study area. Coyote Creek Parkway ends at Hellyer County Park to the north and Anderson Lake County Park to the south. The Coyote Creek Trail features a 15-mile, 10-foot wide multi-use paved trail between Hellyer County Park and Anderson Lake County Park. The trail is identified in the Countywide Trails Master Plan as a regional trail (Bay Area Ridge Trail and Juan Bautista de Anza National Historic Trail) and as a subregional trail. The north portion features a paved multi-use trail popular with bicyclists, rollerbladers, and hikers. South of Metcalf Road, an equestrian trail parallels the paved trail (County of Santa Clara, Parks and Recreation Department 2006b).

County Parks is implementing the Coyote Creek Park Integrated Plan which is a combined Natural Resources Management Plan and Master Plan adopted by the County Board of Supervisors in 2007. Please refer to the Covered Activities section of this chapter for more details on the resource management plan and master plan.

### **Coyote Lake-Harvey Bear Ranch County Park**

Coyote Lake-Harvey Bear Ranch County Park is located in the western foothills of the Diablo Range, east of San Martin. This 4,595-acre park encompasses Coyote Lake (Coyote Reservoir), providing opportunities for power boating, jetskiing, waterskiing, sailing, canoeing/kayaking and fishing. The lake contains bluegill, black crappie, channel catfish, carp, and black bass. In spring the lake is stocked with rainbow trout. The Bear and Mendoza Ranch sections of the park provide over 18 miles of hiking, biking and equestrian trails. The park is currently grazed under a managed grazing program (J. Mark pers. comm.). A master plan and natural resource management plan were adopted for this park in 2003 (County of Santa Clara, Parks and Recreation Department 2003; Rana Creek Habitat Restoration 2004).

### **Ed R. Levin County Park**

Ed R. Levin County Park is located in the northern most tip of the study area. This 1,541-acre park combines the traditional features of an urban park with the trail system of a regional park. One of the highest points in the study area, Monument Peak, is located in the park. Hikers, equestrians, and cyclists enjoy sections of the park's 19-mile trail system. The southern portion of the park, known as the Spring Valley Area, is named for the many springs that flow freely in this area (County of Santa Clara, Parks and Recreation Department 2006b). In portions of the park, Ed R. Levin County Park supports cattle grazing which is monitored under a natural resource management plan and managed under grazing program (D. Rocha pers. comm.).

### **Joseph D. Grant County Park**

The 9,560-acre Joseph D. Grant County Park is the largest of Santa Clara County's regional parks. It is located on the eastern border of the study area in the Diablo Range. Cattle grazing is allowed in some parts of the park, managed under a grazing program (D. Rocha pers. comm.) and monitored under a natural resource management plan. Hikers and equestrians have access to an extensive 52 mile trail system. Mountain bikes are permitted on nearly half of the park's trails. The diverse trail system at the park makes this a popular place to stage large-scale organized trail events such as equestrian endurance rides, mountain bike events and foot races (County of Santa Clara, Parks and Recreation Department 2006b).

### **Martial Cottle Park**

In 2004, 151 acres of mostly agricultural lands were donated to the County of Santa Clara and 136 acres were sold to State Parks by the owners for preservation as a historic agricultural park. The property is located in the city limits of San José but outside of San José's planning limit of urban growth. This park is entirely surrounded by suburban development but retains some habitat value in its undeveloped state, particularly for western burrowing owls (J. Barclay pers.

comm.). While jointly owned by the County and State Parks, County Parks is responsible for the planning, development and long-term management of the park. In 2011 State Parks and County Parks completed a collaborative master planning process to define guidelines and policies for the site's development, management, operations of recreational, educational and agricultural use opportunities. Due to deed restrictions those long term operations will include intensive agricultural practices which will make it less habitable for native species.

### **Motorcycle County Park**

Motorcycle County Park is the County's only off-road vehicle park. This 442-acre park is located in the foothills of the Diablo Range, east of the southern tip of San José, outside of San José's planning limit of urban growth. The park supports 20 miles of dirt trails (County of Santa Clara, Parks and Recreation Department 2006b).

### **Mount Madonna County Park**

This 3,677-acre park is dominated by redwood forests characteristic of the Santa Cruz Mountains. To the east, the park overlooks the Valley; to the west, Monterey Bay. As the slopes of Mount Madonna descend toward the valley, the landscape changes from redwood forest to oak woodland, dense chaparral and grassy meadows. Hikers and equestrians have access to an extensive 20-mile trail system.

### **Santa Teresa County Park**

Santa Teresa County Park is located in the Santa Teresa Hills ten miles south of downtown San José. This diverse 1,646-acre park offers a variety of recreational opportunities including golf, archery range, an equestrian staging area, and picnic sites for large groups. Additionally, the park offers over 18 miles of unpaved trails for equestrian, hiking and bicycle use, as well as historic resources and interpretive sites. County Parks completed a Grazing Management Plan for the park in 2011; grazing will take place once infrastructure upgrades are completed (D. Rocha pers. comm.). The Coyote Alamos Canal, a facility owned and operated by SCVWD, crosses through the park (County of Santa Clara, Parks and Recreation Department 2006b).

### **Uvas Canyon County Park**

Uvas Canyon County Park is located in the Santa Cruz Mountains, west of Morgan Hill and San Martin, adjacent to Uvas Reservoir. This wooded 1,133-acre park offers hiking, camping, and picnicking opportunities throughout most of the year. The park has seven miles of hiking trails.

### **Uvas Reservoir County Park**

Uvas Reservoir County Park is located in the Santa Cruz Mountains, west of Morgan Hill and San Martin. This park is 626-acre, including the 286-acre reservoir, and is open year round for non-gas powered boating and fishing. No designated trails are available at this park (County of Santa Clara, Parks and Recreation Department 2008).

## **Santa Clara County Open Space Authority**

The Open Space Authority was created on February 1, 1993 by the California State Legislature, in response to efforts by citizens and local governments of Santa Clara County to protect the open spaces that were being threatened by development. The Authority is governed by an elected seven-member board of directors, each representing a unique district. The Authority comprises the cities of Campbell, Milpitas, Morgan Hill, Santa Clara, and San José, as well as much of the unincorporated areas of Santa Clara County. The Open Space Authority's current annual funding is \$4.1 million. The Open Space Authority administers an Urban Open Space Program, which allocates annual funding to the cities within its jurisdiction for open space, habitat and recreational purposes.

The Open Space Authority's Board has defined its purpose as follows.

Preservation of Open Space and creation of greenbelts between communities, lands on the valley floor, hillsides, viewsheds and watersheds, baylands and riparian corridors, are immediate high priorities. These are needed to counter the continuing and serious conversion of these lands to urban uses, to preserve the quality of life in the County and to encourage outdoor recreation and continuing agricultural activities.

Development and implementation of land management policies that provide proper care of open space lands and allow public access appropriate to the nature of the land for recreation are consistent with ecological values and compatible with agricultural uses (Santa Clara County Open Space Authority 2005).

The Open Space Authority operates in approximately the same area as that Plan study area. As of June 2009, the Open Space Authority has preserved 14,494 acres within the study area. Acquisitions have included Rancho Cañada del Oro Open Space Preserve, Sierra Vista Open Space Preserve, and Palassou Ridge Open Space Preserve, which are located in the study area and may contribute to the Plan's conservation strategy (see following discussion below). The Open Space Authority has protected other lands in the Coyote Valley and eastern Diablo Range foothills, as well as agricultural lands located in the southern portion of the county. The Open Space Authority's properties are protected through a combination of conservation easements, fee title purchase, and management agreements (Santa Clara County Open Space Authority 2005). Field staff oversee a wide variety of environmental stewardship, restoration, and monitoring projects. Docents and volunteers provide additional stewardship, interpretation, and outdoor education services.

### **Rancho Cañada del Oro Open Space Preserve**

The 3,602-acre Rancho Cañada del Oro Open Space Preserve is located adjacent to Calero County Park, southwest of San José. Opened in 2004, the facility includes a parking area, restrooms, picnic tables, and an equestrian staging area.

The preserve currently supports more than 13 miles of trails. (Santa Clara County Open Space Authority 2010).

### **Palassou Ridge Open Space Preserve**

The 3,515-acre Palassou Ridge Open Space Preserve (formerly Lakeview Meadows) is located at the eastern edge of Coyote Reservoir, west of Henry W. Coe State Park. This area provides opportunities for preserving uninterrupted habitat corridors and significant riparian and watershed resources between Henry W. Coe State Park and Coyote Lake Harvey Bear Ranch County Park. Trail connections to Henry W. Coe State Park and potentially to the Nature Conservancy lands could provide public access and a component of a future regional trail network.

### **Sierra Vista Open Space Preserve**

The 1,676-acre Sierra Vista Open Space Preserve is located adjacent to Alum Rock Park in the eastern foothills above San José. The preserve encompasses oak woodlands, chaparral, and rolling grasslands, and provides habitat for numerous rare plant and wildlife species. The preserve currently includes more than 10 miles of trails including a portion of the Bay Area Ridge Trail. The Open Space Authority has received grant funding for planning, design, and construction of additional trails and a visitor parking and staging area.

## **City Parks**

Each of the three cities covered by the Plan supports a network of parks and open space. The majority of these parks are managed for intensive recreational use and include such features as athletic facilities, community centers, turf fields, picnic areas, and trails.

Few of the city parks provide important plant or wildlife habitat. One exception is Alum Rock Park in San José. This 740-acre park provides habitat for a variety of wildlife including mountain lions, bobcats, deer, and many small animals. Other city parks that may have important habitat value include Penitencia Creek Park in San José, and Eagle Ridge open space, Uvas Creek Park Preserve, and Christmas Hill Park in Gilroy.

## **Development Mitigation Sites**

All three cities and the county frequently require development projects with significant habitat or scenic resources to set aside a portion of their parcel and dedicate it as permanent open space. In other cases, development projects without enough resources on site are required to conserve land off site. These dedications are often conservation, open space, or scenic easements that are recorded with the property title. Older easements were often dedicated without

any provision for habitat maintenance or monitoring. However, newer easements often contain these provisions and provide endowments or other funding mechanisms to ensure long-term maintenance and monitoring. Sometimes the mitigation sites are transferred to or managed by local land agencies such as the Open Space Authority.

## The Nature Conservancy

Since its founding in 1958, The Nature Conservancy has developed in-depth, science-driven conservation plans for areas throughout the US and the world and has worked on more than 100 projects and preserves in California. Currently, The Nature Conservancy is working to preserve land in central California's Diablo Range between the Silicon and Central Valleys, including Mount Hamilton and its surrounding foothills. The Conservancy's Mount Hamilton Project seeks to protect the most ecologically critical 500,000 acres of this landscape by working with local cattle ranchers, public agencies, and other partners. The Mount Hamilton Project, launched in 1998 with the acquisition of the 32,800-acre Simon Newman Ranch in Stanislaus and Merced Counties, and the 28,100-acre Romero Ranch in Stanislaus and Santa Clara Counties, seeks to protect 250,000 acres of wilderness land through outright acquisitions and conservation easements (The Nature Conservancy 2006). In early 2008, this effort was bolstered by the establishment of a conservation easement on the 28,359-acre San Felipe Ranch. To date, The Nature Conservancy has permanently protected roughly 110,000 acres in the Mount Hamilton Range, approximately 51,350 acres of which are in the study area (**Table 2-2**).

The Nature Conservancy's strategy is to protect ecologically sensitive or unique sites and to connect the extensive public lands in the area—state, County and regional parks; university lands; and water district holdings—by securing the permanent protection of key private properties that surround and link them through conservation easement or purchase in fee title. The Nature Conservancy has been involved as a stakeholder in NCCP planning processes since the creation of the NCCP Act and has a long history of successful acquisition and stewardship efforts in NCCP reserve areas throughout the state.

Within the study area, The Nature Conservancy has acquired both permanent conservation easements and fee title to ranches east of U.S. 101. Land acquired in fee title has been transferred to land management agencies such as Henry W. Coe State Park, the CDFG, and the Open Space Authority (The Nature Conservancy 2006).

### 2.2.5 Protection and Resource Management Status of Open Space Lands

Public and private open space lands within the study area are subject to a variety of resource-management regimes. As a result, existing open space provides

different habitat quality for the covered species and natural communities. Because some of these existing open space lands may be relied upon to support the Reserve System, existing open space areas need to be distinguished by their values for the Plan conservation strategy. To do this, open space lands have been categorized as described below.

The value of protected open space areas for covered species and natural communities is greatest when land use protections are in place in perpetuity. The value of open space for the Plan is similarly improved when a natural resource management plan is in place and adequate funding exists to maintain or enhance populations or natural communities. Open space areas that do not have land use protections in perpetuity but do have ecological protection as their primary management goal may still support the Reserve System. However, unless permanent conservation easements are acquired for these areas, they will not be part of the Reserve System because of the risk of changes in land use or resource management emphasis.

The following classification of open space was developed to account for differences in land use protections and resource management emphasis and to assist in the development of the Plan conservation strategy.

## Open Space Classification

Protection and resource management status of open space lands has been evaluated and classified based on the level of land use protection and the general level of ecological management. Each open space unit within the study area was assigned one of four resource management types as shown in **Table 2-3**. The decision-making process used to assign open space lands to these types is shown in **Figure 2-4**.

Lands assigned to Type 1 and Type 2 open space categories have natural resource management and ecological protection as their primary purpose. Type 1 open space lands are protected from land use change by irrevocable means such as a conservation easement in perpetuity; or a local, state, or federal law. Local examples of Type 1 open space include lands owned by The Nature Conservancy, lands that are under a permanent conservation easement, and habitat or species mitigation lands subject to permanent easement. It is understood that the extent of ecological protection and management that actually occurs on these lands is subject to the availability of funding. The designation of Type 1 or Type 2 open space notes that the land use protections are in place on those lands, provided the funding becomes available.

If land use protections are not in perpetuity, but the purpose of land management is still ecological protection, then the land is assigned to Type 2 open space. If ecological protection is not the primary goal, but the land is managed as open space with some ecological value<sup>5</sup>, then it is assigned to Type 3 open space. If

<sup>5</sup> Allows multiple species to complete some portion of their life cycle (e.g., reproduction, growth, foraging) or provides critical refuge and movement opportunities (e.g., migration corridor).

the land is managed as open space, but offers little or no long-term or measurable ecological value, then it is assigned to Type 4 open space.

There are various types of open space in the unincorporated county in the study area including: 45,786 acres of Type 1 open space; 76,606 acres of Type 2; 37,065 acres of Type 3; and 4,109 acres of Type 4. Ninety one percent (91%) of all open space in the unincorporated county within the study area is owned by five entities: the California Department of Fish and Game owns 2%, the Open Space Authority owns 7%, The Nature Conservancy owns 23%, County Parks owns 24%, and State Parks owns 35%.

## 2.3 Covered Activities

This section describes the activities and projects within the permit area that will be covered by the final permits and for which the Plan will provide avoidance, minimization, and compensation (i.e., conservation) for impacts to covered species and natural communities. “Activities” are actions that occur repeatedly in one location or throughout the permit area. “Projects” are well-defined actions that occur once in a discrete location. Together, these activities and projects are the *covered activities* for which incidental take authorization from the Wildlife Agencies will be obtained. All activities described in Section 2.3 *Covered Activities* are covered activities that have been analyzed in Chapter 4 *Impact Assessment and Level of Take* unless specifically identified as not covered. Covered activities described in Sections 2.3.1 through 2.3.7 are covered activities that will be implemented by the Local Partners and private developers subject to the jurisdiction of the Local Partners. Covered activities described in Section 2.3.8 *Conservation Strategy Implementation* are associated with implementation of the Plan’s conservation strategy or recreation in the Reserve System and will be the responsibility of the Implementing Entity or, in the case of recreation, the owner of the land in the Reserve System (e.g., Implementing Entity, County Parks, Open Space Authority).

All parties seeking coverage for activities and projects under the Plan must obtain approval from the Permittee with jurisdiction over the activity or project or the location where the activity or project is proposed for implementation (city, County, or special district; see Chapter 6 *Conditions on Covered Activities and Application Process* for a description of the approval process).

All covered activities must incorporate the relevant conditions on covered activities described in Chapter 6 in order to avoid or minimize impacts to covered species and natural communities. Part of the approval process for parties seeking coverage under the Plan is demonstration that the conditions have been incorporated or will be incorporated properly into proposed projects. The descriptions of covered activities in this chapter have been written to be as consistent as possible with the conditions in Chapter 6. If any inconsistencies remain, the condition takes precedence over the description in this chapter. For complete details on the conditions on covered activities, see Chapter 6.

Projects and activities may only be covered if a Local Partner has control over design, avoidance and minimization, and mitigation associated with the project (as described in Chapter 5 *Conservation Strategy* and Chapter 6 *Conditions on Covered Activities and Application Process*). Local Partners may partner with other federal or state agencies, (e.g., the Corps or the California Department of Transportation) to develop the project, but the Local Partner must have control over the above described aspects of the project in order to ensure the terms of this Plan are implemented.

Development projects, or portion thereof, that are in the process of receiving local jurisdiction approvals at the time the Habitat Plan is adopted (i.e., “pipeline projects”) will not be subject to the Habitat Plan if all of the following apply:

1. it has received at least one of the following approved development entitlements with a specified expiration date (including allowed renewals/extensions) prior to Habitat Plan adoption: site and architectural permit/approval, planned development approval, conditional use approval, or a tentative map; and
2. it is issued a grading or building permit within 1 year of issuance of the Habitat Plan’s state and federal incidental take permits; and
3. the project review process identified no impacts to any of the Habitat Plan’s covered species.

This provision applies only to the portion of a project that is issued grading and/or building permit(s) within the 1-year period.

Activities or projects that do not fall clearly within the descriptions provided in this chapter will be evaluated on a case-by-case basis. If the Implementing Entity determines that a specific type of project or activity is not included within the descriptions in this chapter, then it will not receive coverage under this Plan. Any uncertainties regarding whether a type of project or activity can receive coverage under this Plan will be resolved by the Implementing Entity.

A described activity or project will be covered under the Plan if:

- the activity or project does not preclude achieving the biological goals and objectives of the Plan (see Chapter 5 *Conservation Strategy*) as determined by the Implementing Entity at the time the covered activity is proposed. For projects where there is some question whether or not the biological goals and objectives of the Plan may be precluded, the determination will be made by the Implementing Entity in coordination with the Wildlife Agencies;
- the activity or project is conducted by, or is subject to the jurisdiction of, one of the Permittees (see Chapter 8 *Plan Implementation* for a mechanism for a non-permittee to receive coverage under the Plan);
- the activity or project is a type of impact evaluated in Chapter 4 of the Plan; and

- adequate take coverage<sup>6</sup> under the permits remains available for other covered activities.

This definition includes projects that are currently anticipated and identified in this chapter, but that do not yet have fully developed project descriptions or plans. Provided that these projects meet the criteria above, they may be covered by this Plan. Project-specific identification as a covered activity, either in this chapter or through a future determination by the Implementing Entity, does not imply or grant entitlement for implementation. Project applicants are required to gain other project approvals from local jurisdictions and other regulatory agencies as necessary.

All covered activities described in this chapter apply to the two permits (CDFG and USFWS), with one exception. The use of pesticides, including herbicides and rodenticides, is not covered by the federal permit because USFWS has not authorized the EPA to certify their use.

## 2.3.1 Methods for Identifying Covered Activities

To begin the process of determining covered activities, the Permittees developed comprehensive lists of activities and projects under their direct control or jurisdiction that might have a need for take coverage. The following five criteria were used to screen the lists. Candidate activities and projects needed to meet all five criteria to be considered covered activities under the Plan.

1. **Location:** The project, activity, or government service will occur within the Plan permit area.
2. **Timing:** Construction of the project or implementation of activities is scheduled to begin after the Plan is approved and the project is completed within the term of the permit.
3. **Impact:** The project or activity has a reasonable potential or likelihood to take a covered species. Highly unlikely or speculative take will not meet this criterion.
4. **Definition:** The location, size, and other relevant aspects of the project or activity can be defined well enough such that direct and indirect impacts to covered species can be evaluated and conservation measures developed to mitigate those impacts.
5. **Practicability:** Inclusion of the project, activity, or government service as a covered activity will not result in undue delays or substantial additional cost to Plan development and permitting process relative to the benefit of including the project/activity in the permit. In other words, it will not be more cost effective to permit the project/activity separately. Examples of impractical covered activities are ones that, on their own, would add

---

<sup>6</sup> Take coverage is defined in this Plan in terms of land cover type, modeled habitat (see **Tables 4-2 and 4-4**), and occurrences of covered plants (see **Table 4-6**) adversely affected as a result of covered activities.

additional covered species, generate substantial controversy, or significantly complicate the impact analysis.

## Covered Activity Categories

For the purposes of this Plan, covered activities fall into seven general categories.

- Urban Development.
- In-stream Capital Projects.
- In-stream Operations and Maintenance.
- Rural Capital Projects.
- Rural Operation and Maintenance.
- Rural Development.
- Conservation Strategy Implementation (activities within the lands managed, enhanced, restored, and monitored to conserve the natural resources targeted by this Plan).

Covered activities are identified below for each of these seven categories. The activities described are those activities for which incidental take authorization will be requested by the Permittees.

The activities identified below broadly define all of the different types of activities covered by this Plan. In some cases, specific projects are identified as examples to illustrate the general category. However, if a given project meets the guidelines for covered activities as described in the first part of this section, then that project is a covered activity.

It is expected that the Permittees will develop additional activities and projects over the course of the permit term of this Plan. To the extent that these additional activities and projects are generally and qualitatively described below, meet the criteria in Section 2.3 *Covered Activities* above, are not expressly limited by this chapter, and are adequately evaluated in Chapter 4 of this Plan, these future activities and projects will also be covered by this Plan.

Descriptions of covered activities in this chapter are mostly qualitative. Additional quantitative assumptions of covered activity footprints and frequency of occurrence are described in the impact analysis methodology in Chapter 4.

### 2.3.2 Urban Development

This category includes projects and activities that occur inside the planning limits of urban growth (see **Figure 2-2**) but outside of in-stream areas (streams and adjacent riparian vegetation) and excluding those areas identified in Section 2.2.3 *Planning Limits of Urban Growth* as these will be developed consistent with

rural development land use patterns. In-stream covered activities are discussed in Sections 2.3.3 *In-Stream Capital Projects* and 2.3.4 *In-Stream Operations and Maintenance*. This category is intended to be as inclusive as possible to accommodate urban growth and all ground-disturbing activities within designated urban areas. It includes the construction and maintenance of typical urban facilities, public and private, consistent with local general plans and local, state, and federal laws. This category of covered activities includes, but is not limited to, the construction, maintenance, and use of the following urban facilities.

- Residential, commercial, industrial, and other types of urban development within the cities of Gilroy, Morgan Hill, and San José planning limits of urban growth in areas designated for urban or rural development, including areas that are currently in the unincorporated County (i.e., in “pockets” of unincorporated land inside the cities’ planning limits of urban growth).
- Residential, commercial, industrial, and other types of urban development within the San José–designated North Coyote Campus Industrial Area in areas with land use designated for urban development, rural development, and agricultural development as identified in **Figure 2-2**.
- Transportation facilities including sidewalks, bike paths, paved and unpaved roads, bridges, culverts, and transit facilities.
- Public service and cultural facilities including new fire stations, police stations, community policing centers, communications facilities, public administration centers, convention centers, theatres, museums, community centers, community gardens, and concession buildings.
- Recreational facilities such as neighborhood parks, dog parks, soccer fields, golf courses, indoor and outdoor sports centers, racetracks, campgrounds, and trails, and associated infrastructure including roads, bridges, parking areas, and restrooms.
- Public and private utilities including electric transmission and distribution lines, telecommunications lines, and gas pipelines. Solar energy projects are covered by the Plan as long as their impacts to covered species and natural communities are consistent with the evaluation of effects in Chapter 4.
- City water delivery and storage facilities including water treatment plants, water supply pipelines, percolation ponds, and pump stations (SCVWD is the water wholesaler in the county and serves local water suppliers).
- Stormwater management facilities such as storm sewer systems, nonpoint source reduction, outfalls, and drainage improvements.
- Waste-management facilities including sewage-treatment plants, sanitary sewer systems and rehabilitation, water recycling, recycling centers, transfer stations.
- Funeral/interment services including mortuaries, crematorium, columbaria, mausoleums, and similar services when in conjunction with cemeteries.
- Vegetation management including fuel reduction (including hand and mechanized removal and controlled burns), tree removal and pruning,

grazing activities, exotic vegetation control/removal, hazardous tree work, weed abatement, algae control in ponds.

- Hazardous material remediation for, and restoration related to, abandoned dumps (e.g., Singleton Landfill).

The Cities of San José, Gilroy, and Morgan Hill have developed several planning documents that outline strategies and projects consistent with current general plans. Examples of current plans that apply to planning in urban areas within the study area include the following.

- City of San José Greenprint (City of San José 2000).
- City of San José Alum Rock Park Riparian Management Plan (Biotic Resources Group 2001).
- City of San José Sanitary Sewer Master Plan (City of San José 2004).
- City of San José Storm Sewer System Capital Program (City of San José 2006b).
- City of San José Sanitary Sewer System Capital Program (City of San José 2006c).
- City of San José and City of Santa Clara Draft San Jose/Santa Clara Water Pollution Control Plant Master Plan (City of San José and City of Santa Clara 2011)<sup>7</sup>.
- City of Morgan Hill Redevelopment Agency Implementation Plan (City of Morgan Hill 2004).
- City of Morgan Hill Downtown Specific Plan (City of Morgan Hill 2009).
- City of Morgan Hill Parks, Facilities & Recreation Programming Master Plan (City of Morgan Hill 2001c).
- City of Morgan Hill Bikeways Master Plan Update (City of Morgan Hill 2008).
- City of Morgan Hill Trails and Natural Resources Study (City of Morgan Hill 2007).
- City of Morgan Hill Capital Improvement Program (City of Morgan Hill 2002a).
- City of Morgan Hill Sewer System Master Plan (City of Morgan Hill 2002b).
- City of Morgan Hill Storm Drainage System Master Plan (City of Morgan Hill 2002c).
- City of Morgan Hill Water Master Plan (City of Morgan Hill 2002d).
- City of Morgan Hill Environmental Programs (City of Morgan Hill 2007).
- City of Gilroy Bicycle Master Plan (City of Gilroy 2002c).

<sup>7</sup> Only those portions of the San José/Santa Clara Water Pollution Control Plant Master Plan area that are inside the study area (which does not include the extended study area for burrowing owl conservation) may be covered by the Habitat Plan.

- City of Gilroy Parks and Recreation Systems Master Plan (City of Gilroy 2002d).
- City of Gilroy Sanitary Sewer Master Plan (City of Gilroy 2004a).
- City of Gilroy Storm Drain Master Plan (City of Gilroy 2004b).
- City of Gilroy Traffic Master Plan (City of Gilroy 2004c).
- City of Gilroy Water Master Plan (City of Gilroy 2004d).
- City of Gilroy Glen-Loma Specific Plan (City of Gilroy 2005a).
- City of Gilroy Trails Master Plan (City of Gilroy 2005c).
- City of Gilroy Wastewater Treatment Plant Master Plan (City of Gilroy 2006b).
- South County Recycled Water Master Plan (Santa Clara Valley Water District and South County Regional Wastewater Authority 2004).

Additional plans will be developed over the course of the permit term of this Habitat Plan. Activities proposed in these future plans that are consistent with the criteria in Section 2.3 *Covered Activities* and that have been adequately addressed in the impacts analysis contained in Chapter 4 and the conservation strategy described in Chapter 5 will also be covered by this Plan.

## Private Development Subject to the Plan

Private development activities that require ground disturbance are subject to the Habitat Plan if the activity meets the following criteria.

1. The activity is subject to either ministerial or discretionary approval by the County or one of the cities;
2. The activity is described in Section 2.3.2 *Urban Development* or in Section 2.3.7 *Rural Development*; and
3. In **Figure 2-5**<sup>8</sup>, the activity is located in an area identified as “Private Development is Covered,” OR

The activity is equal to or greater than 2 acres AND the project is located in an area identified as “Rural Development Equal to or Greater than 2 Acres is

<sup>8</sup> **Figure 2-5** *Private Development Areas Subject to the Plan* was developed to distinguish areas where, with respect to future rural development, there is higher biodiversity and a greater chance for “take” of covered species versus areas where habitat values are lower and the potential for “take” is relatively low. Information sources used in defining these areas included USFWS critical habitat; areas mapped by the Plan (**Figure 3-10**) as serpentine, wetland, stream, riparian, or pond land cover types; conservation analysis zones with a “high” conservation effort designation (**Figure 5-7**); and mapped occurrences of covered wildlife species. In areas where this information indicated a higher potential for presence of covered species, rural development projects are subject to the Habitat Plan. In areas where the information indicates a low probability that covered species are present, rural development projects are not subject to the Habitat Plan. **Figure 2-5** will be updated throughout the permit term to reflect new information collected during Plan implementation.

Covered,” or “Urban Development Equal to or Greater than 2 Acres is Covered” OR

The activity is located in an area identified as “Rural Development is not Covered” but, based on land cover verification of the parcel (inside the Urban Service Area) or development area (for rural development projects; see Section 6.8 *Habitat Plan Application Package*), the project is found to impact serpentine, wetland<sup>9</sup>, stream, riparian, or pond land cover types; or the project is located in occupied or occupied nesting habitat for western burrowing owl (see **Figure 5-11** and **Appendix D Species Accounts**).

In addition, private development additions of less than 5,000 square feet of new impervious surface to existing developed sites, regardless of parcel size, are not subject to the Plan.

Projects that are not subject to the Habitat Plan because they do not meet these criteria are *not exempt from compliance with the ESA or CESA*. If a project has the potential to take a federally or state listed species, the applicant must contact USFWS and/or CDFG to determine whether a take authorization should be obtained. Project applicants may request to “opt in” to the Habitat Plan and receive take coverage by complying with all of the conditions and application processes described in this Plan (see Chapter 6). Opt in coverage is not guaranteed and will be authorized by the local jurisdiction in consultation with the Implementing Entity.

This coverage determination process only applies to private urban and rural development that requires a permit from a city or the County. It does not apply to activities initiated by the Local Partners or Participating Special Entities (see Section 8.4 *Participating Special Entities* for more information).

### 2.3.3 In-Stream Capital Projects

The term *in-stream* is defined for the purposes of this Plan as the stream bed and bank, and the surrounding adjacent riparian corridor. This category addresses public infrastructure projects that occur within streams. Activities within streams are those activities or projects that occur in or immediately adjacent to creeks and that may result in impacts to a creek or canal. This category includes activities in the stream channel, along the stream bank, and adjacent lands at top-of-bank within the riparian corridor. These covered activities occur in both urban and rural areas. Known locations of in-stream capital projects are shown in **Figure 2-6**. The operation and maintenance of these projects, as well as existing facilities, are described in Section 2.3.4 *In-Stream Operations and Maintenance*.

In-stream capital projects and activities that are covered under this Plan include the following activities.

<sup>9</sup> If during the environmental review process it is shown that a project has adverse indirect impacts to a wetland’s function (change in hydrological functions, etc.), the project will be subject to the Plan.

- Activities described above under Section 2.3.2 *Urban Development* that overlap with streams. Activities include transportation, water supply, wastewater management, and stormwater management.
- Construction or reconstruction of flood protection projects and maintenance of associated access roads (see discussion in following section).
- Reconstruction of levees.
- Three Creeks Habitat Conservation Plan geomorphic rehabilitation and gravel program.
- Reconstruction, realignment, and decommissioning of SCVWD canals.
- Dam-related capital projects.
- In-channel groundwater recharge facilities.
- Bridge construction, replacement, and major repair including vehicular, train, and pedestrian bridges (see discussion in following section below).
- Bridge construction in County parks including vehicular bridges, multi-use bridges, footbridges, puncheons, and rock bridges (i.e., rocks placed across a small stream along a single-track trail).
- Culvert installation and maintenance.
- Creekside trail projects and associated bridges (trails are discussed in more detail in Section 2.3.5 *Rural Capital Projects*).
- Implementation of SCVWD's Dam Instrumentation Project. Activities include a field geotechnical exploratory drilling program and providing a corresponding Automated Data Acquisition System for the eight SCVWD dams within the study area (see discussion below).
- Fish passage barrier removals.

Capital projects that are covered under this Plan are discussed in more detail in the following sections.

## Flood Protection Projects

SCVWD maintains a rolling 5-year Capital Improvement Program that determines which projects are developed over time. SCVWD has several capital projects planned to address flood protection. These projects have been identified through various programs that provide different funding mechanisms and guiding principles of how projects will be planned and designed. Two such programs are the Clean, Safe Creeks and Natural Flood Protection Plan and the Coyote Watershed Stream Stewardship Plan. Each plan is briefly described below. Flood protection projects identified in these plans are described at the end of this section.

The Clean, Safe Creeks and Natural Flood Protection Plan is a single, countywide special tax-funded 15-year plan, part of the SCVWD flood

protection and stream stewardship program. Performing public oversight for this program is an independent monitoring committee, which annually reviews the implementation of the Program. As part of the Clean, Safe Creeks and Natural Flood Protection Program, SCVWD is directed to protect public health and safety and enhance the quality of life within Santa Clara County. Initiated in 2000, it identifies four outcomes: provide flood protection, protect water quality, enhance and restore in-stream and riparian ecosystems, and provide recreational access. The first outcome, flood protection, includes the flood control capital control projects. During project planning, flood protection projects are prioritized by flooding history, damage estimates, and economic impacts. Project design protects against a 1% flood while improving water quality, restoring natural habitat, and providing recreational and operations and maintenance access (Santa Clara Valley Water District 2000). Of the covered flood protection capital projects described below, improvements to Berryessa Creek, Coyote Creek, and Upper Penitencia Creek are partially funded by the Clean, Safe Creeks and Natural Flood Protection Plan.

The Coyote Watershed Stream Stewardship Plan addresses flooding and environmental issues through an integrated approach to watershed management. SCVWD developed the Coyote Watershed Stream Stewardship Plan to provide a strategic approach for implementing the Ends Policy using a watershed management approach to provide stream stewardship within the Coyote watershed. The Ends Policy, in part, envisions a watershed in which (1) there is a healthy and safe environment for residents and visitors, and (2) there is an enhanced quality of life in Santa Clara County (Santa Clara Valley Water District 2002). This plan documents long-range projections of several agencies, incorporates information from ongoing SCVWD projects, and defines future projects and strategies to achieve SCVWD's Ends Policy in the watershed. Projects implemented under this plan include, but are not limited to, flood control projects, new trails, acquisition of open space, and stormwater detention and infiltration (Santa Clara Valley Water District 2002). Examples of projects partially funded through the Coyote Watershed Stream Stewardship Plan include the Berryessa Creek Project and the Lower Silver Creek between Interstate 680 (I-680) and Lake Cunningham. In designing projects through both programs, SCVWD uses methods that balance flood protection with protection of streams and natural resources. Examples of these methods include expanding the in-channel flood plain in areas where the existing channel is highly constrained, and installing bypass channels to reduce the quantity of water flowing through natural streams during high flows, thus reducing flooding and scouring potential. These flood-protection technologies help keep streams as natural as possible.

## **Flood Protection Project Design Elements**

Flood protection capital improvement projects incorporate design elements that provide onsite impact avoidance, minimization, and mitigation for both in-stream and riparian habitat. Enhancement and creation of riparian habitat is coupled with removal of invasive species and planting of native species. In-stream design elements include fish passage improvement through the removal of fish barriers, placement of fish ladders, and other in-stream habitat enhancements. Finally,

design elements protect in-stream water quality by reducing erosion, sedimentation, and turbidity, as well as removing unauthorized storm drain outfalls (Santa Clara Valley Water District 2000).

Flood control design components that may be utilized include those listed below.

- Regrading of bank slopes.
- Realignment of the historic full channel or active low-flow channel.
- Installation of hardscape, including at stream crossings (concrete or riprap).
- Installation of grade control features (e.g., check dams, vortex weirs, cross vanes, drop structures, step pools, and rock riffles) to control erosive velocities.
- Temporary stream diversion during construction.
- Planting<sup>10</sup>.
- Channel widening.
- Levee reconstruction activities including installation or improvement of floodwalls and/or levees. Flood protection levee work may result in a raised or expanded levee. (Reconstruction activities are further described in the following section *Levee Reconstruction*.)
- Permanent bypass or diversion channel construction.
- Acquisition of right-of-way and maintenance road construction.
- Installation of culverts or outfall structures, including inlet and outlet structures for detention basins.
- Off-channel detention basins.

Planning and design of flood protection projects requires several years to decades to complete. Construction may take weeks or years to complete, depending on whether the project is phased over time and the nature of the project in a given reach. The process is often complicated when multiple agencies are participating in the project. As such, it is difficult to identify a timeline within which these projects may be implemented. SCVWD will apply all conditions as described in Chapter 6 when implementing flood protection projects, including review and approval by the Wildlife Agencies as described in Section 8.7.3 *Wildlife Agency Responsibilities*.

Those projects for which project descriptions are currently available are described below. For those projects for which no project description has been developed, a brief description of project location is provided. These projects will contain the same types of design elements as those for which a project description has been developed because of SCVWD's commitment to flood protection and stream stewardship as described above. **Tables 4-5a and 4-5b**

<sup>10</sup> All planting will be implemented to allow proper flood conveyance and will consist of hydroseeding on all earthen surfaces above the channel bed and tree planting at the top of bank, with a few additional trees planted on bank slopes and at toe-of-slope.

describe key assumptions used to estimate impacts associated with these projects that could not be fully described during Plan development.

Coverage for SCVWD flood protection projects is limited to 64 miles of total project length with a maximum of 3.1 miles of permanent stream impacts.

## Coyote Watershed

**Berryessa Creek—I-680 to Old Piedmont Road.** Berryessa Creek is a tributary of Coyote Creek located in San José. The project extends approximately 2 miles between I-680 and just upstream of Old Piedmont Road. Currently the creek has sections that are natural, a section that is a trapezoidal concrete channel, and a concrete lined in-stream sediment basin. Specific design details for this project area have not been developed at this time; however, they will be consistent with the design elements described above.

**Coyote Creek—U.S. 101/I-85 to Metcalf Road.** Coyote Creek is an urban stream within San José. This reach is 5.6 miles and is bordered by the Coyote Creek Park. Between I-85/U.S. 101 interchange and Metcalf Road, the reach is modified to form the Parkway Lakes. The project extends from the I-85/U.S. 101 to Metcalf Road. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**Coyote Creek—I-280 to U.S. 101.** Coyote Creek is an urban stream within San José. This reach is 6.7 miles and is bordered by the Coyote Creek Park. The project extends from I-280 to U.S. 101. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**Fisher Creek—Bailey Avenue to Hale Avenue.** Fisher Creek is a tributary of Coyote Creek. The reach is 5.4 miles and flows from Morgan Hill through unincorporated San José and into Coyote Creek at its intersection with Monterey Highway in San José. The project extends from Bailey Avenue in unincorporated San José to Hale Avenue in Morgan Hill. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above. It is possible that the City of San José will be the lead on this project instead of SCVWD.

**Mid-Coyote Creek—Montague Expressway to I-280.** The project extends approximately 6.1 miles between Montague expressway and I-280, all in the City of San José. Still in the planning phases, the project is expected to include channel capacity improvements such as levee construction, channel excavation, bridge replacement, property acquisition and structural removal. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**Quimby Creek—Thompson Creek to Headwaters.** Quimby Creek is a tributary of Thompson Creek. Within San José it is highly channelized. The

project extends 1.2 miles from Thompson Creek to its headwaters. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**Sierra Creek—Berryessa Creek to Headwaters.** Sierra Creek is a tributary of Berryessa Creek in San José. Within the urban limits it is highly channelized, composed of a concrete trapezoidal channel. The project extends 2.4 miles from the stream's headwaters to Berryessa Creek. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**South Babb Creek—Lower Silver Creek to Headwaters.** South Babb Creek is a tributary of Lower Silver Creek extending from unincorporated San José into San José. It is currently a culvert/trapezoidal concrete channel. Specific design elements for this 0.9 mile project have not been developed at this time; however, they will be consistent with the design elements described above.

**Upper Penitencia Creek—Coyote Creek to Dorel Drive.** This project occurs along approximately 4.2 miles of Upper Penitencia Creek, from the confluence with Coyote Creek to Dorel Drive. Project goals include the following.

- Provide one-percent flood protection to more than 5,000 homes, businesses and public buildings;
- Improve stream habitat values and fisheries potential;
- Reduce sedimentation and maintenance requirements;
- Identify opportunities to integrate recreation improvements consistent with the Master Plan of the City of San José and Santa Clara County Parks;
- Obtain a Letter of Map Revision from the Federal Emergency Management Agency (FEMA); and
- Incorporate SCVWD's Clean, Safe Creeks and Natural Flood Protection Program objectives.

Design elements include a concrete culvert, percolation pond, realignment of the creek at I-680, levees and floodwalls, modified floodplains, and residential home floodproofing.

**Upper Silver Creek—U.S. 101 to Coyote Creek.** Upper Silver Creek is a tributary of Coyote Creek within San José. They converge just south of Coyote Creek's intersection with Capitol Expressway and northwest of U.S. 101. The channel is composed of earthen levees and excavated earth. The project extends 0.7 mile from U.S. 101 to Coyote Creek. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**Upper Silver Creek—U.S. 101 to Silver Creek Road.** Upper Silver Creek is a tributary of Coyote Creek within San José. They converge just south of Coyote Creek's intersection with Capitol Expressway and northwest of U.S. 101. The channel is composed of earthen levees and excavated earth. The 1.2 mile project

extends from U.S. 101 to Silver Creek Road. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

## Guadalupe Watershed

**Alamitos Creek—Guadalupe River to Almaden Dam.** The project extends 7.4 miles from Almaden Dam to the Guadalupe River. Specific flood protection design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above. In addition, design elements will also include fish barrier modifications both at the gabion structure upstream of Mazzone Drive and at the creek's confluence with the Guadalupe River.

**Arroyo Calero—Alamitos Creek to Calero Dam.** Arroyo Calero runs from Calero Reservoir to Alamitos Creek through unincorporated County into San José. The project extends the entire 4 mile extent of the arroyo. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**Canoas Creek—Guadalupe River to Cotle Road.** The project extends 7.4 miles from Canoas Creek's confluence with the Guadalupe River to Cotle Road. Design elements include the construction of 3.5-foot-high floodwalls along Canoas Creek from Almaden Expressway to the end of Nightingale Drive (Santa Clara Valley Water District 1999).

**Los Gatos Creek—Kirk Dam to Lark Avenue.** Los Gatos Creek is a tributary of the Guadalupe River. The project extends 0.7 mile from Kirk Dam to Lark Avenue within the cities of Los Gatos and Campbell, within a right-of-way owned by SCVWD. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**Randol Creek—Alamitos Creek to Bret Harte Drive.** Randol Creek is a highly channelized tributary of Alamitos Creek in San José. It is primarily a trapezoidal earthen channel with periodic concrete structures for flood control purposes. The project extends approximately 0.5 mile from Bret Harte Drive to Alamitos Creek. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**Ross Creek—Guadalupe River to Kirk Avenue.** Ross Creek is a highly channelized tributary of the Guadalupe River. It is primarily a trapezoidal earthen channel with periodic and various hard structures for flood and bank protection purposes. The approximately 1.6-mile project reach extends from Guadalupe River to Kirk Avenue in San José. Currently, Ross Creek is primarily a trapezoidal earthen channel. Design elements include widening the channel bottom to 30 feet with 1:1 side slopes and lining both banks with articulated concrete mat. An 18-foot maintenance road will be established on the south top

of bank and depressed 3 feet below grade for security of adjacent properties. If necessary, the existing streamflow gauge station will be replaced in coordination with technical support staff. In addition, a second 20- by 10-foot RCB culvert will be added on the north side of the existing culvert under Almaden Expressway. A concrete apron will be constructed at the outlet of the culvert. The existing sewer line in Almaden Expressway will be relocated in coordination with the City. Similarly, at Jarvis Avenue, a second 13- by 9.5-foot box culvert will be constructed. Design elements will also include fish passage modifications (Santa Clara Valley Water District 1999). Where applicable, revegetation and other riparian habitat enhancements will be included.

## Uvas Watershed

**Gavilan Creek—Uvas Creek to Headwaters.** Gavilan Creek varies from a trapezoidal earthen channel to a clay-lined channel and contains a variety of flow control structures including culverts, energy dissipaters, drop structures, pipelines, and sacked concrete riprap lining. The 3.1-mile project runs from Uvas Creek to the headwaters Gavilan Creek. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**Uvas-Carnadero Creek—Pajaro River to Watsonville Road.** Uvas-Carnadero Creek, in the vicinity of Gilroy, is the major river in the Uvas watershed. The project will extend 13.8 miles from the Pajaro River to Watsonville Road as the upper boundary. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above. Design elements will also include fish passage and habitat modifications.

## Llagas Watershed

**East Little Llagas Creek—U.S. 101 to Headwaters.** East Little Llagas Creek is in the vicinity of Gilroy. The project will be conducted in a rural setting and extends 0.8 mile from U.S. 101 to the creek's headwaters. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**Jones Creek—Llagas Creek to Alamias Creek.** Jones Creek is in the vicinity of Gilroy. The project will be conducted in a rural setting and extends 2.4 miles from Llagas Creek to Alamias Creek. Specific design elements for this project have not been developed at this time; however, they will be consistent with the design elements described above.

**Lions Creek—Sta 102+00 to Headwaters.** Lions Creek is in the vicinity of Gilroy. The 1.1-mile project will be conducted in a rural setting and extends from U.S. Geological Survey (USGS) gauge station 102+00 to the headwaters of Lions Creek. Specific design elements for this project have not been developed

at this time; however, they will be consistent with the design elements described above.

**West Little Llagas Creek—Wright Avenue to Llagas Road.** The project extends 0.6 mile from Wright Avenue to Llagas Road and includes two reaches: 7 and 8a. Reach 7 is further subdivided into Reach 7a and 7b, as different design elements will be applied to each subsection. Design elements for Reach 7 are uncertain. In the Llagas Creek EIR (U.S. Department of Agriculture 1982), design elements for Reach 7a (1.6 miles) include 1 mile of excavated trapezoidal/earthen channel with depressed maintenance roads and a rock-lined pilot channel, as well as installation of a grade stabilization structure. Design elements for Reach 7b (0.9 mile) include earthen channel excavation with a depressed maintenance road and a pilot channel. Design elements for reach 8a (1.0 mile) include installation of a rectangular concrete channel. In the more recent Llagas Status Report (Santa Clara Valley Water District 2007c), design elements for Reach 7 are not subdivided and are described as construction of an earthen channel diversion and an earthen channel.

## Levee Reconstruction

SCVWD owns or maintains approximately 91 miles of levees or similar flood reduction facilities. Approximately 23 miles of these levees are within the study area. Sections of these levees are currently under the jurisdiction of the Corps, but jurisdiction is not constant and may change over the course of the permit term (e.g., a section of levee currently under Corps jurisdiction may not be under Corps jurisdiction in 20 years). Reconstruction of 10 miles of the approximately 23 miles of levees are covered by this Plan (see Section 2.4 *Projects and Activities not Covered by this Plan* for information on levee reconstruction projects that are led by the Corps). The 10 miles of levee reconstruction assumed for this Plan is additive to levee improvements conducted as part of a flood protection project. As described in Chapter 8, the Wildlife Agencies will have design review and approval authority over flood protection projects and levee reconstruction projects that are covered by the Habitat Plan.

The Corps has revised its inspection standards and compliance (enforcement) requirements for levee systems under their jurisdiction which are maintained by local agencies. Levee maintenance activities, including vegetation removal and burrow and rodent control on all levees, are permitted under SCVWD's Stream Maintenance Program and are not covered by this Plan. When structural improvements to the levees are required, either for increased flood protection or major failures in structural integrity, the Plan would provide take authorization for this levee reconstruction activity so long as they are part of another covered project such as a flood protection project or described below in this section.

Levee reconstruction activities are those that improve the existing facility through structural changes such as expanding the footprint, increasing the height of the levee, or adding new material to support the levee. Reconstructed levees will generally be constructed with in-kind materials and within the footprint of existing levees. Some changes to levee design and material may be required

based on safety and design requirements. This may include adding new hardscape to the channel banks.

Levee reconstruction areas will be outside mitigation sites associated with this Plan or past projects. No reconstruction or associated clearing of riparian vegetation that provides baseline shaded riverine aquatic cover will be conducted as part of this covered activity. Furthermore, SCVWD is only seeking coverage for reconstruction of 10 of the 23 miles of SCVWD levees in the study area. The levees, or portions thereof, identified below may be reconstructed under this Plan if the Plan requirements for avoidance described in this paragraph and in Chapter 6 are met. Levee reconstruction projects are covered by this Plan only if they are specifically named below or are part of another covered project such as a flood protection project. Although there are a total of 25.1 miles of levees referenced below, this Plan only covers impacts associated with 10 miles of levee reconstruction. See **Table 4-5a** for a description of assumptions made for this covered activity.

## Coyote Watershed

**Berryessa Creek.** Berryessa Creek is an urban creek in the Coyote watershed. It is connected to the Lower Penitencia Creek by an engineered canal. Levee reconstruction will occur between the boundary of the City of San José and Piedmont Road (approximately 0.4 miles).

**Coyote Creek.** Coyote Creek is the main stem of the Coyote watershed. In San José, it is primarily maintained with riparian vegetation on both sides. This vegetation extends into a chain of riverside parks along its upper extent. Levee reconstruction will occur on both sides of the creek in three different locations between the confluence with Upper Penitencia Creek and the northern edge of the permit area, north of (downstream) SR 237 (approximately 1 mile).

**Thompson Creek.** Thompson Creek is an urban stream in the Coyote watershed. It flows through San José constrained by both a natural and modified floodplain. For much of its extent, riparian vegetation lines the banks. Levee reconstruction will occur on both sides of the creek between Aborn Road and Quimby Road (approximately 0.5 mile).

**Upper Penitencia Creek.** Upper Penitencia Creek is in the Coyote watershed. Levee reconstruction will occur to the west of I-680 between Berryessa Road and Mayberry Road (approximately 1.1 mile).

## Guadalupe Watershed

**Alamitos Creek.** Alamitos Creek is a large tributary of the Guadalupe River in the Guadalupe watershed. Riparian vegetation is maintained on both sides as it flows through San José. Levee reconstruction will occur at three separate locations. Levees will be reconstructed along 3.6 miles of Alamitos Creek

upstream of its confluence with Guadalupe Creek (also where Guadalupe River begins).

**Canoas Creek.** Canoas Creek is a tributary of the Guadalupe River in the Guadalupe watershed. Levee reconstruction will occur immediately upstream of its confluence with Guadalupe River (approximately 0.5 miles).

**Guadalupe Creek.** Guadalupe Creek is a tributary of Guadalupe River in the Guadalupe Watershed. Levee reconstruction will occur between where the creek approaches Coleman Road and just downstream of the confluence with Alamitos Creek (i.e., in the initial upstream reaches of Guadalupe River). Total length of levee reconstruction is approximately 1.5 miles.

**Guadalupe River.** Guadalupe River is the major river of the Guadalupe watershed. It is primarily maintained with riparian vegetation on both sides. Levee reconstruction will occur in several locations along Guadalupe River. From the upstream end, the first reconstruction section starts just north and ends just south of where the creek crosses the SR 85. Downstream, a short reach of levee is located just upstream of the confluence of Guadalupe River and Los Gatos Creek, between the I-280 and West Humboldt Street. Finally, levee reconstruction will occur between U.S. 101 and I-880. Total length of levee reconstruction is approximately 2.9 miles.

**Los Gatos Creek.** Los Gatos Creek is a large tributary of the Guadalupe River in the Guadalupe Watershed. It flows through Campbell, Los Gatos and Monte Sereno. Levees are located in three separate locations downstream of Vasona Reservoir and upstream of the San José city limits. Total length of levees is approximately 1.8 miles.

**Randol Creek.** Randol Creek is a highly channelized tributary of Alamitos Creek in San José. It is primarily a trapezoidal earthen channel with periodic concrete structures for flood control purposes. Levee reconstruction will occur on the east side between Camden Avenue and Bret Harte Drive (approximately 0.5 mile).

## Uvas Watershed

**Uvas Creek.** Uvas Creek is the main stem of the Uvas watershed. Levee reconstruction will occur only on the north side of the creek between U.S. 101 and Santa Teresa Boulevard (approximately 2.2 miles) in Gilroy and unincorporated Santa Clara County near Gilroy.

## Llagas Watershed

**Jones Creek.** Jones Creek is a small earthen tributary of Alamais Creek (a tributary to Llagas Creek) in the Llagas watershed. It flows through the agricultural landscape of unincorporated Santa Clara County, east of Gilroy and

west of SR 152. Levee reconstruction will occur on its west side between its confluence with Alamaia Creek between Leavesley Road and Dunlap Road (approximately 0.6 mile).

**Llagas Creek.** Llagas Creek is the main stem river in the Llagas watershed. It is primarily an earthen channel and passes through both unincorporated Santa Clara County and the city of Gilroy. Levee reconstruction will occur on the west side of Llagas Creek from the confluence with the West Branch Llagas Creek north to Gilman Road (approximately 0.8 mile) in agricultural areas.

Levee reconstruction is also planned for lower Llagas Creek between Southside Drive and the creek's confluence with the Pajaro River. Levee reconstruction will occur on both sides of the creek (approximately 2.4 miles).

**Levees near Llagas Creek.** A network of irrigation channels divert water from Llagas Creek in the Llagas watershed. Levee reconstruction will occur on one side between the Pacheco Pass Highway and Bloomfield Avenue (approximately 5.9 miles). These levees do not border Llagas Creek.

**Lions Creek.** Lions Creek is located partially within the planning limit of urban growth of Gilroy. The proposed levee reconstruction would occur just upstream of the confluence with West Branch Llagas Creek (approximately 0.5 miles).

**West Branch Llagas Creek.** West Branch Llagas Creek is a highly channelized tributary of the Llagas Creek flowing through the city of Gilroy. Levee reconstruction will occur on both sides of the creek between its confluence with the main Llagas branch and U.S. 101, predominantly in agricultural areas (approximately 1.1 miles).

## Canal Reconstruction, Realignment, and Decommissioning

SCVWD anticipates needing to fully reconstruct, realign, or decommission its water conveyance canals over the course of the permit term. These canals, their associated diversions, and release points include the following.

- Almaden-Calero Canal
- Coyote Canal Extension
- Cochrane Channel
- Coyote-Alamitos Canal
- Vasona Canal
- Madrone Channel

Coyote Canal may be extended to Metcalf Road by reconstruction in place, or by replacement with a pipeline in the existing alignment or within the alignment of existing multi-use trails in this reach of Coyote Creek. Subsequent phase

activities may include a pipeline to Ford Road Ponds from the Coyote Steel Dam and the Coyote Canal Extension.

Other canals will be reconstructed or replaced with pipelines in the existing footprint of current canals. Canals will be reconstructed of in-kind materials to the extent possible. Depending on the history of erosion in a canal, certain reaches may be reconstructed using gunite or other types of concrete. Most straight reaches without a history of erosion will be of compacted earth. Reconstruction of canals is assumed to result in complete loss of existing, non-developed, land cover types.

SCVWD anticipates possibly decommissioning one or more of its canals. This would be conducted only as needed and when there is a desire to use the canal site for another purpose or to use for restoration credits. Each decommission would be unique, but in general would entail removal of unnecessary concrete and other materials from the site. It is likely that decommissioning would restore canals to an enhanced state for natural resource management purposes; credits for such enhancement are not assumed in the impact analysis in Chapter 4.

## Three Creeks HCP In-Stream Capital Projects

Capital projects associated with the proposed Three Creeks HCP are the seismic safety retrofit of five SCVWD dams in the permit area (Almaden, Anderson, Calero, Guadalupe, and Vasona dams) and the proposed conservation measures in the Three Creeks HCP Conservation Program. Seismic safety retrofit activities are described in the following section *Dam Seismic Safety Retrofit*. The Three Creeks HCP Conservation Program is described in the following section.

## Three Creeks HCP Conservation Program

The proposed Three Creeks HCP includes activities to enhance stream conditions for steelhead, while maintaining use of these watersheds to meet the water supply needs of northern Santa Clara County. The proposed Three Creeks HCP Conservation Program will provide a comprehensive program to address the impacts of SCVWD's operation and maintenance of eight reservoirs (six of which are in the permit area), multiple diversions dams and drop structures and associated facilities (i.e., appurtenances) such as fish ladders, fish screens, and on-channel ponds; an extensive system of off-channel recharge ponds, and facilities that provide for water to be released to various channels. Although fish are not covered by this Plan, covered species such as the California red-legged frog, foothill yellow-legged frog, and California tiger salamander may be affected by implementation of the Three Creeks Conservation Program.

The Three Creeks Conservation Program is still under development by SCVWD; thus, while this Plan provides coverage for covered species that are affected by the activities described below, the discussion of these activities are at a programmatic level. Once the Three Creek HCP Conservation Program has been

adopted the range of activities and impacts will be better understood. Therefore, for specific project impacts that cannot be evaluated, coverage under this Plan would be conditioned upon additional review and approval by the Wildlife Agencies (see Section 8.7.3). The covered activities are described to encompass as much of the activities in the Three Creeks HCP Conservation Program as is currently expected to occur.

The proposed Three Creek HCP Conservation Program includes seven components that will receive take coverage under this Plan.

- Geomorphic Rehabilitation
- Alamitos Creek/Almaden Reservoir Fish Passage
- Gravel Enhancement
- Reservoir and Recharge Re-Operation
- Upper Penitencia Creek Management Program
- Supplemental Flow Program
- Monitoring Program

Geomorphic rehabilitation, Almaden Reservoir fish passage, and the in-stream enhancement program are discussed generally below. Reservoir and recharge re-operation, Upper Penitencia Creek management, supplemental flows, and monitoring are described in Section 2.3.4 *In-Stream Operations and Maintenance* subheading *Three Creeks HCP Conservation Program Operations and Maintenance Actions*.

All construction-type projects will require heavy equipment including but not limited to bull dozers, dump trucks, excavators, backhoes, water trucks, welding equipment, concrete laying equipment, paving equipment, drilling rigs, and other similar equipment. Construction may include transport and use of rock, other soils, concrete, and metals. Following construction, these facilities will require on-going and periodic maintenance similar to the maintenance of recharge facilities described in this chapter.

### **Geomorphic Rehabilitation**

Geomorphic rehabilitation is proposed in the Three Creeks HCP Conservation Program. Under this activity, certain reaches of study area streams below the reservoirs would be substantially modified to improve fish passage. Enhancement may include physical re-configuration of channels, installation of structures to enhance channel complexity (based on CDFG and NMFS guidelines for salmonid habitat enhancement), and riparian planting. Specific projects may include the following.

- Ogier Ponds separation from the channel.
- Coyote Percolation Pond separation from the channel.
- Channel enhancements the Coyote Canal diversion to downstream of Pond 10b, including separation of the channel from Pond 10b.

- Geomorphic rehabilitation in the Coyote Creek Watershed below Anderson dam. Geomorphic rehabilitation entails implementation of actions to enhance the channel for the benefit of anadromous fish (e.g., channel complexity, shading, etc.).
- Geomorphic rehabilitation in the Guadalupe River Watershed below Calero, Almaden, and Guadalupe dams. Project sites include Guadalupe dam to downstream of the Alamitos diversion dam and the upstream end of Almaden Lake to the confluence of Alamitos Creek and Guadalupe Creek.

Upon completion of project construction, sites will be monitored to ensure the actions are successful. If actions are not successful, adaptive management actions may be applied. All actions related to construction, monitoring, and adaptive management are covered activities under this Plan.

### **Alamitos Creek/Almaden Reservoir Fish Passage**

SCVWD proposes to improve steelhead passage to upstream habitat. One of the goals of this program is to isolate juvenile salmonids emigrating downstream from the lake due to threat of predation. SCVWD has not yet identified preferred approaches to achieve these goals. If selected, trapping fish below the dam would require construction of a fish collection facility at the base of the dam. Fish may also need to be conveyed around the reservoir as they migrate downstream. If selected, this option would require construction of a collection facility on Twin Creek, a tributary of Almaden Reservoir. Under this option, SCVWD would construct an operable dam to divert juveniles from the channel to a collection facility. This location would also likely be the site to release adults migrating upstream that were trapped below the dam and trucked around the reservoir.

Because a design has not yet been identified for this project, coverage under this Plan is conditioned upon additional review and approval by the Wildlife Agencies. For the purposes of the impact analysis, a scenario with the greatest impacts to the covered species (i.e., full construction of a new fish ladder and associated facilities in non-developed land cover types) is discussed in Chapter 4 *Impact Analysis and Level of Take* and provided in **Tables 4-5a and 4-5b**. In addition, SCVWD will apply all applicable avoidance and minimization measures as described in Chapter 6 when implementing a fish passage projects.

### **Gravel Enhancement Program**

Installation of gravel traps in the upstream reaches of Coyote, Anderson, Almaden, and Guadalupe reservoirs (below the high-water line) are proposed. The traps are needed to sort and wash gravel to remove fine sediments to improve spawning habitat for native fish. Washed gravel would then be transported to locations beneficial to fish habitat. Excavation may occur a maximum of one time per year per gravel trap if needed, but is expected to generally occur once every 3 years per gravel trap. The need to conduct excavation depends on the number of storms in a given season, how much gravel comes out of the watershed, and the need for gravel enhancement in downstream locations. Excavation will occur in the summer when the reservoir level has

dropped below the location of the gravel trap such that the gravel trap will be dry. If excavated gravel needs to be stockpiled, placement will avoid sensitive natural communities such as wetlands and serpentine grassland. Whenever possible, existing access roads will be used to transport gravel from the excavation sites to processing facilities in the respective downstream watershed.

The following locations are being considered for the gravel enhancement program. One or more of these locations are expected to be selected:

- Anderson Dam to below Coyote Percolation Pond
- Almaden Dam to Lake Almaden
- Guadalupe Dam to the confluence with Alamitos Creek
- Camden Avenue Drop Structure downstream to the confluence with the Guadalupe River

### **In-Stream Cover Enhancement**

In-stream habitat improvements may be undertaken that may include localized installation of boulders, large woody debris, or biotechnical treatments along stream banks to improve cover and riparian functions for salmonids. Activities may also include removal of exotic vegetation and replanting with native riparian vegetation. To implement these improvements, short reaches of channel may require dewatering and bypass of flow around the construction points. For the purposes of the Habitat Plan impacts analysis, a total of 1 mile of stream is assumed to be enhanced with in-stream cover.

### **Fish Passage Enhancement**

The activity incorporates an on-going program to remove small physical and hydrologic barriers to movement of salmonids and other fish and wildlife. Activities include replacement of small culverts with bridged weir structures to provide access to tributary streams. To implement these improvements, short channel segments may require temporary dewatering or bypass to allow construction.

Use of heavy equipment such as bulldozers, dump trucks, excavators, backhoes, water trucks, welding equipment, concrete laying equipment, paving equipment, and drilling rigs may be necessary for these activities.

## **Dam-Related Capital Projects**

### **Dam Seismic Safety Retrofit**

As discussed above in this chapter, SCVWD operates eight large dams and three small flashboard dams in the study area. This Plan covers the retrofit of four SCVWD dams (Almaden, Anderson, Calero, and Guadalupe dams). Other Permittees, including County Parks, and the City of San José, also operate smaller dams. County Parks operates six smaller dams; five on Grant Lake at Joseph D. Grant County Park, and one on Sandywool Lake in Ed R. Levin

County Park. The City of San José operates Cherry Flat Reservoir. All of these dams are operated under regulation by the California DSOD, a division of the California Department of Water Resources. In addition, Anderson Dam is also regulated by the Federal Energy Regulatory Commission (FERC). DSOD and FERC periodically inspect and evaluate the safety of dams based on current seismic safety standards for the design of dams. If either regulatory agency determines that an existing dam does not meet current safety standards, DSOD or FERC may require either dam retrofit or reduction of the level of water in the reservoir to increase freeboard, thus reducing storage capacity.

As dams within the study area age and as safety design standards become more rigorous, it is likely that several regulated dams in the permit area will require seismic retrofitting within the permit term of the Plan. Retrofitting would not require full reconstruction of the dam, but may require extensive upgrades to dam infrastructure such as intakes or outlets. Retrofitting includes the addition of new fill or features to stabilize a structure, with the existing structure remaining either mostly or somewhat intact. Common approaches to retrofit of earthfill and rockfill dams are described briefly below. These approaches can be used individually or in combination for a specific dam.

- **Strengthening the upstream embankment.** Requires raising the dam and increasing the size and slope of the upstream embankment;
- **Strengthening the downstream embankment.** Requires raising the dam and increasing the size and slope of the downstream embankment; raising the dam and bracing the lower portion of the dam with a "bench" or "berm"; and buttressing the embankment.
- **Strengthening the dam internally.** Installing concrete-type cores in the dam to prevent rupture of the internal zone of the dam and seal the foundation.

Given the age of dam facilities, the length of the permit term, and the potential for major seismic events in the Plan study area, it is reasonable to anticipate that some substantial safety retrofits will be required for each of SCVWD's and County Park's dams. Upgrading of dam embankments to meet DSOD-mandated safety standards (safety retrofit) may involve upstream and/or downstream extension of embankments, dewatering of the reservoir (for any safety retrofit requiring work on the upstream embankment), increases in embankment height to increase reservoir freeboard, and reconstruction of the dam face and associated facilities such as spillways and inlet-outlet facilities. For the purposes of the impact analysis described in Chapter 4, it is assumed that four of SCVWD's eight dams in the permit area, the six County Park dams listed above, and the City of San José's Cherry Flat Dam will require retrofit during the permit period.

### SCVWD Dams

Because there are many construction options related to dam seismic safety retrofits, some limitations were identified to qualify for coverage under this Plan. These limitations were developed to allow for reasonable description of the impacts and also to limit the impacts to covered species. The following activities are not covered by this Plan.

1. Seismic retrofit work that is conducted outside of the footprint assessed in the impact analysis (**Table 4-5a**)<sup>11</sup>.
2. Dewatering events longer than 2.5 years at all reservoirs except Anderson for safety seismic retrofit which will not exceed 3.5 years (dewatering events are further described in the following section).
3. More than one dewatering event at a time conducted per watershed (this includes dewatering required for retrofit and dewatering required for activities described under *SCVWD Dam Maintenance Program* below).
4. More than four dewatering events for seismic retrofit (at Almaden, Anderson, Calero, and Guadalupe reservoirs).
5. More than 14 additional dewatering events for other maintenance activities (at all covered SCVWD dams; described below under *SCVWD Dam Maintenance Program*) over the permit term.
6. New earth or rockfill dams.
7. Expansion of design storage capacity or increase in the reservoir surface level as designed (i.e., no additional area of inundation; the crest of the dam might be raised to increase freeboard, but not to increase storage).
8. Dewatering rates inconsistent with **Table 2-4**<sup>12</sup>.

The schedule for each dam seismic safety retrofit is not known at this time. Retrofits on dams that are currently operating under DSOD/SCVWD interim storage restrictions will be initiated according to DSOD requirements and funding constraints. Retrofits will encompass other major dam repairs, including dam outlets and spillways.

Retrofitting four of the eight dams in the permit area operated by SCVWD (all dams except Vasona, Coyote, Chesbro, and Uvas dams), including a dewatering event that is required as part of retrofitting, is a covered activity under this Plan. An increase in existing reservoir size (i.e., increasing the area of inundation or design capacity) is not covered by this Plan.

### **Borrow Sites**

Borrow sites are locations where earth and rock material are removed for construction purposes elsewhere. The materials needed for dam seismic safety retrofits will vary substantially, depending on the type of retrofit. For all retrofits except concrete-type grouting and similar methods, retrofits will require substantial quantities of earth fill and/or rock fill materials including sedimentary soils, rock of various sizes, and concrete. The quantities, quality, and type of materials needed depend on the specific design of the retrofit; materials must meet rigid performance standards in order to ensure safety.

<sup>11</sup> Because the specific retrofit method for each dam was not known at the time of the impact analysis, the impact analysis described in Chapter 4 and **Table 4-5a** assumes that downstream embankment strengthening would be employed for all dams because it represents the worst-case scenario.

<sup>12</sup> The Wildlife Agencies may require adjustments to maximum flows in **Table 2-4** for future projects based on monitoring results (see *Dewatering Event*) below.

To address this fill requirement, SCVWD will consider obtaining fill from a number of sources, including the following.

- The upstream delta of the reservoir.
- The reservoir.
- Existing quarries.
- New quarries in the reservoir basin, in the canyon below the dam, and in the alluvial plain within the Habitat Plan permit area.

Although SCVWD will prefer to obtain materials from sites near the dam and sites with a low potential for impacts to covered species and their habitats, borrow materials must meet engineering criteria for the dam seismic safety retrofit and this requirement will necessarily limit sources for borrow. SCVWD will use the following criteria to avoid and minimize impacts.

- Use fill from the reservoir delta and basin to the extent feasible.
- Select borrow sites based on general feasibility criteria such as suitability of materials, haul distance, cost, and potential impact to covered species. If two or more potential borrow sites are capable of providing materials that meet geotechnical requirements, select the site with the lowest potential for impacts to covered species.
- Avoid wetlands.
- Avoid sites in areas designated as high or medium conservation priority in this Plan.
- Avoid sites within designated habitat preserves.
- Select haul routes to minimize the potential for traffic to impact special status plants and animals.

Borrow sites will not be located directly in streams or immediately adjacent to streams such that permanent stream impacts would occur, except where the stream is also in a reservoir (consistent with the first bullet above). The following worst case assumptions were used to define the maximum allowable impact covered by this Plan.

- Earth fill will be obtained from locations in the alluvial plain in the north valley area.
- Earth fill excavations will range from 30 to 40 feet deep.
- The side slopes of the borrow pits will be 1 (vertical) to 2 (horizontal) and would add 10% to the permanent impact area.
- The area of temporary impact around borrow areas will equal 30% of the area of excavation.
- Rock fill will be obtained from within the reservoir.

Following use of a borrow area in the alluvial plain, SCVWD may use the site as a recharge area (if it is appropriate for recharge) or it may be converted to other uses such as recreation and environmental enhancement.

Borrow sites developed to support reconstruction of dams in the Habitat Plan study area are expected to be located inside of the permit area of the Habitat Plan. Take associated with borrow sites located in the portion of the proposed Three Creeks HCP permit area that does not overlap with the permit area of the Habitat Plan are possible but are not covered activities under the Habitat Plan and would require authorization through the Three Creeks HCP or another regulatory mechanism. Selection of borrow sites located inside the Habitat Plan permit area covered by the Habitat Plan are subject to Wildlife Agency review and approval during implementation of the Plan (see Section 8.7.3 *Wildlife Agency Responsibilities*).

### **Dewatering Event**

Prior to dam seismic safety retrofit, a reservoir must be dewatered. Once emptied, the reservoir is maintained free, or almost free, of water until construction is completed. The reservoir refills the following winter. In the case of a drought, refilling could take longer. The time between the beginning of reservoir dewatering and when the reservoir is re-operated according to applicable rule curves<sup>13</sup> is called a *dewatering event*. SCVWD expects that up to four dewatering events will be required for safety retrofit of the four SCVWD dams covered for this activity. Four dewatering events are associated with seismic safety retrofits, but multiple dewatering events could occur at a single dam over the permit term. In addition, SCVWD anticipates dewatering may be required for some maintenance activities. These activities are discussed in Section 2.3.4 *In-Stream Operations and Maintenance* subheading *SCVWD Dam Maintenance Program*.

Each SCVWD dewatering event is covered under this Plan for up to 2.5 years except at Anderson Reservoir for implementing a seismic safety retrofit. It is expected that Anderson Dam will require two seasons to reconstruct and thus requires 3.5 years for a dewatering event. If SCVWD anticipates a dewatering event will take more than 3.5 years for seismic safety retrofit at Anderson Dam or more than 2.5 years for any dewatering event at other dams, SCVWD will begin a separate consultation process with USFWS and CDFG and may be required to provide additional mitigation beyond that required by the Habitat Plan.

Timing of a dewatering event varies from reservoir to reservoir due to capacity constraints of each dam's outlet system. However, draining a reservoir generally takes months. Construction will be planned so that the reservoir is ready to begin receiving water again in November after construction or maintenance is completed. The reservoir refilling begins during the following (second) season. The amount of time the reservoir requires to refill depends largely on the weather and if the reservoir is a storage facility for imported water. See **Table 2-4** for

<sup>13</sup> There are multiple types of rule curves by which SCVWD operates its reservoirs and not all of them are for species conservation purposes.

maximum covered release flows from reservoirs for the draining phase of dewatering events.

Before a reservoir is dewatered for the first time (whether for dam seismic safety retrofit or other dam maintenance described in Section 2.3.4 below), SCVWD will prepare a reservoir-specific dewatering plan to minimize impacts to covered species (in particular, California red-legged frog and western pond turtle). This plan will be submitted to the Wildlife Agencies for review and approval<sup>14</sup>. Dewatering plans will be updated prior to subsequent dewatering events during the permit term in the event that a single reservoir is dewatered more than once. Dewatering events involve the following components.

- **Draining.** A period generally between 6 months to 1 year of reservoir releases in excess of then-current flow targets. The SCVWD will specify the timing, frequency, and duration of reservoir releases in each dewatering plan.

Maximum covered release flows were developed to be higher than the flows which will be implemented by SCVWD and are provided as a maximum flow release covered by the Plan.

If, at the time of developing a dewatering plan, SCVWD determines the flow releases will be higher than those in **Table 2-4**, additional consultation with the Wildlife Agencies will be required and additional mitigation may also be required.

The effects of stream flow regulation on amphibians and reptiles are poorly understood. If California red-legged frog western pond turtle, or yellow-legged frog populations are found in streams hydrologically affected by existing dams in the permit area, the Implementing Entity will monitor the effects of flow regulation (including dewatering events) on the species as specified in (Section 7.3.3 *Species-Level Actions*). Effects of draining will be documented and reported to the Wildlife Agencies within 60 days of the conclusion of each dry season and wet season dewatering event. After coordinating with the Implementing Entity, the Wildlife Agencies may require an adjustment in the maximum reservoir release flows in **Table 2-4**. For example, if targeted studies show that maximum reservoir release flows allowed during the wet season scoured a significant amount of California red-legged frog egg masses, the Wildlife Agencies may require that the maximum covered reservoir release flow be decreased from those currently specified in **Table 2-4** for future projects on that facility. Conversely, if monitoring data suggests that reservoir release flows described in **Table 2-4** are not having adverse effects on covered species, flows may be increased with Wildlife Agency approval.

- **Construction/repair.** A period of about 6–8 months when the reservoir will be dry, and natural inflow and groundwater upwelling will be bypassed around the dam for release to the downstream channel. The entire footprint

<sup>14</sup> Chapter 6, Condition 4 *Avoidance and Minimization for In-Stream Projects*, subheading *Requirements for SCVWD Dewatering Events* requires a dewatering plan to be approved by the Wildlife Agencies. Condition 4 also identifies the minimum required content of a dewatering plan and avoidance and minimization measures that may be applied. See Chapter 8, Section 8.7.3, subheading *Additional Review* for details of the review process.

of the dry reservoir may or may not be continuously disturbed during this time.

- **Refilling.** A period when the reservoir is re-filling and downstream flow may be limited to a combination of bypass flow and supplemented flow (if supplemental flows are provided) because water levels have not yet reached the elevation of the outlet and to allow the reservoir to fill as rapidly as possible. If there is a dry year following construction/repair, then the period of re-filling may extend beyond one winter season.

Construction and operation of supplemental water supply systems that may be implemented as a covered activity during dewatering events is discussed below under *Three Creeks HCP Conservation Program Operations and Maintenance Actions*.

### County Parks Dams

County Parks anticipates that each lake may require dam retrofit once within the permit term. Up to one dam at Sandywool Lake and up to five dams at Grant Lake may be retrofitted during the permit term. The existing dams are earthen dams. The dam at Sandywool Lake has rip rap armoring to protect from erosion related to wave action. Dams will be reconstructed within the same footprint of the existing dam and will remain earthen unless DSOD requires alternative materials. Repair or maintenance may include embankment strengthening on the downstream side of the dam.

These dams are considerably smaller than SCVWD dams and each dewatering event (i.e., draining, construction, and refilling) is expected to take up to 3 months, although it could be as little as 1 month. Construction will occur during the summer. Lakes will require dewatering prior to construction activities. Work will be performed when each lake is at its lowest level. Sandywool Lake is fed by a pipe from Calaveras Reservoir. Inflows would be shut off at the inflow valve and, through use of reservoir water for irrigation, the water level of the lake allowed to dewater below the level necessary to perform the construction. It is expected that a small pool will be maintained in the lake during construction to support irrigation of park turf and golf courses. Sandywool Lake feeds a small tributary to Arroyo de los Coches, a tributary to Berryessa Creek. While Sandywool dam does have a spillway to Arroyo de los Coches, it does not have outlet valve and does not provide annual flow to local streams. Thus, dewatering is not expected to affect the water supply for local streams.

Grant Lake is fed by overflows from McCreery Lake via a historic canal system. Dewatering would occur by pumping because the lake has no outlet valves. The lake would be dewatered only to the level required to perform the work and a minimal pool will be maintained. Because Grant Lake only receives overflow from McCreery Lake, and McCreery Lake only overflows during winter storm events, no inflows to Grant Lake are expected during the construction period. Grant Lake is not located on a stream, but it does have a drainage connection to Arroyo Aguaque Creek, a tributary to Upper Penitencia Creek, via the dam's spillway. Dewatering is not expected to affect the water supply for local streams.

Both lakes would refill naturally the following winter and through the existing systems supply systems.

Because these reservoirs are relatively small and downstream water supplies are not expected to be affected, dewatering plans for review by the Wildlife Agencies are not required.

Borrow sites will be sited in the California annual grassland land cover type or in other already disturbed areas. Whenever possible, borrow sites will be used to create habitat for covered species (e.g., a pond for California tiger salamander). Location of borrow sites will be within County parks, but exact locations are unknown at this time. Borrow sites will be subject to Wildlife Agency review and approval during implementation of the Plan (Section 8.7.3 *Wildlife Agency Responsibilities*).

### **City of San José Dam**

The City of San José anticipates that the dam at Cherry Flat Dam may require safety retrofit within the permit term of the Plan. Similar to the County Parks dams, this dam is much smaller than the dams maintained by SCVWD. The dewatering event (i.e., draining, construction, and refilling) is expected to take up to 4 months, although it could be as little as 1 month. The reservoir will require dewatering prior to construction activities. Cherry Flat Reservoir is located on Upper Penitencia Creek. This reservoir is not currently managed to support fish flows in Penitencia Creek, although it is managed to maintain minimal flows through Alum Rock Park (approximately 0.5 cfs) during summer months. Reoperation of the reservoir for fish management is included as a conservation measure in the proposed Three Creeks HCP Conservation Program (described below). Because this reservoir is relatively small, a dewatering plan for review by the Wildlife Agencies is not required.

Cherry Flat Reservoir receives water from the upper watershed of Upper Penitencia Creek. The watershed above the reservoir is relatively small (2.4 acres). During a wet year, the reservoir may refill in one season. It may take more than one winter to refill the reservoir during drought conditions.

The borrow site for this project will avoid sites in areas designated as high or medium priority for conservation in this Plan. Borrow sites will be subject to Wildlife Agency review and approval during implementation of the Plan (see Section 8.7.3 *Wildlife Agency Responsibilities* for details).

### **Dam Instrumentation Project**

SCVWD's Dam Instrumentation Project is a capital project that requires installation of new instrumentation at the eight dams in the permit area. This includes the installation of piezometers, inclinometers, survey monuments, real-time monitoring systems, seepage collection systems, reservoir level gauges, and seismographs. Activities also include a field geotechnical exploratory drilling program and providing a corresponding Automated Data Acquisition System for the eight SCVWD dams within the study. Installation of equipment and

exploratory drilling may require access road grading and restoration, drilling, trenching, excavation and backfilling, electrical work, supervisory control and data acquisition (SCADA) system work, and concrete work.

Guadalupe, Anderson, Vasona, Calero Auxiliary dams currently do not have seepage collection systems installed but will likely require such systems to be installed within the permit term. These new systems would be installed within the footprint of the Dam Maintenance Program (described below under *In-Stream Operations and Maintenance*). In addition, any dam that is seismically retrofitted in a downstream direction would require installation of a seepage collection system, although this system would be installed within the footprint of the retrofit.

The work will occur within the identified Dam Maintenance Program footprints and many of the activities associated with this task are also conducted as part of the Dam Maintenance Program. Most of these activities will be conducted on the dams and, to a lesser degree, on the abutments. There is the potential for impact to non-developed land cover. However, because these activities are conducted in the footprints of the Dam Maintenance Program, no additional impacts are assessed for implementation of the Dam Instrumentation Project. Maintenance of dam instrumentation is discussed below in Section 2.3.4 *In-Stream Operations and Maintenance* subheading *Dam Maintenance Program*.

## **In-Channel Groundwater Recharge Facilities**

The following two projects involve rehabilitation and expansion of off-channel groundwater percolation ponds and associated diversions facilities. These systems require: 1) an in-channel diversion dam that pools water, 2) an outlet structure to transport water from the stream channel to the pond, and 3) an off-channel groundwater recharge pond. To provide flow to the off-channel ponds, an in-channel dam is constructed. Historically, this may have included a gravel berm placed across the channel annually, or a permanent in-channel structure. New or replacement temporary diversion structures placed under this Plan will consist of operable (inflatable) dams that can be deflated during times of year when fish passage is most critical. A diversion (outlet pipe or canal) is constructed upstream of the dam in the pool. When water backs up behind the dam, gravity moves water from the pool into the diversion and then into the off-channel percolation pond.

### **Ford Road Groundwater Recharge Pond and New Diversion Dam at Metcalf Road**

SCVWD may propose re-operation of the existing off-stream Ford Road Pond, and expand the site to include up to three additional ponds (for a total of four ponds). Re-operation would only include the existing pond, not the in-channel diversion that was once used to provide flows to the pond. The project site is located between U.S. 101 and Hellyer Avenue, south of Piercy Road and

immediately north of the Coyote Creek Trail, adjacent to Coyote Creek. The project site is approximately 19 acres, including the existing off-channel pond.

As a result of isolating Ogier and Coyote recharge ponds from the main channel of Coyote Creek (a covered activity identified above under *Three Creeks HCP In-Stream Capital Projects*), the area of on-channel percolation will be reduced and SCVWD may need to install a new diversion facility to move flows to off-channel recharge ponds in order to maintain the same level of water diversion to the groundwater basin. If needed, this new diversion would be installed along Coyote Creek at Metcalf Road. In addition, a new pipeline would be constructed that would provide water to the newly isolated Coyote recharge pond and the new Ford Road ponds (both ponds will be served by one diversion and pipeline). The diversion facility may require a seasonal operable (inflatable) dam to create an in-channel ponded area to provide flows to the diversion. If utilized, this dam would also include a fish ladder. Design of the diversion will be coordinated with CDFG for issues related to anadromous fish impacts and because this project will require a streambed alteration agreement. Impacts evaluated in Chapter 4 assume the worst case that a new operable dam, diversion, and pipeline will be installed.

Reoperation of Ford Road ponds is not expected to change flows downstream of the Coyote recharge pond/Ford Road pond complex. If, when the project is ready to be implemented, SCVWD identifies a change in downstream flows due to re-operation of Ford Road pond that may affect the covered species, additional consultation with the Wildlife Agencies will be required that may result in additional minimization and/or mitigation measures.

## Church Avenue Groundwater Recharge Ponds

SCVWD may propose the re-operation of off-stream Church Avenue Ponds. The Church Ponds consist of three ponds located on 57 acres near the intersection of Llagas Avenue and Church Avenue in San Martin. The ponds border the west side of Llagas Creek and are separated from the creek channel by a levee. The ponds have a total surface area of 42 acres. One percolation pond is located directly north of Church Avenue, another pond directly south of Church Avenue, and the third pond is located southeast of the pond south of Church Avenue. The project requires replacement of the existing in-channel diversion along Llagas Creek to supply water to the pond. The final design has not yet been determined, but it may include installation of an operational dam (i.e., inflatable rubber dam) with a permanent fish ladder structure. Design of the diversion will be coordinated with CDFG to address issues related to anadromous fish impacts and to meet the requirements of a streambed alteration agreement.

As described in *In-Stream Operations and Maintenance* subheading *Proposed Operating Rules for Water Supply Facilities in the Uvas and Llagas Watersheds*, Church Avenue Ponds will divert flows from Llagas Creek when reservoir capacity allows, consistent with fish flow and on-channel recharge requirements. Reoperation of Church Avenue ponds is not expected to change flows downstream of the Church Avenue pond beyond that anticipated in *In-Stream*

*Operations and Maintenance* subheading *Proposed Operating Rules for Water Supply Facilities in the Uvas and Llagas Watersheds*. If, when the project is ready to be implemented, SCVWD identifies a new change in flow that may affect the covered species, additional consultation with the Wildlife Agencies will be required that may result in additional minimization and/or mitigation measures.

## **New Bridge Construction and Replacement/ Rehabilitation**

All of the Local Partners operate and maintain bridges within the study area. For example, VTA maintains approximately 10 light rail bridges in San José. The lifespan of a typical bridge is approximately 50 years. Therefore, over the course of the 50-year permit term, it is expected that every bridge within the permit area will likely need major repair or replacement. Similarly, as development within urban areas progresses, new bridges will likely need to be constructed. New and rehabilitated bridges will be designed to federal and state guidelines at the time of construction. In most cases, reconstructed bridges will be wider than the bridges they replace in compliance with changing regulations. Some roads may be widened to accommodate growth in vehicular traffic, bicycles, and pedestrians. Road widening will require adding imported borrow and new asphalt, concrete, and aggregate base for pavement. Where structurally and financially feasible, bridges will be constructed as free-span bridges. Where free-span bridges are not feasible, bridges will be built on pile foundation, cast-in-drilled-hole pile, or spread footing foundations. Excavation for foundations may be required. Slope paving will be included in the scope of work to protect/improve channel slopes at the bridge. County road projects that occur at a stream crossing with a span less than 20 feet are almost always designated as a culvert (D. Cameron pers. comm. a). When culverts are installed, they will be designed and constructed to pass a 100-year flood event as described in Chapter 6. Major bridge repair and rehabilitation may be similar to bridge replacement in scope, often requiring roadway widening, new deck support structures, and seismic retrofitting. The construction of up to 270<sup>15</sup> new bridges, as well as repair and replacement, including expansion, of all existing bridges within the permit area one time during the permit term, is a covered activity of this Plan.

## **Streamside Trails and Crossings**

Several of the Local Partners and the Open Space Authority lead or participate in programs to install trails. New trails are sited outside of the in-stream area to the extent possible to avoid affects on riparian vegetation and streams. However, some trails will need to cross streams and will require installation of bridges or other types of crossings. Trails may also be implemented as a component of

<sup>15</sup> This includes rural residential development but does not include non-bridge creek crossings installed by County Parks along single-track trails.

other types of projects such as flood protection projects or levee reconstruction. In such cases, trails will generally be sited along maintenance roads or in other disturbed areas and will not result in additional impacts beyond those attributed to the main project. The Clean, Safe Creeks and Natural Flood Protection program described above is one such program that supports development of trails into other projects. Streamside trail projects will be a covered activity under this Plan. For more details on trail projects as a covered activity, please see Section 2.3.5 *Rural Capital Projects*.

## 2.3.4 In-Stream Operations and Maintenance

Activities within streams are those activities or projects that occur in or immediately adjacent to streams and adjacent riparian vegetation that may result in impacts on a stream or canal. This may include activities at dams, reservoirs, and on-stream ponds. This category includes operations and maintenance activities in the stream channel, along the stream bank, and adjacent lands at top-of-bank within the riparian corridor, including maintenance of access roads and trails. These covered activities occur in both urban and rural areas. This section discusses operations and maintenance activities in or adjacent to streams.

### Facility and Stream Maintenance

The majority of identified operations and maintenance activities within and adjacent to streams are undertaken by SCVWD, which is responsible for maintaining its facilities. As described earlier, SCVWD is responsible for approximately 35% of the linear distance of all streams within the permit area. As described below, activities conducted by SCVWD under its Stream Maintenance Program are not covered by this Plan and its permits. Specific activities conducted by SCVWD covered under this Plan are described in detail below. Other Permittees also conduct activities within streams, often on properties they own separately. For example, County of Santa Clara Department of Parks and Recreation is responsible for routine maintenance within County parks, including properties leased by the County for parks. The Cities of San José, Gilroy, and Morgan Hill also maintain some stream segments within their jurisdictions. The following operations and maintenance activities within streams are covered by this Plan. Most of the activities listed below will be conducted by the cities, County Parks, the Open Space Authority, and County Roads and Airports Department for stream segments not maintained by SCVWD through the Stream Maintenance Program.

- Facility maintenance such as trail repair; trash removal; installation of fences; accumulated sediment removal (see following section for additional discussion); trail, road, and culvert repair or replacement; and minor bridge repair.
- Storm system maintenance including clearing outlets in order to ensure unrestricted storm water flow. Work may entail trimming vegetation and/or clearing sediment around drain outlets.

- Storm damage repair and flood prevention projects including drainage improvements.
- Natural resource protection such as small bank stabilization projects (less than 100 feet), restoration to reduce erosion, and removal of debris deposited during flooding.
- Small-scale erosion control projects or storm damage prevention projects that do not create new permanent hardscape on the creek bank or channel. This category includes temporary flood-fighting activities to prevent storm damage (e.g., sandbagging).
- Operation and maintenance of flood protection facilities such as armored creeks, bypass channels, levees, access roads, and detention ponds.
- Fish screen installation and removal of fish barriers such as in-stream concrete low-flow crossings and culverts.
- Vegetation management for exotic species removal, such as removal of giant reed, and planting of native vegetation.
- Vegetation management for public safety hazards including fire management and mosquito control activities.
- Stream gauge station maintenance upstream of reservoirs.
- Operations and maintenance of water utility/water supply facilities including flashboard or inflatable dams, diversion structures, groundwater recharge ponds, gauges, pipeline blowoffs, turnouts, drop structures, weirs, fish ladders, etc.
- Sediment removal, including mercury remediation incidental to the sediment removal.

Operations and maintenance activities associated with habitat enhancement and restoration that will be conducted inside and outside the Reserve System are identified in Section 2.3.8 *Conservation Strategy Implementation*.

## Sediment Removal and Mercury Remediation

Removal of accumulated sediment is a covered activity under this Plan. Due to historic mining practices in some portions of the study area, sediment in some of the streams in the study area (e.g., Guadalupe River and its tributaries) may contain detectable levels of mercury. Current regulations require that sediment be tested for contaminants, including mercury, before it is used elsewhere in the watershed or distributed to a landfill. Sediment that tests positive for mercury will be disposed of in a hazardous materials facility. Although mercury remediation is undertaken through some sediment removal projects, mercury remediation is not the primary goal but rather a result of proper and regulated sediment disposal. Sediment removal activities undertaken as part of routine stream maintenance that also remove mercury from streams and are conducted by

Local Partners other than SCVWD are covered by this Plan<sup>16</sup>. Activities undertaken with a primary goal of mercury remediation are not covered by this Plan (see Section 2.4 *Projects and Activities Not Covered by this Plan* for additional detail).

## Santa Clara Valley Water District

SCVWD has in place or is developing other permitting programs to obtain necessary incidental take permits for operation and maintenance activities. In 2002 SCVWD received permits to implement the Stream Maintenance Program which provides ESA coverage for routine stream maintenance (see Section 2.4 *Projects and Activities Not Covered by this Plan* for additional detail). The non-routine stream maintenance activities described below are covered only by this Plan. As discussed above, SCVWD is also currently developing the Three Creeks HCP. Certain activities covered under the Three Creeks HCP are also covered by this Plan as described in this chapter. SCVWD is also currently developing a Dam Maintenance Program (described below). Implementation of the Dam Maintenance Program is a covered activity under both the Three Creeks HCP and the Habitat Plan as pertains to their respective study areas (**Figure 2-5**).

### Reservoir Operations under DSOD Interim Storage Restrictions

As discussed above in Section 2.3.3 *In-Stream Capital Projects*, SCVWD and the DSOD regularly evaluate the status of SCVWD dams to ensure their continued safety. If a potential safety concern is identified, SCVWD reduces storage until the concern can be addressed. Known as *interim storage restrictions*, these voluntary reductions in storage affect water supply operations (management of reservoirs and ground water basins). In particular, they place an increasing emphasis on wet-season recharge so that SCVWD can capture as much inflow from storms as possible and retain as much of the reduced storage capacity of the reservoir for dry season recharge. Most of SCVWD's dams (all but Vasona, Uvas, and Chesbro) have been operating with storage restrictions for approximately 12 years.

As of December 2011, SCVWD and DSOD agreed to increased storage restrictions (additional reductions) on Anderson, Calero, and Guadalupe reservoirs. Storage restrictions were not changed for Almaden and Coyote reservoirs. No interim storage restrictions are currently in place for Vasona, Chesbro, or Uvas reservoirs. Current interim storage restrictions are shown in **Table 2-5**.

From the date that DSOD issues a storage restriction to re-operation of the reservoir post safety retrofit, the process to implement a retrofit may take several

<sup>16</sup> SCVWD's Stream Maintenance Program provides coverage for minor mercury remediation associated with sediment removal.

years due to design review requirements, financing, and environmental reviews; therefore interim storage restrictions are likely to be in place until SCVWD is able to implement repairs to DSOD standards (which may require seismic retrofit).

Over the last 12 years of DSOD storage restrictions, SCVWD has operated some reservoirs according to rule curves for special-status fish species, and SCVWD expects that these requirements will continue (see *Proposed Operating Rules for Water Supply Facilities in the Uvas and Llagas Watersheds and Three Creeks HCP Conservation Program Operations and Maintenance Actions* below). If SCVWD is not able to meet these rule curve requirements, developed in coordination with NMFS and CDFG, due to future increases in DSOD storage restrictions (including new storage restrictions on dams currently without restrictions), and dry-back in channels below reservoirs increases substantially over current conditions, then SCVWD will begin a separate consultation process with USFWS and CDFG and may be required to provide additional monitoring and/or mitigation beyond that required by the Habitat Plan.

## Recharge Operations and Maintenance

In the channels below the reservoirs, SCVWD operates and maintains in-channel and off-channel recharge ponds and associated facilities. SCVWD operates and maintains the following types of facilities:

- In-channel diversion dams, diversions, weirs, and drop structures with associated fish ladders, fish screens, distribution ditches, inter-pond pipes, and recharge basins;
- Streamflow gauges and associated equipment; and
- Pipeline turnouts where water is released into creeks.

This infrastructure is entirely located downstream of reservoirs and dams, or on tributaries of reaches downstream of dams. The operation of this infrastructure may result in small levels of take of covered species and is described below. Maintenance includes inspection, cleaning, periodic sediment removal, debris removal, on-going placement and removal of flashboard panels, and similar activities. Maintenance may be required as a result of flood damage, debris damage, seismic events, or other changed or unforeseen circumstances. These facilities may be modified and may require significant redesign, refurbishment, or replacement once in 50 years. Maintenance, repair, and replacement may involve a range of activity intensities, from minor work in the channel with hand tools to more extensive work that may involve work in the channel and in adjacent terrestrial habitats using construction equipment. During refurbishment and/or replacement activities may include removal of existing structures, excavations, placement of concrete, and re-construction of structures including metal work. These activities may require heavy equipment to access and work in the channel. Permanent access roads will be constructed and maintained, and there will be hardscaped facilities on concrete pads.

Maintenance of facilities includes modification to the facilities, within the construction footprints defined, that enhance safety or operations. In three locations, SCVWD proposes to replace current flashboard dams (which cannot be operated on a daily basis) with operable dams that would allow dams to be raised and lowered on a daily basis without compromising safety. Various configurations will be evaluated. From May 1 through October 31, the operable dams would be used in a manner consistent with current practices; the ability to change dam operations on a daily basis would change operations from November 1 through April 30, when at present the dams are either removed or left in place. This shift in operations would alter hydrology during the period from November 1 through April 30 and would affect the height and configuration of the dams, the depth of ponding, and duration of ponding behind the dams.

SCVWD operates about 320 acres of off-channel and on-channel recharge basins in the Three Creeks HCP study area, and approximately 50 acres in the Uvas and Llagas watersheds. Recharge ponds are generally surrounded by levees or were converted from gravel mining operations and are partially below grade. The ponds are linked to the adjacent channels via weirs and overflow spillway or overflow standpipes and pipelines so that, when necessary, water may be discharged from the ponds to the channel. Discharges are made when inflow to the ponds exceeds the capacity of the ponds, which generally occurs when flow through the ponds is constrained by debris build up at a gate, stormwater overflow, or other problems; the pond elevation rises in response and the water flows through the overflow pipelines or over weirs to the channel. This occurs only infrequently at all locations other than Upper Penitencia Creek, where SCVWD routinely makes releases to the upper ponds from the South Bay Aqueduct and a portion of these releases is then passed through the ponds to the channel for in-channel recharge.

Ponds and associated facilities are maintained routinely; major repair and maintenance typically occurs on a 2–10 year cycle. Rodent control is conducted as needed to protect levees, pond slopes, and access roads. The levees are repaired, the ponds are drained, 2–6 inches of fine sediment on the bottom of the ponds is removed. Pond maintenance includes use of heavy equipment such as scrapers, dozers, back hoes, cranes, loaders, dump trucks, and other earth moving equipment. Spoils are removed and used as fill or disposed of outside of the area. No sediment is released to the channel. The perimeter roads are repaired and graded, the gates are cleaned and repaired, and pipelines, debris screens, and other features are repaired. Repair of facilities such as gates, pipelines, and pumps may require metal work and use of concrete, chemicals, and asphalt.

Vegetation management is also needed on properties adjacent to the percolation ponds. Aquatic vegetation must be controlled within the ponds, and buildup of algal mats must be removed to maintain percolation rates. The entire footprint of the ponds is thus routinely completely disturbed. When ponds are drained nonnative fish, reptiles, and amphibians in the ponds will be removed and disposed and native species may be relocated as described in Condition 4 (see Section 6.4.2 *In-Stream Projects* subheading *Condition 4. Stream Avoidance and Minimization for In-Stream Projects* for additional detail).

In addition to currently operational recharge areas, SCVWD is proposing to re-operate the off-stream Ford Road Pond located on Coyote Creek and Church Avenue Ponds, and to construct up to four new off-channel recharge ponds. The Ford Road and Church Avenue ponds are described above in Section 2.3.3 *In-Stream Capital Projects* and the four new off-channel ponds are described in Section 2.3.5 *Rural Capital Projects*.

SCVWD diversion dams are semi-operable; that is, they have fixed panels (flashboards) that may be removed at times, but the removal process is time consuming and both difficult and a safety concern during high flows. Removing the fixed panels is generally accomplished with a crane operating from the bank and a backhoe or other heavy equipment operating in the channel and removing the panels to the crane. In general, SCVWD removes flashboards prior to the first storm that may pose a flood threat, and the flashboards are then not replaced until the likelihood of major storms has passed. Depending on the magnitude and timing of precipitation, flashboards may be left in place year round in a dry year or, in a wet year, removed early and reinstalled late. When flashboards are removed, diversions are negligible.

Diversions dams are subject to high flows, debris damage, and general wear and tear. Diversion dams are routinely maintained and various components are replaced. It is anticipated that recharge operations facilities will be replaced, on average across all facilities, once during the permit term of the Habitat Plan. Diversion facilities may be reconstructed as operable dams. Operable dams will be either be inflatable (otherwise known as rubber dams) or will consist of panels that can be raised and lowered remotely. Inflatable dams can be operated in “real-time” during the wet season, thus allowing diversions where flooding is not a concern and for conservation purposes (e.g., flushing sediment, allowing fish passage, etc.). Replacement diversion facilities will not have a substantially different footprint (within 10%) from the existing facility nor will replacement substantially modify the maintenance footprint. Operable dams will be constructed on a sloped concrete bench that will be designed to allow fish passage when the dams are down.

Recharge operations require measurement of stream flow at various locations. This is accomplished using a system of stream flow gauges which are simple fixed structures set across the channel. Operation of these gauges involves routine inspection and repair, a relatively low impact operation. Replacement of such small facilities involves more intensive construction work, as described for all facilities above. SCVWD may also install up to 10 new stream gauges to ensure proper management of stream flows. SCVWD has also installed a number of drop structures which are part of the program to reduce flood potential. These can range from vertical concrete walls or stepped facilities. Drop structures are laddered to promote fish passage at some locations. Finally, SCVWD has release valves for a number of pipelines along the channels which function as release points to drain pipelines during maintenance and/or when pipeline pressure increases and must be relieved to avoid pipeline damage. These “blow-off valves” may need routine maintenance. This routine maintenance is also part of the Pipeline Maintenance Program described below under Section 2.3.6 *Rural Operations and Maintenance*.

SCVWD releases imported water at stream turnouts for flow augmentation to Coyote Creek from the Santa Clara Conduit, Los Gatos Creek from the Central Pipeline, and Calero/Alamitos/Guadalupe Creeks from the Almaden Valley Pipeline.

Maintenance work associated with pipelines is part of SCVWD's Pipeline Maintenance Program, described below in Section 2.3.6 *Rural Operations and Maintenance*.

## **Proposed Operating Rules for Water Supply Facilities in the Uvas and Llagas Watersheds**

SCVWD, in conjunction with NMFS, CDFG, and other local stakeholders, has developed a preliminary set of draft principles to guide operation of Uvas and Chesbro dams to benefit steelhead trout (National Marine Fisheries Service et al. 2009). Operations of these dams are considered together because Uvas and Chesbro dams have been operated in tandem and are linked through a gravity pipeline in which water from Uvas Reservoir can be transferred into Llagas Creek to supplement groundwater percolation in that watershed. The overall objective of the operating strategy is to restore and maintain healthy steelhead populations within Uvas Creek, recognizing that Llagas Creek is extremely flow-limited under most years for steelhead production.

One of the outcomes of the draft principles was a detailed set of “rule curves” to guide the operation of these dams and conservation actions implemented for the benefit of steelhead trout.<sup>17</sup> The rule curves identify different release rates depending on how many acre-feet of water are stored in the reservoir at a specific point in time. These curves were derived from the estimated probability of future stream flows expected on any particular date, based on a statistical analysis of historical stream flow data. In wet years, the full range of releases are available to provide for winter attraction, spring out migration (highest fisheries priority), and summer rearing for steelhead trout. Under less favorable hydrologic conditions, the rules allow for the adjustment of releases to meet the remaining flow priorities for steelhead trout. Operating rules provide for water transfers from the Uvas watershed for percolation in Llagas Creek and Church Avenue groundwater recharge ponds only when there is water to meet all flow requirements in Uvas Creek, including adequate reservoir carry over storage for releases into the next season. The modified rule curves were intended to adjust the release schedule of and between the two reservoirs, relative to the historic prescribed operation (defined by a 1956 Memorandum of Agreement with CDFG) to ensure the steelhead population management is optimized between the two systems.

These management activities may have both beneficial and adverse effects on covered amphibians and reptiles and are covered activities under this Plan.

<sup>17</sup> These preliminary rule curves are detailed in the *Proposed Operating Rules for Water Supply Facilities in the Uvas and Llagas Watersheds* (National Marine Fisheries Service et al. 2009). This document has not been formally adopted by SCVWD or approved by NMFS.

- **Timing of Transfers to Llagas Creek.** SCVWD may transfer Uvas Reservoir water to Llagas Creek only if winter, spring, and summer flow targets can also be met in Uvas Creek. Transfers will be delayed to late summer and fall.
- **Smolt Out-Migration.** SCVWD may provide releases from Uvas Reservoir in April and May (depending upon available water on April 1). Flows may be pulsed to improve outmigration. To maintain assurance that summer flows can be met in Llagas Creek, no outmigration pulses of reservoir storage will be made to Llagas Creek from Chesbro Reservoir. Local seasonal runoff and flood management releases will be the source of pulse flow and hydraulic connectivity.
- **Summer and Fall Releases.** Releases of about 14 cfs from Uvas Reservoir maintain flows downstream to about West Luchessa Avenue (with about 2 cfs flow at Miller Avenue). These releases are able to be percolated into the groundwater basin for water supply. Releases greater than 14 cfs usually extend the flow further downstream to areas where percolation does not enter the groundwater basin for use as future water supply. However, the extent of wetted channel produced by different reservoir releases varies with season, due to accretion by tributary and groundwater inflow, transpiration use by riparian and terrace vegetation, and extent of groundwater pumping. Releases can vary with accretion, so that rearing flows are maintained to a specific point on the stream (target is West Luchessa Avenue). Releases will be increased or decreased as necessary to maintain a live stream to that point, rather than providing a constant release that would result in early and late season expansion of the wetted zone and late summer dry backs to a significant portion of the channel.

Releases from Chesbro Reservoir will maintain summer and fall flow downstream to about the Church Avenue percolation facilities. These releases are able to be percolated into the groundwater basin for water supply and maintain a consistent extent of wetted creek for fish during the dry summer months. If reservoir storage is available an additional release or diverted volume can augment flow, in-stream and be diverted into the Church Avenue percolation ponds. The Church Avenue off-stream recharge diversions will be adjusted as necessary to maintain the maximum the extent of flow between the dam and the Church Avenue percolation facilities. All releases are managed by a set of operational priorities that seek to maintain a consistent and sustainable maximum flow extent during the dry summer for fisheries management and water supply.

- **Rearing Habitat Quality.** If storage in Uvas Reservoir is sufficient, SCVWD may maintain summer and fall (June–December) stream flow to West Luchessa Avenue. The extent of wetted stream channel and the flow to the Church Avenue diversion may be reduced compared to the historic channel conditions based on the reduced amount of water available for transfer from Uvas. Augmented flows from Chesbro that are maintained to the Church Avenue percolation facilities and diverted off-channel for groundwater percolation will maintain improved stream conditions relative to flows that only make it to Church Avenue.

- **Winter Attraction Flows.** If rule curves indicate sufficient water, SCVWD may provide for periodic winter pulse releases from Uvas Reservoir of in each winter month (January, February, and March) to provide for adult steelhead attraction and migration. Reservoir operations on Llagas Creek may include winter base flow release management but other than flood management releases do not include specific winter pulse releases from Chesbro Reservoir. The available water is managed to provide reliability of making fall carryover storage target and the highest priority summer, then spring and winter releases to Llagas Creek.
- **Fine Sediment and Flow Attenuation.** SCVWD may, consistent with flood control needs, reduce or eliminate flood releases in order to increase the frequency of moderate floods to scour the channel, transport sediment, and reduce encroachment into the channel by riparian vegetation.
- **Carryover Volume.** SCVWD may maintain a target carryover volume in Uvas Reservoir to provide for winter and/or spring stream flows in drought years. Chesbro Reservoir may be managed to provide reliability in making the carryover storage target and the highest summer, then spring and releases to Llagas Creek.
- **Dry Years.** In dry years not all seasonal stream flow goals can be met. Operational priorities are applied to Uvas and Chesbro reservoir management when insufficient water is forecast to meet flow objectives. The Operational priorities provide an orderly trade-off of life-history support for steelhead trout based on available water and degree of risk to the population management outcomes of the operational rules applied in each system. When necessary, the step-wise trade-off will be managed in a collaborative discussion with the Wildlife Agencies.

## Dam and Reservoir Maintenance

Dams and reservoirs operated by SCVWD, County Parks, and the City of San José require routine and corrective maintenance to ensure their proper inspection, functioning, and safety. SCVWD operates eight dams in the permit area, as well as Coyote Percolation pond. County Parks maintains six dams, one at Sandywool Lake and five at Grant Lake. The City of San José maintains Cherry Flat dam. Dam and reservoir maintenance activities are described below.

The Plan assumes that the entire dam face and abutments will be permanently affected (see Chapter 4 for additional detail on impacts). In addition, vegetation management may be required around the perimeter of the reservoir in areas where the water level has decreased due to annual fluctuations. Removal of debris accumulating at the dam and along the perimeter of the reservoir may also be required. Debris removal may require use of cranes and other heavy equipment operated from the dam and/or in the temporarily dry area of the reservoir that is created by fluctuating water levels.

Reservoirs may also require dredging to remove sediment in order to maintain reservoir function and capacity. This activity will take place within the reservoir

basin and will utilize existing roads and disturbed areas for access and staging. Some reservoirs may have oxygenation systems installed. These systems require routine maintenance and may also require replacement.

For SCVWD, this activity does not include dewatering of the downstream channel except as related to dewatering events as described briefly below and in more detail above in Section 2.3.3 *In-Stream Capital Projects* subheading *Dewatering Event*. For County Parks and City of San José, dewatering of reservoirs is not anticipated beyond normal use and operation of the reservoirs (e.g., typical annual fluctuations in reservoir levels) and is not required for this activity.

### **SCVWD Dam Maintenance Program**

SCVWD's Dam Maintenance Program identifies operations and maintenance activities required to maintain the 10 dams, as well as Coyote Percolation and Rinconada percolation ponds, within SCVWD jurisdiction. Eight of these dams—Almaden, Anderson, Calero (including Calero main, auxiliary, and Fellows Dike), Chesbro, Coyote, Guadalupe, Uvas, and Vasona—and Coyote Percolation pond are located within the study area. Implementation of the Dam Maintenance Program for the eight dams located in the permit area and for Coyote Percolation pond is covered by this Plan.

SCVWD's dams and reservoirs require routine and corrective maintenance to ensure their proper inspection, functioning, and safety. Typical conditions that affect dam safety and function include:

- Normal wear of facilities caused by operational wear-and-tear, corrosion, sediment build up near the dams, scour effects, fire, wind and water erosion, seepage through the dam, wave action, and debris accumulation and other factors;
- Damage due to debris, high flows, seismic events and other factors;
- Damage due to vandalism and other human activity; and
- Damage due to burrowing animals and deep-rooted plants.

SCVWD also needs to maintain reservoir capacity and to provide native gravel for conservation measures in the channels downstream of the dams, and thus needs to establish and maintain gravel/sediment traps and access roads to these facilities in the upper ends of the reservoirs.

SCVWD conducts routine and preventative maintenance at dams and reservoirs on an on-going basis, year round. Some maintenance cannot be accomplished without dewatering the reservoir because it may be unsafe to make required major repairs using divers and repairs may require more comprehensive efforts than can be accomplished with divers, such as replacement of the inlet valves and hydraulic equipment or modification of the inlet/outlet facility itself. When dewatering is required, reservoirs may only require partial dewatering. However, this Plan assumes that all dewatering events include complete dewatering of the reservoir. Dewatering events may require up to 2.5 years.

Routine and preventative maintenance may be intensive and continuous. It is assumed that the maintenance footprint will be altered to a degree that there is no suitable habitat for any of the covered species. Over 85% of dam maintenance will permanently affect:

- The existing dam embankments, both upstream and downstream;
- Abutment areas within 100 feet of the dam face;
- Areas where there are seepage monitoring and control systems, seismic instrumentation and other monitoring equipment, valves and hydraulic lines (sometimes underwater);
- SCVWD-maintained access roads;
- The spillway area; and
- Adjacent areas within 100 feet of the spillway.

Activities may occur along roads leading to or around the dam area and in the reservoir pool area, including the delta at the upstream end of the reservoir. SCVWD may use herbicides and pesticides in accordance with BMPs described in Chapter 6, but shall be responsible for ensuring no take of covered species occurs as a result of herbicide and pesticide uses. Access roads may be paved with concrete or asphalt to manage erosion.

Although maintenance methods may vary seasonally and from facility to facility, the effects of dam and reservoir maintenance are consistent in terms of their purpose and general practices as described below.

### **Vegetation Removal**

DSOD requires that the dam face must be clearly visible so that any erosion, seepage, slumping, drainage, or burrows can be identified and corrected. All shrubs, trees, forbs, and debris will be removed using various techniques including mechanical removal, grazing, and/or controlled burns. Grasses will be maintained at low height. To prevent deep-rooted plants and burrowing animals from compromising dam embankment integrity, trees and deep rooted shrubs will be removed.

### **Seepage Collection System**

Seepage is water that slowly flows through a dam and to the surface usually near the downstream base. This is a common occurrence for earth fill dams, but needs accurate and regular monitoring. A change in the amount of seepage can indicate a change deep within the core of the dam, which may need to be addressed to ensure safety. A seepage collection system is installed to monitor seepage through a dam.

The seepage collection system is a component of the Dam Instrumentation Project described above under *In-Stream Capital Projects*, but it is maintained as part of the Dam Maintenance Program. The seepage collection system consists of several components at the base of a dam which collect seepage and allow accurate measurement of seepage flows through the dam. The components typically include below-grade seepage collection pipes, weirs, weir boxes,

V-ditches, track racks, and an upper graded area to direct the flows to the ditches. Sedimentation occurring over time may compromise the collection function and vegetation growth may prevent visual inspection; thus access for maintenance of the seepage system must be maintained.

Seepage collection system maintenance includes cleaning debris (rocks, vegetation, weeds, etc.) from weirs, erosion repair, grading, repairing concrete, and replacing components. Repairing portions of seepage pipes would include excavation with a backhoe to inspect the pipes, removal of the old pipe, and placement of the new pipe. Grading could be required as well. Seepage control and monitoring would also include installation of new weirs.

### **Burrowing Rodent Control**

Burrowing animals will be managed to prevent the construction of burrows. Management may involve efforts to reduce the populations of burrowing animals such as ground squirrels through use of pesticides<sup>18</sup>, kill traps, shooting rodents with air guns, or non-lead bullets and silencers and/or excavation and re-compaction of burrows that are found on the dam face and abutments. Once initial management is conducted, SCVWD will continue to manage burrows annually. Any burrows encountered subsequent to initial management will be excavated, re-filled, and compacted expeditiously to minimize the potential of creating a population sink for covered species.

### **Maintenance of Access to All Facilities**

Dam and reservoir access roads owned by SCVWD will be maintained including maintaining drainage under these roads. Within the maintenance footprint, road alignments may be changed and new roads constructed.

### **Sediment Management**

It is necessary to manage sedimentation of the reservoir, both to maintain reservoir function (for example, removal of sediment blocking inlets), and to provide a source of native gravels for downstream aquatic habitat enhancement. Accordingly, there will be on-going sediment extraction, sorting, cleaning, drying, stockpiling, and hauling at the upstream end of the reservoir involving the use of heavy construction equipment.

### **Other Management**

SCVWD may re-grade the dam embankment, repair and replace structures on and adjacent to the embankment (such as spillways, power lines, electrical facilities, repair erosion or embankment degradation, monitoring facilities, structures housing operations equipment, fencing, culverts, and other drainage facilities), and manage vegetation for fuels management and for exotic species management.

SCVWD may need to install or repair dam instrumentation other than the seepage collection system which is described above (the Dam Instrumentation Project is described above under *In-Stream Capital Projects*). This includes the repair of piezometers, inclinometers, survey monuments, real-time monitoring

<sup>18</sup> The use of pesticides or herbicides is not a covered activity for the USFWS permit.

systems, seepage collection systems, reservoir level gauges, and seismographs. Seismic investigations may include drilling or digging test pits or trenches. This work will be conducted concurrent with other maintenance activities described above

Major repairs to facilities may involve reservoir drawdown (dewatering) to allow access to facilities, excavation of exposed sediments, and removal of debris using a variety of heavy equipment. During such repairs, sediment may be removed from the reservoir. Based on historic frequency of major repairs, SCVWD projects that its eight reservoirs combined may require up to 18 dewatering events for 7 dams (all SCVWD reservoirs except Vasona which can be dewatered under routine operation practices) over the 50-year permit term. The 18 dewaterings are inclusive of both seismic retrofit activities and other maintenance. Dewatering events may be conducted for one hydraulic system replacement for the upstream valve for each dam (7); one seismic safety retrofit for four dams (4) (Calero, Guadalupe, Almaden, and Anderson); and one other dewatering event per dam (7).

All dewatering events would be planned in advance, require a dewatering plan as described in Chapter 6 that is approved by the Wildlife Agencies, and all releases will be consistent with **Table 2-4**.

## Non-Routine Stream Maintenance

The Stream Maintenance Program permits cover “routine” maintenance, as defined by those permits. The Stream Maintenance Program permits do not cover “non-routine” activities, so these activities are covered by this Plan. Non-routine stream maintenance activities performed by SCVWD for water supply and flood protection are listed below.

- One-time extensive (approximately 50%) vegetation removal, including removal of trees larger than 6 inches in diameter, in the Lower Llagas flood control channel to restore flood protection capacity. This activity is currently outside the scope of the Stream Maintenance Program; however, once this project is conducted and overall vegetation in the channel is reduced, this reach will be maintained under the Stream Maintenance Program.
- Repairs to canals including bank stabilization, sediment removal, and vegetation management not otherwise permitted by the Stream Maintenance Program (e.g., in serpentine vegetation areas and during the wet season). Wet season work would only be required in cases where the canal filled with sediment during winter storms and delaying removal of the sediment until the summer could result in canal failure or flooding of nearby homes.

## Three Creeks HCP Conservation Program Operations and Maintenance Actions

The following actions are proposed by SCVWD as part of the Three Creeks HCP and are covered activities of this Plan. SCVWD will not re-operate its facilities until it receives authorization from NMFS and CDFG. In the Three Creeks HCP study area this will be accomplished through the Three Creeks HCP. In addition to the activities described below, SCVWD will conduct general maintenance of facilities to support the Conservation Program similar to the maintenance actions described in this chapter.

### Reservoir and Recharge Re-Operation

The proposed Three Creeks HCP Conservation Program addresses modifications of reservoir and groundwater recharge operations to enhance flow, temperature, and water quality conditions in the channels downstream of reservoirs to promote better fish habitat. The following activities may be implemented as part of the Conservation Program.

#### Summer Cold Water Releases (May 1 to October 31)

Between May 1 and October 31, SCVWD will provide steady state releases of cold water from the reservoir hypolimnion of Anderson and Guadalupe reservoirs to the creeks downstream of each dam. The average area of this activity (designated as a Cold Water Management Zone or CWMZ) for each creek extends from the reservoir release point to a defined compliance point downstream. The length of the CWMZ will vary depending on the volume of hypolimnion storage and is adjusted once a month during the implementation period.

**Anderson Reservoir Releases to Coyote Creek.** Prior to restoration of Coyote Creek through the Ogier Ponds (a geomorphic rehabilitation activity described above in Section 2.3.3 *In-Stream Capital Projects*), the CWMZ will extend from the base of Anderson Dam to the southernmost pond of the Ogier Ponds Complex. Following restoration of the channel at Ogier Ponds, the compliance point will be the Old Riverside Golf Course (5.5 miles downstream of Anderson Dam). Following restoration of the channel through the Coyote percolation ponds, the CWMZ will be extended by another 3 miles to a maximum length of up to 8.5 miles.

**Guadalupe Reservoir releases to Guadalupe Creek.** The CWMZ at Guadalupe Creek will extend from the base of Guadalupe Dam to Camden Avenue (about 4 miles).

#### Winter Base Flow Releases (November 1 to April 30)

Between November 1 and April 30, SCVWD will provide winter base flows adequate to maintain an 8 inches water depth over at least 25% of critical riffle area for steelhead trout in the channel reaches downstream of the following dams and on-channel structures.

- Almaden Dam, between the dam and Alamitos Diversion (steelhead)
- Anderson Dam, between the dam and Ford Road crossing (steelhead)

- Calero Main Dam, between the dam and Alamitos Diversion (steelhead)
- Camden Avenue Drop Structure on Los Gatos Creek (which is located downstream of Vasona Reservoir)
- Guadalupe Dam, between the dam and Alamitos Diversion (steelhead)

#### **Pulse Flows (February 15 to April 30)**

Upon approval from NMFS and CDFG, SCVWD will provide releases from Almaden, Anderson, Calero, and Guadalupe reservoirs to provide for two 5-day pulse flows each year when reservoir storage is available to do so. In addition, at Anderson Dam, SCVWD will provide releases up to the capacity of the outlet (approximately 550 cfs) to enhance downstream channel and floodplain habitat.

In addition, in upper Penitencia Creek, SCVWD expects to experiment with flow regimes with the intent of increasing the number of out-migrating smolts on Upper Penitencia Creek. This includes working with the City of San José to optimize operations of Cherry Flat reservoir and adjusting the recharge operation with releases from the Bob Gross Recharge ponds. SCVWD will implement a ramping schedule so that releases do not wash native fish or covered amphibians, such as foothill yellow-legged frog, egg sacs and larvae, if present, downstream.

#### **Upper Penitencia Creek Management Program**

The proposed re-operation of SCVWD facilities in Upper Penitencia Creek is intended to substantially isolate the creek from the influence of water supply operations so that these operations have minimal effect on salmonid spawning, rearing, and outmigration. Upper Penitencia Creek re-operation will enhance upstream passage for steelhead and other native aquatic species and reduce the potential for supplemental flows from the South Bay Aqueduct to affect steelhead spawning, rearing, and outmigration.

The program may include the following.

- Removal of the existing Noble Diversions within 5 years of Three Creeks HCP permit issuance.
- Relocation of the Dorel Drive streamflow gauge 200 feet downstream.
- Rededication of SCVWD's existing water right to change the beneficial use to protection of fisheries.
- Isolation of the creek from off-channel recharge operations using screens.
- Management of imported water releases to ensure flow augmentation does not result in the creation of measurable flow at Stream Gauge 87 (the existing Mabury gauge).

#### **Supplemental Flow Program**

To implement the proposed Three Creeks HCP, SCVWD may need to provide supplemental flows to the base of Anderson and Calero Main dams and bypass flows at Almaden and Guadalupe dams to ensure that the conservation strategy flow targets for summer flows can be reliably met under a variety of conditions, such as implementation of DSOD Interim Storage Restrictions, short-term

equipment failures, and scheduled and unscheduled maintenance that requires reservoir dewatering.

Supplemental flows will be supplied by bypassing water around the reservoir using existing or temporary pipeline systems. If other sources of water, such as imported water or recycled water meet water quality criteria, they may also be used. Alternative water sources may be supplied through existing pipelines or through new temporary pipelines. This will require the construction of some new infrastructure to either bypass the flows from above the reservoir or to connect to alternative water supplies. Wells and pumps will be constructed in currently disturbed operational areas and pipelines will be constructed in the public rights of way. Pipelines will be constructed in and along roads, and connected to the channel at the base of the dam via existing operations roads. The footprint of these systems in natural habitats will be not more than 500 feet each. Temporary construction impacts may occur along the channel-side of the roads where the pipelines will be placed.

Temporary pipelines will be installed prior to the completion of reservoir drawdown and when supplemental flows are required. Temporary pipelines will be removed when supplemental flows are no longer needed.

#### **Monitoring Program**

SCVWD will conduct monitoring of species covered by the Three Creeks HCP. The monitoring program will include the same types of activities described below in Section 2.3.8 *Conservation Strategy Implementation*, subheading *Species Surveys, Monitoring, and Research*.

## **2.3.5 Rural Capital Projects**

This category addresses public infrastructure projects outside the cities' planning limits of urban growth. The operation and maintenance of these projects, as well as existing facilities, are described in Section 2.3.6 *Rural Operations and Maintenance*. Activities that are stream oriented and take place mostly within stream channels, such as bridge construction, and that are implemented by the Local Partners are discussed separately in Sections 2.3.3 *In-Stream Capital Projects*, and 2.3.4, *In-Stream Operations and Maintenance*. Rural residential development projects are discussed separately in Section 2.3.7 *Rural Development*. Private rural development, including new bridges installed as part of a rural development project, are discussed in Section 2.3.7 *Rural Development*.

Rural capital projects and activities that are covered under this Plan are listed below.

- Rural transportation projects including bicycle and pedestrian improvements (see description in following section).
- Development of or upgrades to new County Parks' facilities (described below).

- Renovation, replacement, and upgrades of existing facilities.
- Closures of trails, roads, and other infrastructure (such as stock ponds) in public open space (excluding the Reserve System).
- Facility development, renovation, and expansion including offices, office drainage improvements, and visitor centers.
- Water supply projects (see description below).
- Stormwater management facilities including a detention basin proposed by Morgan Hill outside of its planning limits of urban growth.
- Capital improvement projects by County Parks and the Open Space Authority<sup>19</sup> (see description below).
- Kirby Canyon landfill development (see description below).
- Implementation of the South County Airport Master Plan (see description below).

## Rural Transportation Projects

Transportation projects taking place outside of the planning limits of urban growth are included as covered activities in this Plan. Transportation projects within the planning limits of urban growth are considered part of urban development and are discussed in Section 2.3.2 *Urban Development*.

Transportation projects inside the planning limits of urban growth and in in-stream areas (i.e., bridges) are discussed in Section 2.3.3 *In-Stream Capital Projects*. Rural transportation projects provide and enhance infrastructure that supports existing development and new development planned under current general plans. Rural transportation projects and activities covered under this Plan include the following types of projects.

- County and VTA projects outside of the planning limits of urban growth and listed in **Table 2-6**. These include highway expansion, highway intersection upgrades, mass transit projects, and new road connection, extension, widening, and major realignment projects. Projects may include trails for pedestrian and bicycle use.
- County roadway safety and operational improvement projects to roads including shoulder widening and minor straightening of curves, and to intersections and driveway entrances including constructing new turning lanes, adding signals, and lengthening existing turning lanes. Projects may improve access for pedestrian and bicycle use.
- Channel modifications incidental to stream bank stabilization and road restoration.

A road realignment occurs when the position of an existing road is moved to create a more direct travel line (e.g., to eliminate a zigzag or straighten a curve).

<sup>19</sup> The Open Space Authority is participating in the Plan as a Participating Special Entity (see Section 8.4 *Participating Special Entities* for details).

A new connection or extension is when two different roads are connected together where a direct connection did not previously exist. New connections and extensions require up to 92 feet of road width along the length of the project and generally result in the full relocation of a section of roadway (i.e., the road is moved from one place to another). This differs from minor curve straightening conducted as part of safety/operational improvements where the roadway is slightly shifted (up to 8 feet) one way. Minor curve straightening may or may not be conducted in conjunction with shoulder widening.

Incidental take coverage will be limited to the types of projects described in the bullets above and to the specific projects described in **Table 2-6**. Projects described in **Table 2-6** include major County road projects and VTA highway and mass transit projects as described in the VTP 2035. These projects are shown in **Figure 2-7**. Transportation projects led by County Roads or by VTA occurring within the planning limits of urban growth are also shown on **Figure 2-7**, but are covered under Urban Development.

All of the VTA capital projects are proposed along existing transportation corridors and are located on the valley floor. One exception to this is that the U.S. 101 Improvement Project from Monterey Road to SR 129 includes a new extension of Santa Teresa Boulevard from Castro Valley Road to U.S. 101 (0.7 miles). This new alignment also requires a stream crossing. This project extends into San Benito County; only the portion of this project contained within the Permit Area is covered by the Plan.

County Roads has identified three new road extensions or connections in the permit area and outside of the planning limits of urban growth. These projects include:

- a connection of DeWitt Avenue to the West Edmundson Avenue / Sunnyside Avenue intersection near Morgan Hill (0.4 miles);
- a connection on Center Avenue between Omar Avenue and Buena Vista Avenue near Gilroy, requires a new stream crossing (0.2 miles); and
- a connection between Center Avenue and Hill Road across Maple Avenue immediately south of Morgan Hill (0.2 miles).

These projects will be conducted in conjunction with other road improvements. All other projects will occur along existing roads.

Two additional County road extension projects fall within or on the border of the planning limits of urban growth. These include the following projects:

- an extension of McKean Road to Almaden Expressway near the South Almaden Urban Reserve (0.2 miles) inside the planning limit of urban growth for San José; and
- an extension on Hill Road from Half Road to East Main Avenue (0.4 miles) and new connection of Peet Road to Half Road (0.2 miles) inside the planning limit of urban growth for Morgan Hill.

In addition to the projects listed in **Table 2-6**, County Roads anticipates constructing 33 miles of safety and/or operational projects that require widening of the shoulder or minor straightening of curves. These projects would require an additional 8 feet of road width over the length of the project. Up to 25 of the 33 miles may be located in the east or west hills outside of the valley floor area. County Roads also anticipates making 1.5 miles of improvements to roadway intersections and driveway entrances that include constructing new turning lanes, adding signals, and lengthening of existing turning lanes. Intersection improvements require up to 12 feet of additional road width. Up to 0.5 of the 1.5 miles may be located in the east or west hills outside of the valley floor area.

New roads constructed in association with rural development will be installed by the developer and not the County. New roads associated with rural development are described in Section 2.3.7 *Rural Development*.

## South County Airport Expansion

The South County Airport is located within the unincorporated community of San Martin in Santa Clara County. The airport is bounded by U.S. 101 to the east, San Martin Avenue to the north, and Murphy Avenue to the west. A mixture of residential, commercial, and industrial uses surrounds the airport on all sides.

South County Airport is owned and operated by the County of Santa Clara. The airport encompasses 179 acres and consists of a single runway and two parallel taxiways on either side of the runway. A large building area, containing nearly all of the airport buildings, is located west of Runway 14-32.

A new Master Plan for the South County Airport was developed in 2006 (County of Santa Clara 2006c). This plan outlines the expansion and redevelopment of the airport. Actions proposed in the master plan include those listed below.

- Extending the runway.
- Realigning the runway and taxi lanes.
- Constructing a new air traffic control tower.
- Expanding the capacity for hangars, tiedowns, and fixed base operators.
- Expanding fuel storage and dispensing areas.
- Adding wash racks.
- Remodeling airport facilities and terminal buildings including parking areas and access roads.
- Expanding existing stormwater detention basins.
- Replacement of the existing septic system with a package wastewater treatment plant.
- Relocating the existing animal shelter.

- Upgrading lights and signage.

No new land will need to be purchased for the County to develop the master plan elements described above. New lands may be purchased for the purpose of protecting the safety zones around the airport, but newly purchased property would not be used for airport development (Honaker pers. comm.). Projects and activities listed above that are related to the full implementation of the South County Airport Master Plan are covered by this Plan. Environmental compliance (CEQA and NEPA) is expected to be completed in mid- to late 2010.

## Kirby Canyon Landfill Development

The Kirby Canyon Landfill, operated by Waste Management of California, Inc., is located on land leased from Castle & Cook, Inc., at the southern end of Coyote Ridge near Anderson Reservoir. The need for a landfill in this area was first identified in the mid-1970s to support the urban, suburban, and rural growth of Santa Clara County. Currently, the landfill is subdivided into five fill areas and is proposed to affect 311 acres over its entire life. To date the landfill has been partially developed in Fill Area 1. Each Fill Area is composed of “cells.” Fill Areas 2 and 5 are next in the planned sequence of development following the remaining cell development in Fill Area 1. The current lease with the landowner expires in 2034.

An EIR was certified in 1983 by the City of San José for impacts on 484 acres (inclusive of a 326-acre landfill) on an 827-acre site (City of San José 1983). The landfill opened in 1986. The EIR described several sensitive biological resources at the site and required mitigation measures to mitigate the impacts to these species. Although landfill development occurs in phases incrementally over several decades, the mitigation addresses impacts on these resources that are caused by the entire landfill operation. The City of San José has issued a permit for the entire 311-acre landfill (City of San José 1984). Each of the five fill areas at the landfill is subject to subsequent City of San José Planned Development permit reissuance. These subsequent Planned Development approvals allow the City discretionary review of landfill operations, environmental conditions, and mitigation measures over the life of the landfill.

The EIR identified and addressed the following species or habitats of concern on the site: Bay checkerspot butterfly, California red-legged frog, prairie falcon, serpentine grassland plant community, and Mount Hamilton thistle. The biological conditions of approval in the City’s Planned Development permit for the landfill require a program to protect Bay checkerspot butterfly, a program to replace Mt. Hamilton thistle, and a program to preserve California red-legged frog.

In response to the EIR and the project Planned Development permit conditions, a conservation plan was developed by Waste Management in 1985, prior to the listing of Bay checkerspot butterfly, to mitigate the effects of landfill development, operations, maintenance, and closure activities associated with the property. The butterfly was not listed at the time, but it was proposed for listing.

The Federal Highways Administration obtained a conference opinion from USFWS regarding landfill impacts on Bay checkerspot butterfly because the Federal Highways Administration was preparing an environmental assessment on the construction of the Scheller Avenue interchange to serve the landfill. After Bay checkerspot butterfly was listed, the conference opinion was revised into a biological opinion in 1993.

The conservation plan for Bay checkerspot butterfly in the 1993 biological opinion specifies the provisions listed below.

- Management and monitoring of 250 acres of prime Bay checkerspot butterfly serpentine grassland habitat through a lease and control of grazing practices for 13 years<sup>20</sup>.
- A study of revegetation methods for restoring Bay checkerspot butterfly grassland habitat to finished landfill slopes.
- Monitoring of the Bay checkerspot butterfly population.
- Study of possible relocation sites if the onsite mitigation is unsuccessful or the landfill impacts are greater than expected.

Implementation of the conservation plan is overseen by a Board of Trustees that includes a representative from the City of San José, one from Waste Management, and an independent scientist. Annual reports are provided to the Trust regarding the status of implementation of the conservation plan activities. To date, the 250-acre lease area is still managed with grazing; a revegetation plan has been prepared; the butterfly population is monitored annually; and, although offsite areas to relocate Bay checkerspot butterfly were identified, this option was found both infeasible once the butterfly was listed and unnecessary because the landfill had little effect on the stability of the butterfly population.

Subsequent to the conservation plan for Bay checkerspot butterfly, Waste Management obtained permits for filling of wetlands at the site. While Waste Management initially obtained Nationwide Permit 26 authorization for filling 3.62 acres of jurisdictional wetlands and waters of the United States associated with the entire landfill project, for business reasons the company revised its proposal and obtained a permit from the Corps (USFWS Biological Opinion 1-1-97-F-5) for filling up to 1.76 acres, including the landfill and the mitigation area. As a result of that permit process, a Mount Hamilton thistle wetland and breeding habitat for California red-legged frog were successfully established and monitored for 5 years. The California red-legged frog population at the site has been greatly increased, and annual monitoring of California red-legged frog at the site is ongoing.

Waste Management obtained additional permits from the Corps, Regional Water Quality Control Board, and CDFG to complete filling in Fill Areas 1, 2, and 5. A biological assessment was developed (Thomas Reid Associates 2003) and the

<sup>20</sup> Although the biological opinion required management and monitoring for 13 years, Waste Management continues to support an agreement with a rancher to control grazing levels on the 250 acres and the site is monitored annually for the Kirby Canyon Landfill Conservation Trust (Waste Management 2008).

subsequent biological opinion issued for the Corps permit (1-1-03-F-0213; July 2003) addresses California red-legged frog, Santa Clara Valley dudleya, and Bay checkerspot butterfly critical habitat for the entire 827-acre project site. The 2003 biological opinion requires that, upon closure of the landfill, a permanent conservation easement be placed on 300–350 acres of restored landfill for the protection of California red-legged frog. An endowment will be established to provide adequate financing for the perpetual management and maintenance of the conservation easement. Other mitigation includes creating an additional wetland and offsite habitat restoration.

Permits and mitigation for wetland impacts in Fill Areas 3 and 4 of the planned 311-acre landfill have not been authorized.

In summary, USFWS has issued biological opinions providing take authorization for the entire approved landfill footprint for California red-legged frog, Bay checkerspot butterfly and its critical habitat, and Santa Clara Valley dudleya. Mitigation already in place for the entire envisioned and approved landfill footprint includes establishment of new breeding habitat for California red-legged frog, restored upland habitat for the frog, restored serpentine habitat for Bay checkerspot butterfly and rare plants, and funding to provide long-term monitoring and adaptive management of permanent habitat easements (U.S. Fish and Wildlife Service 2003).

USFWS found that the entire landfill development is not likely to jeopardize the continued existence of the listed species or to adversely modify or destroy Bay checkerspot butterfly critical habitat in Unit 8. While the entire landfill project has USFWS authorizations for the species listed above, and local zoning and use permits, future authorization for currently undisturbed portions of Fill Areas 3 and 4 will be required from the Corps and state agencies.

Future development of Fill Areas 3 and 4 at Kirby Landfill are covered activities in this Plan for the covered species not already addressed in the existing biological opinions for the site (i.e., all species covered by this Plan except Bay checkerspot butterfly, California red-legged frog, and Santa Clara Valley dudleya).

## **SCVWD Off-Channel Groundwater Recharge Ponds**

To enhance its water supply infrastructure and to meet future anticipated demand, SCVWD may construct additional groundwater recharge ponds (also called percolation ponds). SCVWD anticipates that up to four new, off-stream groundwater recharge ponds and associated conduits will be installed within the permit area over the course of the permit term. Three of these sites will be located along the valley floor within Morgan Hill and to the south in San Martin. While these sites are in close proximity to Llagas Creek, the ponds will be constructed off-channel. The fourth site will be located near the Cross-Valley Pipeline in the southern portion of the Coyote Greenbelt and will also be off-channel. The three sites in Morgan Hill and San Martin will each be approximately 10 acres in size. The site in the Coyote Greenbelt will be

approximately 15 acres in size. The exact location of the ponds will be identified through future siting studies. However, the approximate locations are shown on **Figure 2-6**. These new off-channel recharge ponds are separate from the reoperation of the Ford Road and Church Avenue recharge ponds described above in Sections 2.3.3 *In-Stream Capital Projects* and 2.3.4 *In-Stream Operations and Maintenance*.

These projects may require installation of piping or a conduit to transport local and imported water to the sites, but will not require any additional in-channel diversions. Sites in Morgan Hill are generally supplied, by pipeline, with Central Valley Project water from San Luis Reservoir. If the Santa Clara Conduit is shut down due to maintenance or inspections, water may be provided by Anderson and or Coyote Reservoirs. The site in San Martin will likely receive water from Chesbro and Uvas Reservoirs via the Uvas/Llagas Transfer Pipeline. The site in the Coyote Greenbelt will likely receive water via the Cross-Valley Pipeline. These projects may also require up to 1.5 miles of new access roads; however, existing access roads will be utilized whenever possible. Construction of these ponds is a covered activity under this Plan.

## County Parks Projects

As guided by the *Santa Clara County Parks and Recreation System: Strategic Plan* (County of Santa Clara, Parks and Recreation Department, August 2003), County Parks continues to develop integrated master plans and natural resources management plans that incorporate recreation, resource planning, historic planning, interpretive planning, operations and maintenance impacts and environmental documentation. To date, County Parks has developed several park and trail master plans and natural resource management plans that it currently implements and will continue to implement throughout the permit term. All of these plans will be updated during the permit term of this Plan to address the on-going and changing operational needs of its parks. In addition, County Parks is developing or plans to develop master plans and natural resource management plans for several additional parks.

To develop the following list of projects and activities, County Parks evaluated past, present, and anticipated activities and projects for which it will require coverage during the permit term. The projects and activities covered by this Plan include the following.

- Trail and fire road development, and installation of related infrastructure such as bridges, staging areas, restrooms, parking lots, and signage.
- Development of borrow sites for materials used for trail structures (e.g., rock) or restoration projects (e.g., clay for wetland substrate). Whenever possible, borrow sites will be used to create habitat for covered species (e.g., a pond for California tiger salamander). Location of borrow sites will be within County parks, but exact locations are unknown at this time. County Parks will avoid sensitive land cover types. Over the permit term, County Parks estimates that borrow sites will require up to 3 acres. Borrow sites will be primarily sited in grassland areas that support conversion to wetland or

pond habitat once borrow materials are excavated. If County Parks creates ponds for the improvement of covered species, soil removed may be stockpiled and stored for future use to reduce the need for additional borrow pits at future times.

- Development of regional recreation opportunities and supporting infrastructure including group and family picnic areas, drive-in campgrounds, back-country camp areas, a regional swimming facility, nature/education centers, historic and cultural resources, disc golf courses, an 18-hole golf course and club house, sport fields, off-leash dog parks, dog runs, road and mountain bicycle park, fishing ponds, events pavilions, shade structures, hang gliding/paragliding landing sites, urban edge farming, historic agricultural park, agricultural marketing area (i.e., expanded produce stand, farmers market area, retail café, and parking), community gardens, research and demonstration gardens, youth agricultural areas, staging areas including restrooms, equestrian staging areas including water troughs, parking, operations and maintenance facilities and buildings, park ranger facilities, multiple use areas, public art installations, gateway sites (e.g., trailheads, park entrances, kiosks), paved and dirt roads, seating (e.g., benches), landscaping, fencing, irrigation, water tanks, interpretive signage, sewer, water, and other utilities.
- Capital improvements to existing trail systems including reconstruction, realignment and, in areas where the use is compatible, the addition of separate single-use trails (e.g., equestrian trails). These improvements also include trail restoration in areas where abandoned trails are no longer in use.
- Capital improvement expansion or rehabilitation of existing facilities including campgrounds, equestrian camping sites, day-use picnic sites, staging areas, parking, restrooms, entry and gateway sites (e.g., trailheads, park entrances, kiosks), buildings, landscaping, irrigation, fencing, interpretive signage, sewer, water, and other utilities.
- Restoration, creation, enhancement, and/or rehabilitation of habitat including riparian, wetlands, ponds, grassland, and oak woodland natural communities outside of the Reserve System (restoration and enhancement within the Reserve System on County Park lands is described in Section 2.3.8 *Conservation Strategy Implementation* below).
- Installation of fish screens at Parkway Lakes, Cottonwood Lake, and Spring Valley to prevent movement of fish in and out of these lakes and to support recreational fishing opportunities.
- Construction of stock ponds or spring boxes<sup>21</sup> for cattle management and installation of wells to supply stock ponds outside of the Reserve System (restoration and enhancement within the Reserve System on County Park lands is described in Section 2.3.8 *Conservation Strategy Implementation* below). Spring boxes will be preferred over wells. Up to 40 wells or spring boxes may be constructed for use in County parks. Wells and spring boxes will be sited so that they do not degrade surrounding habitat.

<sup>21</sup> Spring boxes are boxes or culverts installed into the ground to provide water through a series of pipes to a tank or directly to a trough for recreation or cattle management.

- Reconstruction of pond dams or spring boxes to maintain water levels and facility functioning.
- Replacement of the water delivery system at Jackson Ranch. This includes excavation and replacement of the existing system.

Intensive recreational uses or facilities (e.g., golf courses, regional sports complexes, sports fields, pavilions, nature centers, off-leash dog parks) generally are planned to occur in the valley floor area closer to urban and rural centers. Facilities planned in the near and far hills will focus on less intensive recreational uses such as trails and back-country camping sites.

County Parks estimates it will construct outside of the planning limits of urban growth no more than 20 miles of fire road; 25 miles of unpaved, single-track trail; 3 miles of paved service roads; 7 miles of paved multi-use trail; and 10 miles of paved roads. This does not include roads and trails that are part of a larger site development (e.g., nature center, large picnic areas, pavilions, golf course, etc.). County Parks estimates it will construct outside of the planning limits of urban growth up to 300 non-bridge water crossings (e.g., single-track trail crossings), 20 large bridges (i.e., one-or two-way automotive use), and 30 small bridges and puncheons (i.e., footbridges). County Parks estimates it will conduct larger-scale site development projects (e.g., nature center, large picnic areas, pavilions, golf course, etc.) outside of the planning limits of urban growth requiring approximately 1,700 acres.

## City of San José Projects

Alum Rock Park Riparian Management Plan provides a management strategy to protect and restore the riparian and aquatic resources along Upper Penitencia Creek within this 740-acre Park (Biotic Resources Group 2001). The Riparian Management Plan provides a comprehensive set of goals, policies, and management actions that integrate watershed resources and reflect the unique quality of the park's riparian and aquatic resources. This management document is focused on enhancing and restoring Upper Penitencia Creek with Alum Rock Park.

Activities that will be conducted under this plan include the following.

- **Hillside instability and landslide prevention.** Measures to reduce the potential for mass wasting this include the repair of eroded area and revegetation of exposed areas. Activities may also include improvements to hillside drainage by installing additional culverts along localized roads and trails.
- **Streambank erosion.** Consider setting back the existing bank and recontouring the slope to reduce existing erosion issues. Projects may include enhancing the channel bed to provide pooling areas and vegetative cover along the channel.

- **Riparian and aquatic habitat restoration and enhancement.** Revegetate the sediment bar and other degraded areas adjacent to the stream channel to restore a riparian corridor. Create new and expand the existing floodplain and side channel habitat.
- **Facility upgrades.** Relocate existing picnic area approximately 20 feet outside of the riparian corridor.

## Open Space Authority Projects

As described above, the Open Space Authority owns and manages several properties in the study area. Although not a Permittee, the Open Space Authority has requested that their activities within the permit area be covered by the Plan if they choose to seek this coverage as a Participating Special Entity (see Chapter 8, Section 8.4 *Participating Special Entities* for this method of coverage).

The Open Space Authority will be developing use and management plans for each property to address protection of natural and cultural resources; opportunities for appropriate visitor access and passive recreation; environmental education and outreach; site safety; and maintenance and operations. These plans will be updated over the course of the permit term, and new use and management plans will be prepared for additional properties that are protected by the Open Space Authority.

Open Space Authority staff evaluated typical open space preserve management projects and activities that occur on existing land holdings, as well as those that are anticipated to occur on future land holdings, in order to identify projects and activities that will require coverage by this Plan. These include:

- Construction and maintenance of visitor amenities including parking areas, roadside pullouts, trailheads, and associated restrooms, picnic areas, shade structures, interpretive facilities, signage, landscaping, and utilities. Construction or repair of existing structures for use as nature centers, hostels, education facilities, or staff support facilities.
- Construction and maintenance of new multiple-use trails with associated bridges, culverts, fords, or other water crossings, and armored surfacing where necessary to accommodate those with disabilities. Installation of signage, benches, and facilities such as back-country campsites and interpretive displays.
- Construction and maintenance of necessary agricultural infrastructure including farm stands, community gardens, research and demonstration gardens, fencing, gates, stock ponds, developed springs, water tanks, and irrigation and drainage infrastructure.
- Maintenance of existing roads including repair, replacement, and installation of bridges, culverts, and other road drainage structures. Decommissioning and restoration of former logging or ranch roads that are no longer necessary for safety patrol, fuels management, or recreational purposes. Realignment

or construction of new roads when necessary to replace poorly located roads that are impacting the environment.

- Development of facilities for management and administration of open space resources including field offices, corporation yards, on-site employee housing, and storage facilities.
- Implementation of resource management and monitoring programs such as restoration, creation, and/or enhancement of habitat including riparian, wetlands, ponds, grassland, mixed evergreen, and oak woodland natural communities. Typical resource management programs include grassland management utilizing cattle grazing and prescribed fires; eradication of invasive plant and animal species, herbicide use, and integrated pest management projects; wildland and urban-interface fuels management including prescribed fires, grazing, and shaded fuel breaks; in-stream and riparian habitat restoration; signage and fencing to protect and/or interpret cultural sites; and implementation of road and trail best management practices to reduce erosion and sediment delivery to watercourses.

## 2.3.6 Rural Operations and Maintenance

This category addresses the rural operations and maintenance activities to be covered under this Plan. Operations and maintenance activities within streams are described separately in Section 2.3.4 *In-Stream Operations and Maintenance*. Rural operations and maintenance activities outside of streams that may receive coverage under this Plan include the following.

- Utility line or facility operations and maintenance as described below.
- Facility maintenance including vegetation and infrastructure management.
- Pond maintenance outside the Reserve System.

### Utility Maintenance

Public and private utility infrastructure such as electric transmission lines, gas pipelines, petroleum pipelines, telecommunications lines, and cellular telephone stations cross the study area. Public and private utilities that are Participating Special Entities (see Section 8.4 *Participating Species Entities*) may request coverage under the Plan for routine maintenance and repair of existing utilities within the permit area. Maintenance activities will generally require trenching around existing pipelines and conducting repairs or replacing segments of pipeline. Coverage for these projects will be decided on a case-by-case basis by the Implementing Entity and Wildlife Agencies. This will allow alternative maintenance approaches, if possible, to avoid or minimize impacts on covered species and natural communities.

## Facility Maintenance

Facility maintenance refers to maintenance of existing facilities such as buildings, roads, trails, parking lots, and airport property. A large component of this maintenance is vegetation management. Vegetation management includes fuel reduction using prescribed burns, grazing activities, exotic vegetation control/removal, hazardous tree work, abatement of hazardous vegetation, and algae control in ponds. Vegetation management also includes turf management, paving, and landscaping around infrastructure and facilities.

Facility maintenance also includes the maintenance of infrastructure such as buildings, roads, utilities (septic, water, power systems), and stormwater treatment. Rodent, pest, and invasive plant species abatement activities may also be conducted for facilities maintenance.

## Pond Maintenance

Pond maintenance on private lands outside the Reserve System is a covered activity if the project proponent receives a ministerial or discretionary permit for this activity from the County or one of the participating cities and complies with the management actions below in addition to the conditions and application processes described in this Plan (see Chapter 6). This covered activity is designed to provide an alternative permitting mechanism for maintenance of stock ponds, but it may support other pond maintenance needs as well. Removal of existing stock ponds is not covered under pond maintenance.

The following management actions are consistent with the conservation strategy management actions for ponds described in Section 5.3.7 *Wetland and Pond Conservation and Management*.

### Required Management Actions

- All vegetation removal will occur after the breeding season for pond-dependent wildlife, including nesting migratory birds.
- If vegetation targeted for removal includes nonnative vegetation on which covered species rely for habitat (e.g., tricolored blackbirds nesting in Himalayan blackberry), the removal will be undertaken in phases over a 3- to 4-year period and replaced with similar, native vegetation suitable to the site.
- If the pond is located in modeled California red-legged frog habitat, vegetation management activities may only occur between August 30th and October 15th.
- If the pond is leaking, repairs will be made to improve water retention and duration.
- All invasive or predatory non-native species (e.g., bullfrogs, mosquitofish, and nonnative predatory fish) will be removed and disposed of by a qualified

biologist. Management techniques described in **Appendix K** *California Tiger Salamander Hybridization*, will be implemented, as deemed appropriate by the project proponent in coordination with the Implementing Entity.

- If the pond is creating or contributing to local erosion, fixes will be made to eliminate the ponds contribution to such issues.
- If needed, dredging will be conducted during the non-breeding periods of covered and other native species (e.g., tricolored blackbird, California tiger salamander, California red-legged frog, or western pond turtle).
- Any disturbed areas will be re-seeded with native vegetation appropriate for the surrounding natural communities for replacement of lost ecological services and function.
- Any herbicide application conducted in ponds or wetlands must use products that have been approved for aquatic communities.
- Grazing rotation and targeted fencing will be used to maintain appropriate vegetation in and around the pond and to reduce existing or potential erosion issues.

### Recommended Management Actions

- If a pond dam requires reconstruction, consider increasing the spillway elevation to increase pond capacity and improve water duration if appropriate<sup>22</sup>.
- If the pond lacks vegetation, consider native plantings where appropriate, after consultation with the Implementing Entity.
- Coarse woody debris or anchored basking platforms may be installed in ponds to improve habitat for western pond turtles (Hays et al. 1999).

Activities conducted by individual Local Partners are identified below.

## Santa Clara Valley Water District

SCVWD operations and maintenance activities outside of streams (i.e., in upland areas) that will receive coverage under this Plan include the following.

- Operations and maintenance of pump stations, operations yards, utility yards, and corporation yards including storing sediment, and truck access.
- Off-stream groundwater recharge sites and associated facilities. Activities may include removal of sediment and vegetation and maintenance of associated roads, diversion structures, and catwalks. See Section 2.3.4 *In-*

<sup>22</sup> In some cases, increasing the spillway elevation may not be appropriate because increasing the inundation period may facilitate the persistence or introduction of non-native species that have detrimental effects on covered species.

*Stream Operations and Maintenance* subheading *Recharge Operations and Maintenance* for additional detail.

- Maintenance of water supply facilities including buildings, rain gauges, pipelines, and turnouts (Pipeline Maintenance Program is described below).

## Rain Gauge Maintenance

SCVWD maintains 39 rain gauges throughout the County. These gauges have a footprint of 9 inches in diameter and are generally located in the upper watershed. Maintenance includes spraying herbicide around the base of the gauge, trimming and/or removal of small to large trees affecting the “catch” of rainfall (i.e., the ability to capture rainfall unobstructed), and trimming of vegetation along access roads to reduce fire hazards. Maintenance may also include modification and/or reconstruction of existing rain gauges. During maintenance a radius of approximately 3 feet is cleared all around the gauge. Rain gauges are accessed from the nearest road. Maintenance of rain gauges is a covered activity under this Plan.

## Pipeline Maintenance Program

SCVWD developed the Pipeline Maintenance Program document (Santa Clara Valley Water District 2007a) and issued the Pipeline Maintenance Program Final EIR (Santa Clara Valley Water District 2007b) in September 2007. SCVWD owns and/or maintains several pipelines and pipeline facilities throughout the study area. These pipelines are located in both unincorporated and incorporated areas of the permit area. However, because the majority of impacts associated with implementation of the Pipeline Maintenance Program will occur in rural areas, the program is discussed in this section.

To address maintenance for these pipelines, SCVWD developed the Pipeline Maintenance Program to establish a process for conducting routine water-conveyance-system maintenance activities within its jurisdiction. The work area subject to the Pipeline Maintenance Program includes the areas around water conveyance systems facilities, including pipelines, pump stations, blow-offs, turnouts, and vaults. The project area also includes the streams, fields, storm drains, and channels where discharge of water during pipeline draining can occur. Pipeline maintenance activities also occur off-stream within urban areas, however, those activities are expected to have much less impact on covered species within urban settings. Additionally, all types of urban operations and maintenance programs are addressed in the urban development category.

Facilities owned and/or operated include the following pipelines and components.

- Almaden Valley Pipeline.
- Anderson Force Main.

- Calero Pipeline.
- Campbell Distributary.
- Central Pipeline.
- Coyote Pumping Plant.
- Coyote-Madrone Pipeline.
- Cross Valley Pipeline.
- East Pipeline.
- Main Avenue Pipeline.
- Milpitas Pipeline.
- Mountain View Distributary.
- Pacheco Conduit and Pacheco Tunnel.
- Pacheco Pumping Plant.
- Parallel East Pipeline.
- Penitencia Force Main.
- Rinconada Force Main.
- Santa Clara Conduit and Tunnel.
- Santa Clara Distributary.
- Santa Teresa Force Main.
- Snell Pipeline.
- Stevens Creek Pipeline.
- Sunnyvale Distributary.
- West Pipeline.
- Uvas-Llagas Transfer Pipeline.

The Pipeline Maintenance Program defines a comprehensive approach to managing the environmental impact of maintenance. The Pipeline Maintenance Program specifies protocols for management and maintenance crews from different divisions working on the same activity to conduct the operations, including the environmental commitments, associated with that work.

In developing the Pipeline Maintenance Program, it was SCVWD's intent that the program and mitigation defined in the Pipeline Maintenance Program serve as the basis for state and federal permits and permit conditions; therefore, regulatory agencies were consulted early in the Pipeline Maintenance Program definition process.

The routine maintenance activities described in the Pipeline Maintenance Program address both raw and treated water pipelines. Over 125 miles of pipeline support delivery of local and imported water in the County. Activities

covered by this Plan include the following. If excavation is required for the activity, it is noted below.

- Cathodic protection and monitoring. Cathodic protection is typically applied to a pipeline by applying small electric current that overdrives or redirects the natural corrosion process, controlling the natural decomposition process of steel to iron-ore. This is accomplished through the use of inexpensive sacrificial metals such as magnesium or zinc electrically attached to a pipeline or by forcing an electric current with an external power supply. Cathodic protection systems are monitored frequently to adjust them to varying soil environments, water tank levels, coating deterioration, and external construction. Where sacrificial metals are employed, routine monitoring is necessary to determine the sacrificial metal's condition and future replacement.
- Leak repair. May require blow-off—dewatering of pipes that typically includes a point sources of high velocity flow—to local uplands or streams and/or excavation to access pipelines. The schedule for leak repairs is variable, guided by the results of monthly visual inspections made by helicopter. The Pipeline Maintenance Program requires a *Water Discharge Definition Plan* for this activity. A *Water Discharge Definition Plan* would describe the total volume discharge water and flow rate, nozzles, vaults, blowoffs, and dissipaters to be utilized.
- Internal inspection. May require blow-off to local uplands or streams. Internal inspections are planned at 5–10 year intervals for each pipeline. Certain facilities (Santa Clara Tunnel, Pacheco Tunnel, and Calaveras fault crossings) once every 5 years. This activity requires a *Water Discharge Definition Plan* (see above bullet for description).
- Unscheduled releases of water due to a pressure surge in a pipeline that could damage pipeline. Under such conditions, an automatic turnout valve will open and release the water to prevent the pipe from bursting. Flows from the pipeline may be reduced following such an event. This type of event is only expected to occur at two facilities located along Los Gatos Creek, the receiving body for these releases. This would occur infrequently, but there is no data system associated with these valves, thus SCVWD does not know exactly how often this occurs. The valves would open for less than one minute and would shut as soon as system pressure dropped.
- Rehabilitation and/or replacement of pipeline components including but not limited to air release valves, piping sections or connections, joints, and appurtenances. Activities may include excavation to access pipelines.
- Bank stabilization and erosion control within creek related to pipeline maintenance. Discharges either come out of pipes within a stream bank and flow down the bank into the channel, or are pumped down or across a stream bank. Bank protection work would occur prior to a planned discharge in areas where banks within 50 feet of the discharge point show signs of erosion or instability. May require excavation.

- Replacement/repair of buried service valves (including valves within creek embankments that may require excavation and minor bank stabilization activities).
- Maintenance of pipeline turnouts, including access to pipelines.
- Replacement/repair of appurtenances, fittings, manholes, and meters.
- Vault maintenance. Vaults occur along segments of pipeline. Pipeline components are located within vaults. There are different types of vaults and all are considered confined spaces. Structures other than the pipeline contained within vaults include valves, electrical stations, turnout piping, etc. Telemetry pull boxes, corrosion monitoring stations, and some air release valves are not located within vaults. Vaults are typically made of concrete and may be located immediately below grade (below ground level) or partially or fully above grade.
- Telemetry cable/system inspections and repairs. Telemetry systems allow communication of data from the pipeline to SCVWD so that they can track the operations of the pipeline. Telemetry cables are generally sited in the center of roads. May require excavation to access system components.
- Meter Inspections and repairs. Flow meters measure the rate of flow through a pipeline. Some meters are located in vaults while others are not.
- Maintenance of pump stations, operation yards, utility yards, and corporation yards.
- Maintenance of pump stations, operation yards, utility yards, corporation yards, vaults and turnouts includes vegetation management. This task may be accomplished through chemical and/or mechanical means depending on the sensitivity of the regional habitat.
- Access road repairs. Excavations of various sizes are often needed to maintain the access roads. Excavation may be required to fill pot holes, conduct drainage and erosion control, conduct shoulder and slope repair, or regravels existing access roads. Access road excavations could be very small (e.g., to repair a pot hole or shoulder slump), or involve larger, linear excavations (e.g., to install or replace culverts or drainage ditches, repair slope failures for elevated access road fills).

This is the general list of activities that are necessary to maintain proper function of all pipelines within SCVWD system. Each of these activities includes additional subtasks, which are the individual steps involved in completing the overall activity.

As noted above, blow-offs are sometimes required to repair or inspect a pipeline. If available, SCVWD directs released water into available turnouts such as off-channel recharge ponds. If not available, water may also be directed to local waterways, storm drains, other urban drainage channels, open fields, or wetlands. Discharge into waterways is accomplished first by gravity flow and then by pumping out residual water. Flow rates can be controlled manually to be between 0–20 cfs for gravity flow blow-offs by manipulating valves. Maximum pump capacities range from 3.3 to 11 cfs. The discharge rate is ramped up

slowly such that the buildup of water in any streams, rivers, or canals is gradual and scouring of the channel bed and ground surfaces does not occur. Discharge to wetlands is generally avoided (it may require additional regulatory permits), although it is sometimes necessary. Discharge to dry soil is also avoided and is not common for large volumes of water (see Chapter 6, Condition 5 for additional stream avoidance measures for pipeline maintenance activities).

The Pipeline Maintenance Program Final EIR identifies direct permanent and temporary impacts from activities grouped into the categories of staging, off-road access, pipeline drainage, excavation, and repair. Impacts are assessed based on assumed for annual maintenance activities. Consistent with two key assumptions of the EIR, this Plan would cover the effects associated with the maintenance of up to 5 pipelines each year. It would also cover up to a total of 10 blow-offs (scheduled and unscheduled) each year. See Chapter 4 for additional detail related to the impacts of this activity. Pipeline Maintenance Program activities outlined above that fall within the permit area may receive coverage under this Plan.

## County of Santa Clara

Rural operations and maintenance activities conducted by the County of Santa Clara outside streams that may receive coverage under this Plan are listed below.

- Maintenance, repair, and rehabilitation of County roads and road shoulders, including pothole repairs, overlays, resurfacing of existing paved areas, construction of retaining walls to stabilize adjacent embankments, vegetation removal (e.g., overhanging bushes, trees), and re-grading to maintain a functional shoulder.
- Maintenance of infrastructure associated with roads including drainage ditches, culverts, and retaining walls.
- Operations, maintenance, and fire protection of rural juvenile detention facilities (e.g., James Ranch and Muriel Wright Center), medical treatment facilities (e.g., Mariposa Lodge), the Santa Clara County Justice Training Center (also known as Holden Ranch), and the Santa Clara County Weapons Training Center (also known as the Sheriff's Firing Range).
- Operation, maintenance, and management of County parks including trail and road maintenance, facility maintenance, vegetation management around structures.
- County Parks management of natural resources including grassland, oak woodland, and riparian natural communities; protection and enhancement of freshwater resources; erosion control; sensitive species management and monitoring outside of the Reserve System (restoration and enhancement within the Reserve System is described in Section 2.3.8 *Conservation Strategy Implementation* below). Management may include prescribed burns, mechanical fuel removal, invasive vegetation management, manual labor, herbicide use, bullfrog management, feral pig removal, management of other exotic nuisance species, and managed grazing.

- County Parks management and maintenance of ponds and spring boxes including temporary draining for amphibian management, dredging or clearing of debris and sediment for water management for cattle, and rehabilitation due to erosion and/or pond or box failure. This does not include pond removal.
- County Parks dam maintenance including burrow management, vegetation removal, dam repairs, and dam facility repairs (short of dam reconstruction which is described above in Section 2.3.3 *In-Stream Capital Projects*).
- Removal of infrastructure (e.g., building structures, roads, trails, stock ponds) for public safety, resource protection, and park management. County Parks may remove up to four stock ponds that do not provide habitat for covered species. Ponds that do provide habitat for covered species may be considered on a case by case basis by CDFG and USFWS.
- Use of County parks consistent with park management plans. Uses vary by park but may include walking, hiking, horseback riding, biking (road and mountain), fishing, swimming in designated swim facilities, recreational sports, nature watching, horse-drawn carts, drive-in camping, equestrian camping, back-country camping, on- and off-leash dog areas. Coverage is only provided to County Parks for the indirect effects of allowable recreational uses.
- Vegetation management for exotic species removal and native vegetation plantings including the use of livestock grazing and prescribed burns.
- Trail maintenance including grading, clearing, brushing, erosion control, paving, re-paving, abandonment, and restoration.
- Pest abatement to manage rodents, insects, and disease, and weed abatement to manage fire hazards outside the Reserve System including removal of dead and dying wood, trees, and vegetation in agricultural areas. May include mowing or disking for weed abatement and spraying for insect and disease management. Use of rodenticide is not covered by this Plan for the USFWS permit.
- Surveys and monitoring to support management decisions outside of the Reserve System (monitoring within the Reserve System is described in Section 2.3.8 *Conservation Strategy Implementation* below).
- Enhancement and restoration projects outside of the Reserve System.
- Removal of fish barriers (such as low flow crossings) and installation of fish screens.
- Maintenance of water delivery systems (e.g., at Jackson Ranch). This includes maintenance of in-stream structures that have a screened pipe that pulls water from a local stream into the property.
- Activities associated with the maintenance of large facilities including golf courses, large event facilities, and sports complexes.
- Equestrian facilities and uses including equestrian stables, equestrian centers, trails, manure management, equestrian group camping and horse grazing activities.

- Minor remediation projects (less than 1.0 acre) for spills, illegal dumping, fuel/chemical storage, and firing ranges.

## Open Space Authority

Operations and maintenance activities conducted by the Open Space Authority in all of their preserves (both existing preserves and preserves acquired during the permit term that are located within the permit area) are covered by this Plan if they choose to seek this coverage as a Participating Special Entity (see Chapter 8, Section 8.4 *Participating Special Entities* for this method of coverage).

Maintenance activities may include the following.

- Vegetation management, including fuel reduction using prescribed burns, grazing activities, exotic vegetation control/removal, hazardous tree work, abatement of hazardous vegetation, and algae control in ponds.
- Invasive wildlife species management, including feral pig and bullfrog management.
- Restoration, rehabilitation, and enhancement, not including removal, of existing stock ponds that have degraded due to severe erosion or dam failure.
- Creation of new ponds to support livestock grazing or wildlife.
- Spring development, including installation of a spring box, and repair of existing spring boxes.
- Road and/or trail closure or realignment due to erosion problems or close proximity to sensitive land cover types.
- Use of Open Space Authority lands outside of the Reserve System consistent with their management plans (activities within the Reserve System are described below). Uses vary by park but may include walking, hiking, biking (road and mountain), horseback riding, and nature watching. Coverage is only provided to the Open Space Authority for the indirect effects of allowable recreational uses.
- Activities associated with the maintenance of facilities including small structures, paving, and landscaping.
- Maintenance of infrastructure facilities including buildings; roads (paved and unpaved); and utilities (septic, water, power systems).

### 2.3.7 Rural Development

Rural development includes private development that will occur in accordance with existing general plans at the time of permit issuance. This includes activities that are subject to a ministerial or discretionary approval by the County or cities. Most of this type of development is expected to be residential development in areas outside the planning limits of urban growth. This generally occurs in the unincorporated county, but some development may occur within

city limits. For the three cities, San José has the most potential for this type of development in its hillside-designated areas that lie outside of the planning limit of urban growth but within the city limits. Gilroy and Morgan Hill may have some of this type of development as well. Rural development may occur in areas designated in **Figure 2-2** as rural residential or ranchland/woodland land use categories. Rural development is also anticipated in agriculture land use areas as is currently allowed and identified in local general plans.

Rural development activities covered by the Plan are listed below.

- Commercial, industrial, institutional, and recreational development in unincorporated areas of the county, including San Martin, consistent with the County General Plan (County of Santa Clara 1994). This includes County projects at the Mariposa Lodge, James and Holden Ranches, and Muriel Wright Center.
- New intensive agriculture and related activities that require discretionary approval consistent with local general plans, such as mushroom farms, commercial stables, equestrian event facilities, and wineries.
- Rural residential development (e.g., single family homes, subdivisions) consistent with the County General Plan (County of Santa Clara 1994). This may include privately owned bridges, driveways, access roads, vineyards or orchards, and other features commonly associated with rural dwelling units.
- Rural residential development on the non-urban hillsides of eastern San José (outside the planning limit of urban growth) and in the Coyote Valley Urban Reserve and South Almaden Valley Urban Reserve consistent with the San José General Plan.
- Rural residential development in the Morgan Hill Southeast Quadrant consistent with the Morgan Hill General Plan.
- Rural residential development in the Hecker Pass Specific Plan area consistent with the Gilroy General Plan.
- Non-residential development in rural areas that requires approval from the County or cities, such as telecom facilities and small utility outposts. Solar energy projects in rural areas are covered by the Plan as long as their impacts to covered species and natural communities are consistent with the effects evaluation in Chapter 4.

Three projects covered under this Plan in accordance with the first item above are described below.

**Expansion of the Z Best Composting site located at 980 SR 25 south of Gilroy.** The owner, Zanker Road Resource Management, is proposing to expand the composting facility. Preliminary site plans show an expansion of approximately 63.4 acres at full buildout. The expansion plan is divided into four phases.

- Phase 1 expansion of 26.1 acres.
- Phase 2 expansion of 14.0 acres.

- Phase 3 expansion of 11.4 acres.
- Phase 4 expansion of 6 acres.

This project will also include construction of a sedimentation basin of 5.9 acres. The project area is surrounded by agricultural land uses.

**Expansion of the existing Pacheco Pass Landfill located at 3675 Pacheco Pass Highway east of Gilroy.** The landfill is operated by Norcal Waste Systems; the existing use is a composting facility and landfill. This project is currently undergoing CEQA review with the County. The project proposes to expand the facility to construct a 48,160-square-foot (<1-acre) transfer station to house local solid waste and recycling. The transfer station will utilize about 5.25 acres of the approximately 60-acre existing site, excluding use of an access road currently used for the composting and landfill operations on site.

**Expansion of the Freeman Quarry.** The existing Freeman Quarry has been proposed to be expanded. The quarry is located at 3201 Monterey Road on Castro Valley Ranch. The quarry is operated by Granite Construction Company on lands owned by Castro Valley Properties, Inc., and is located approximately 5 miles south of Gilroy. The project is proposed as a 90-acre expansion of the existing 61-acre quarry (final size = 151 acres). The expansion area is proposed to include 56 acres for mining or ancillary uses and 34 acres for overburden placement. The quarry would expand to the north and west of the existing quarry. Overburden would be placed at the far northern end of the expansion area.

Implementation of this project includes the following operational requirements.

- During the rainy season (October 15 through March 31) night hauling activities will not occur between 1 hour before sunset and 1 hour after sunrise if rain is falling. "Rainfall" shall be defined as a measurable amount (0.01 inch or more) of liquid precipitation as measured at the NOAA gauge located in Gilroy, California. If a "chance" of rain, defined by NOAA as >50% probability, is forecasted within 24 hours of scheduled night hauling operations (sunset to sunrise), then all night hauling operations shall be canceled and shall not be recommenced or rescheduled until after sunrise. It is assumed that if rain falls at some time during a calendar day during the rainy season, then the chance of rain is over 50% and night hauling operations will not occur.
- Nighttime lighting during the rainy season will be directed away from habitat for covered amphibians.
- Continue to maintain existing ponds on the project site. Maintenance may include periodic draining of ponds to manage exotic species.

## Private Development Subject to the Plan

All private development activities, including rural development, will be subject to all applicable Plan conditions and fees if they meet the criteria described above

in Section 2.3.2 *Urban Development* subheading *Private Development Subject to the Plan*.

## 2.3.8 Conservation Strategy Implementation

In addition to the projects described above, the Plan will provide take authorization for projects and activities associated with implementation of the Plan's conservation strategy as described in detail in Chapter 5 and summarized below. Most of these activities will take place within the Reserve System assembled by the Plan. Some conservation activities may also occur outside of the Reserve System on public or private lands (see Chapter 5 for a description of all conservation actions).

All conservation actions will take place within the Habitat Plan permit area and the Expanded Study Area and permit area for Burrowing Owl Conservation (**Figure 1-2**), except for the possibility that land will be acquired at the mapped boundary of the Habitat Plan permit area. On parcels acquired for the Reserve System that extend beyond the mapped permit area boundary, management, restoration, and monitoring activities are covered on the entire parcel within unmapped portions of the permit area as long as more than half of each parcel is located within the permit area. These covered activities would occur on no more than a total of 250 acres.

## Management Activities

This category includes all management actions required by the Plan or other actions that might be necessary to achieve Plan biological goals and objectives. This category includes construction, maintenance, and use of facilities needed to manage the Reserves, including but not limited to Reserve field offices, maintenance sheds, carports, roads, bridges, culverts, fences, gates, wells, stock tanks, and stock ponds. All Reserve management structures will be constructed to minimize impacts on covered species and vegetation communities and in compliance with the conditions on covered activities described in Chapter 6. Facilities existing at the time of land acquisition will be used whenever feasible.

Management actions that will be used within the Reserve System are described in detail in Chapter 5 *Conservation Strategy*. Actions not already described earlier in the chapter may include but are not limited to the activities listed below. Many of these activities overlap.

- Vegetation management using livestock grazing, manual labor, and/or prescribed burning. Pesticide use is permitted under the Plan only to achieve biological goals and objectives (e.g., exotic plant or exotic animal control), in accordance with label instructions, and in compliance with state and local laws. Pesticide use is covered only under the NCCP Act permit, not the ESA permit. Implementation of integrated pest management programs established by the local jurisdictions is only a covered activity if pesticides are used to

achieve exotic plant or exotic animal control. Any pesticide use must comply with all existing injunctions related to the use of pesticides. For example, the October 2006 stipulated injunction disallows the use of certain pesticides within habitats and buffer zones established around certain habitats for California red-legged frog and the May 2010 stipulated injunction disallows the use of certain pesticides within habitat and buffer zones established for California tiger salamander, San Joaquin kit fox, and Bay checkerspot butterfly.

- Seed collection from covered plant species for depositing in a seed bank.
- Development of field facilities for workshop space and tool and machinery storage.
- Construction, rehabilitation, and maintenance of facilities (e.g., corrals, fencing, gates, feed storage, water delivery) to support livestock grazing as a covered species management tool.
- Maintenance of existing roads and of new roads constructed for the Reserve System, including grading and relocation of roads to protect sensitive resources.
- Translocation of covered species. See Chapter 5 for details.
- Demolition or removal of structures, roads, or man-made livestock ponds to increase public safety or to restore habitat.
- Use of motorized vehicles for patrolling, maintenance, and resource management activities in the Reserve System.
- Use of mechanized equipment for construction, maintenance, and resource management projects in the Reserve System
- Control of nonnative species (e.g., feral cats and dogs, nonnative pigs, red fox, nonnative fish, bullfrogs, barred tiger salamanders, and hybrids<sup>23</sup>).
- Management activities for burrowing owls such as population augmentation, and owl relocation for conservation purposes.
- Stream maintenance for habitat purposes.
- Installation of wells, the water from which will be used to fill stock ponds or provide water sources for cattle. Up to 49 wells will be installed and placed in close proximity to ponds that they will serve. Wells will be installed only as necessary for natural resource management purposes and when no alternative surface water supplies are available. Wells will be sited so that they do not affect seeps or springs and will not degrade surrounding habitat.
- Surveys and monitoring for mitigation and restoration/habitat enhancement projects.
- Fire management including prescribed burning, mowing, and fuel-break establishment and maintenance.

---

<sup>23</sup> See Chapter 5, Section 5.4.2 and **Appendix K**.

- Hazardous materials remediation, such as appropriate closure of underground storage tanks, soil remediation, cleanup of illegal dumping, etc.
- Repair or replacement of existing facilities damaged by floods fire, or earthquake.
- Operations related to water delivery for ponds and other aquatic habitat.
- Water delivery for use in operations facilities (e.g., field facilities and the native plant nursery).

Access to the Reserve System to conduct maintenance, as well as habitat enhancement, restoration and creation projects, will likely require the construction of new roads and bridges. This Plan covers the construction of up to 40 miles of new dirt road and 5 new vehicular bridges within the Reserve System over the permit term. It is not expected that many areas of paved roads will be necessary in the Reserve System and as such, no assumptions for paved roads are included in the impact analysis. However, if the Implementing Entity determines that a certain area requires paving, this would be covered under the Plan, up to 5 miles. To support maintenance activities, it is assumed that approximately 1 well per 1,000 acres of Reserve System will be required and that 53 miles of new fencing will be constructed.

## Public Access and Recreation in the Reserve System

Limited public access and recreational use of Plan reserves is permitted under the guidelines of this Plan (see Chapter 6 for details). To the extent possible, recreational facilities will utilize existing infrastructure such as existing trails and fire or ranch roads. The construction of up to 126 miles of new trails and 25 new trail creek crossings within the Reserve System is assumed in the impact analysis. One new trailhead facility, up to 5.0 acres each, is assumed for every 5,000 acres of newly acquired lands in the Reserve System (not including existing open space incorporated into the Reserve System), resulting in approximately seven new trailhead facilities or 35 acres. It is estimated that new signage will affect 0.25 acre per 1,000 acres of Reserve System.

Covered activities also include the construction and maintenance of recreational facilities such as trails, creek crossings for trails, parking areas, gates, fencing, signage, restrooms, wildlife observation platforms, and educational kiosks that are built and/or used in accordance with the guidelines in this Plan. The Permittees are covered for incidental take of covered species resulting from appropriate public use of trails and parking lots within the permit area, inside or outside of the designated Reserve System, provided that usage is consistent with the guidelines in this Plan. The permits do not cover off-trail recreational activities or any type of activity prohibited by this Plan or by state or federal law.

Up to eight new staging areas, eight new small day-use picnic areas, and three new small backpack camps and their associated staging areas may be allowed within the Reserve System. Picnic areas shall be limited to eight standard picnic benches, restrooms, potable water and trash receptacles. Up to three new

backpack camps to provide low-use, remote camping opportunities within the Reserve System are also covered. These camps will provide restrooms, potable water and trash receptacles.

## Habitat Enhancement, Restoration, and Creation

The Plan conservation strategy (see Chapter 5) sets forth requirements for habitat enhancement, restoration, and creation. Enhancement activities generally fall under the reserve management category. Habitat restoration and creation will generally be disruptive only in the short term because these activities may involve soil disturbance, removal of undesirable plants, and limited grading. All habitat restoration and creation is expected to result in a net long-term benefit for covered species and natural communities. However, these activities may have temporary or short-term adverse effects and may result in limited take of covered species (see Chapter 4 *Impact Assessment and Level of Take*). All habitat enhancement, restoration, and creation activities conducted within Plan reserves that are consistent with the requirements of this Plan are covered by the permits. Habitat enhancement, restoration, and creation activities may also be conducted outside Plan reserves. If such activities occur and are consistent with this Plan, they are covered by the permits. Examples of such activities include restoration projects conducted as mitigation that require additional coverage beyond the self-mitigating aspects inherent to most mitigation projects or restoration of unauthorized trails outside of the Reserve System. Examples of habitat enhancement, restoration, and creation activities include, but are not limited to, the following.

- Pond creation.
- Restoration projects in streams, riparian areas, wetlands, and uplands.
- Native vegetation planting.

## Species Surveys, Monitoring, and Research

Biologists will need to conduct surveys for covered species, natural communities, and other resources within the Plan reserves on a regular basis for monitoring, research, and adaptive management purposes. These surveys may require physical capture and inspection of specimens to determine identity, mark individuals, or measure physical features, all of which may be considered take under ESA or CESA. Surveys for covered species will also be conducted on private land being considered for acquisition for the Plan. Although these surveys are not expected to require as much handling of specimens, take may still occur. Surveys for all covered species will be conducted by qualified biologists, as defined in Chapter 6. All such survey activity consistent with this Plan is covered by the ESA and NCCP permits.

Research conducted by biologists on Plan reserves in support of the Plan is covered by the permits as long as the research projects have negligible effects on populations of covered species. These researchers must be under legal contract

with the Permittee(s) and/or have a Section 10(a)(1)(A) recovery permit to cover incidental take that may occur as a result of research conducted on reserve lands (see Chapter 6 for a more detailed description of a “qualified biologist”). Research on Plan reserves unrelated to the Plan is not covered by the permits because the nature and impacts of these future research projects cannot be predicted at this time. Such researchers would be granted access on a case-by-case basis and such access will be conditioned on compliance with stated restrictions. Research conducted outside of the permit area in support of the Plan’s conservation strategy is also not covered by the Plan (e.g., translocating western burrowing owls into the study area from outside the study area). This research will require coordination and possible permitting from the Wildlife Agencies.

## Emergency Activities

An emergency is a situation involving disasters, casualties, national defense, or security emergencies and includes response activities that must be taken to prevent imminent loss of human life or property (U.S. Fish and Wildlife Service and National Marine Fisheries Service 1998). The Wildlife Agencies will not obstruct an emergency response decision made by the Permittees, where human life is at stake. With the exception of changed circumstances addressed in Chapter 10 *Assurances* take associated with emergencies are not covered by the Plan and associated permits.

Responses to changed circumstances within Plan reserves that may affect populations of covered species are covered under this Plan. Foreseeable emergency activities include, but are not limited to, the following.

- Firefighting of small wildfires or structure fires.
- Evacuation of injured persons or livestock.
- Remediation and cleanup of spills or illegal dumping.
- Remediation, cleanup, and restoration of illegal cultivation activities (e.g., marijuana farms).
- Use of motorized vehicles and mechanized equipment for conducting emergency activities.
- Repair of existing facilities damaged by floods, fire, earthquakes, or other natural disasters.

Responses to emergency activities that have substantial effects on covered species (e.g., firefighting for a large wildfire or repair after a major flood) are considered changed circumstances and are described in Chapter 10.

## Neighboring Landowners Protection Program

The implementation of conservation measures described in Chapter 5 *Conservation Strategy* may increase populations of covered species within Plan Reserves. As a result, some individuals may disperse to neighboring private lands where the presence of listed species could interfere with routine agricultural activities. Protections for neighboring landowners are described in Chapter 10; the methods for establishing and estimating take associated with this program are described in Chapter 4. With certain provisions and restrictions, farmlands within 1 mile of the Reserve System boundary are eligible for take coverage during the course of routine agricultural activities, during the permit term, and for take beyond the baseline condition that existed prior to the establishment of the neighboring Plan reserves. Take coverage for this program is limited to three covered species: California red-legged frog, California tiger salamander, and western pond turtle. For definitions and details of this program, see Chapters 4 and 10.

## 2.4 Projects and Activities Not Covered by this Plan

As described above, this Plan strives to cover all projects and activities for which the Permittees envision the need for incidental take coverage over the permit term. However, certain projects and activities that may occur in the permit area over the permit term are not appropriate for coverage under this Plan due to a variety of factors including, but not limited to, lack of information, speculative nature of the project, existing permits, obtaining permits under a separate program, or the risk that the project or activity is incompatible with the Plan's conservation strategy. The projects and activities listed below were considered, but rejected for coverage under this Plan.

- **Private sector activities that do not obtain a development, grading, building, or other construction permit.** Construction permits involve land disturbance for the purposes of making land improvements, such as the construction of buildings, roads, and driveways ("building permits" referenced herein do not include plumbing, electrical, or mechanical permits). Activities that do not obtain these development permits are not covered by the Plan.
- **SCVWD Stream Maintenance Program.** The Stream Maintenance Program was developed to streamline the permitting process for routine stream maintenance activities, thus allowing SCVWD to continue preserving the existing level of flood protection of streams and water-delivery function of canals in the County in an efficient manner. The Stream Maintenance Program was authorized in 2002 and the impact analysis of the program was based on a 20-year study period. Permits received under the program include: Section 7 biological opinions from NMFS and USFWS through the Section 404 Permit, CDFG 1601 Streambed Alteration Agreement, Regional Board Waste Discharge Requirements Permits (Central Coast and San

Francisco Bay Regional Boards), and a San Francisco Bay Conservation and Development Commission (BCDC) permit.

The Stream Maintenance Program provides coverage for the following activities on streams for which SCVWD has maintenance responsibilities.

- ❑ Vegetation management for in-stream and upland areas. Management is done using herbicide and mechanical techniques.
- ❑ Sediment removal to return engineered channels to as-built conditions.
- ❑ Bank protection for erosion control.
- ❑ Minor maintenance activities that avoid significant impacts requiring mitigation. This category includes such activities as graffiti removal, repair of structures with in-kind materials within the existing footprint, and tree pruning along maintenance roads and fence lines to provide access and to remove hazards.

Under the Stream Maintenance Program, routine maintenance is undertaken with consideration of special-status species that may be affected by the activities. Detailed BMPs were developed (and are continually updated through adaptive management) to reduce impacts from program activities, including potential impacts on special-status species. Even after application of BMPs, the program results in significant impacts. Thus, SCVWD is responsible for mitigation associated with its maintenance activities.

As mitigation for the Stream Maintenance Program, SCVWD proposed and obtained approval for a mitigation package that includes restoration of 30 acres of tidal wetlands, creation of 14 acres of freshwater wetlands, purchase of approximately 1,000 acres in the upper watershed areas for stream and watershed protection, and implementation of 125 acres of giant reed (*Arundo donax*) control including removal and follow-up monitoring and removal. Lands restored or purchased will be preserved in perpetuity as open space. In addition, mitigation for bank protection projects is calculated separately for each project. Mitigation is based on the table of ratios in Appendix E of the Stream Maintenance Program document.

The Stream Maintenance Program provides incidental take coverage for five federally listed species, three of which are also covered by this Plan<sup>24</sup>. Existing permits also address impacts on waters of the United States and waters of the state. The current permits are written for 10 years, expiring in 2012. However, the program is anticipated to provide regulatory coverage for federally listed species through 2022. At that time, additional impact analysis of activities would be required to determine whether new significant impacts would result from ongoing routine maintenance. This analysis is needed for negotiation of extensions for the Stream Maintenance Program permits. Because these activities already have endangered species coverage under the Stream Maintenance Program permits, they do not require coverage under the Habitat Plan and will therefore not be covered by this Plan.

<sup>24</sup> Bay checkerspot butterfly, California red-legged frog, least Bell's vireo, salt marsh harvest mouse, and western snowy plover are covered by SCVWD Stream Maintenance Program; the first three are also covered by this Plan.

- **City of Gilroy expansion beyond the Plan's planning limit of urban growth.** The Gilroy General Plan (2002) (City of Gilroy 2002a) designates a number of areas outside the 20-year planning boundary as future areas for development and open space (W. Faus pers. comm.). Policy 2.11 of the Gilroy General Plan designates two areas outside its 20-year planning boundary (the boundary used as the planning limit of urban growth for the purposes of this Plan) as potential areas for future development. These areas are described below.

- The area north of Day Road, west of Santa Teresa Boulevard, and east of the foothills. This area is suitable for long-term residential expansion and related development.
- The area east of U.S. 101 between Buena Vista and Masten Avenue, bordering on the highway. This area is suitable for long-term expansion of highway-oriented commercial development.

Impacts associated with expansion of urban development into these areas were not assessed for this Plan and are not a covered activity of this Plan.

- **Bay Area to Central Valley high-speed train.** The Federal Railroad Administration and the California High Speed Rail Authority are currently planning the San Francisco Bay Area to Central Valley portion of the California High-Speed Train System (70 FR 71370–71372). The proposed alignment for the High-Speed Train System through Pacheco Pass traverses the Plan study area. It is possible that portions, or all, of this alignment could be constructed during the permit term. In such a case, this project would not be covered under this Plan.
- **New highway between I-5 and U.S. 101.** The Metropolitan Transportation Commission's 2030 Regional Transportation Plan lists a "limited-access 4-lane facility and partial new alignment between I-5 and U.S. 101 (possible toll road)" (Metropolitan Transportation Commission 2005). The Regional Transportation Plan does not discuss this project in any detail but provides a preliminary budget of \$432 million. Should this project be pursued during the life of the Plan permit, it would not be covered under the Plan.
- **Routine and ongoing agricultural activities.** Routine and ongoing agricultural activities that do not go through a County or city permitting process (e.g., a grading and/or building permit) would not be subject to local approval and therefore cannot be covered by the Plan. Routine agricultural activities are defined broadly as activities that occur in the normal course of existing farming or ranching operations, including crop planting, crop harvesting, livestock management, and pesticide application. These activities are not covered by the Plan, with the exception of the Neighboring Landowners Protection Program described above and in Section 10.2.7 *Assurances for Private Landowners*.

New intensive agricultural activities such as cut flower nurseries, Christmas tree farms, ornamental plant nurseries, dairies, and feedlots are not covered by this Plan unless these activities receive permits from the County. The conversion of agricultural lands to non-agricultural uses are covered by this Plan as described above in this chapter.

- **Expansion of cultivated agriculture into natural lands.** The expansion of cultivated agriculture into natural lands (as defined by the natural land cover types described in Chapter 3) is not covered by this Plan unless it receives a development or grading permit. This category typically applies to new large-scale agricultural operations such as row crops, vineyards, or orchards. If these land conversions do not require grading, they would typically not require local approvals by the Permittees and therefore cannot be covered by the Plan.
- **Vineyard development that is not assessed by the County through a County permit process.** The creation of new vineyards or expansion of existing vineyards that does not go through a County permitting process (e.g., a grading and/or building permit) would not be subject to local approval and therefore cannot be covered by the Plan. The growth of private and commercial vineyards in Santa Clara County is expected to be low during the permit term, but impacts from vineyards may be significant and incompatible with the conservation strategy. Vineyard impacts include sediment runoff to streams and reductions in local groundwater.
- **Timber harvest operations.** In 2004, approximately 67,000 board feet of timber were harvested in Santa Clara County, down by 40% from 2003 (County of Santa Clara, Division of Agriculture 2005). Most of this harvest occurs on private lands in the Santa Cruz Mountains. Due to the potentially extensive impacts associated with timber harvesting, the lack of understanding about what future projects might be proposed, and the need for some sites to acquire State timber harvesting permits, timber harvesting will not be covered by the Plan.
- **Quarries and other mining other than expansion of Freeman Quarry.** Quarries and other mining were considered for inclusion in this Plan. At the time of Plan development, only one specific project was proposed, the Freeman Quarry expansion. Due to the potentially extensive impacts associated with quarries and mining and the lack of understanding about what future projects might be proposed, the mining of sand or other aggregate material, or the mining of precious metals or other minerals is not covered by this Plan other than for the Freeman Quarry expansion. This exclusion does not include gravel augmentation conducted to enhance fish habitat (described above under Three Creeks HCP conservation strategy) or mining activities associated with the borrow sites for seismic retrofits of dams as described in Section 2.3.3 *In-Stream Capital Projects*. Project proponents who propose any quarries or mining operations in the future in Santa Clara County are recommended to review the 2004 NMFS National Gravel Extraction Guidance for recommendations on how to conduct such activities in and near anadromous fish-bearing streams.
- **New and expanded landfills other than Kirby Canyon, Pacheco Pass Landfill expansions, and landfills occurring inside the planning limits of urban growth of the three cities.** Development of new or expanded landfills was considered for inclusion in this Plan. At the time of Plan development, no specific projects were proposed for inclusion beyond the Kirby Canyon and Pacheco Pass Landfill expansions. Due to the potentially extensive impacts associated with new or expanded landfills and a lack of

understanding about what future projects might be proposed, the development of new or expanded landfills is not covered by this Plan. This does not apply to the expansion of Z Best Composting facility, which is considered a recycling facility under County ordinance.

- **Mercury removal/remediation.** Mercury removal/remediation projects other than those described in Section 2.3.4 *In-Stream Operations and Maintenance* are not covered activities under this Plan. Mercury removal that occurs in the course of sediment removal or dredging projects is covered by the Plan (i.e., projects whose primary purpose is sediment removal, not mercury remediation).
- **Corps led projects.** Projects that are led by the Corps (i.e., the Corps has control over design, avoidance and minimization measures, and mitigation), including levee and flood protection projects, are not covered activities under this Plan. These projects will require a separate Section 7 consultation associated with the Clean Water Act Section 404 permit application process.
- **Pacheco Dam reconstruction and reservoir enlargement.** SCVWD may in the future enlarge Pacheco Reservoir by rebuilding Pacheco Dam or constructing a new dam on Pacheco Creek with substantially more storage. This is one option for SCVWD to respond to the increasing unpredictability and unreliability of water supply in the study area. The project would be located on Pacheco Creek, approximately 1.5 miles upstream of the existing North Fork Dam near the upstream end of Lake Pacheco. Detailed design of this project has not yet begun, nor would it begin for several years to decades. This project is not a covered activity in the Habitat Plan. However, the Plan describes a special major amendment procedure and conservation strategy for terrestrial covered species that could be used by SCVWD if and when this project is proposed. See Chapter 10, Section 10.3.3 *Major Amendments*, for the details of this special amendment process for this project.
- **Pesticide/herbicide application for the federal permit.** Pesticide and rodenticide use is not an activity permitted by USFWS and will not be covered under this Plan for the federal permits. All applicable injunctions stipulated during plan implementation (i.e., 2006 California red-legged frog Stipulated Injunction) will be adhered to until formal consultation between the EPA and USFWS regarding the effects of pesticides on listed species is concluded. This activity is covered under the state permit.
- **Installation and operation of groundwater wells.** The Local Partners do not have a clear regulatory authority over the location of groundwater wells nor water rights associated with wells. In addition, it is very difficult to assess the impacts associated with groundwater well operation. Therefore, except as described above for open space and stream flow management, installation and/or use of groundwater wells will not be a covered activity of this Plan.
- **Increased development due to incorporation of San Martin.** Development associated with the future incorporation of San Martin and subsequent changes to land use and zoning that would allow denser, or

urban, development was not evaluated under this Plan and is not a covered activity.

- **Dam removal and/or construction of new dams.** Dam removal and/or construction of new dams are not covered activities under this Plan.
- **Wind farm development.** Construction and operation of wind farms is not a covered activity under this Plan.
- **Water importation from outside the SCVWD service area.** Importing water from outside of the service area of the SCVWD (County boundary) is not covered under this Plan. The primary source of imported water outside of the County is the Delta, and effects to Delta species were not analyzed in this Plan. Effects associated with imported water from the Delta are currently being evaluated under a Section 7 consultation with the Bureau of Reclamation.
- **Emergency activities not defined as a Changed Circumstance in Chapter 10.** During the permit term, the Local Partners and those under their jurisdiction may need to respond to emergencies, as defined in Section 2.3.8, above. The Wildlife Agencies will not obstruct any emergency response decisions made by the Local Partners. Existing consultation regulations will apply to emergency activities (50 CFR 402.05).

**Table 2-1.** Proposed Land Use Categories and Associated General Plan Land Use Designations

Habitat Plan Category	County of Santa Clara	City of Gilroy	City of Morgan Hill	City of San José
Urban Development	Major Gas & Electric Utilities	Hillside Residential (0.5-4 DU <sup>a</sup> /acre)	Residential Estate (0-1 DU/acre)	Estate Residential (1.0 DU/acre)
	Major Public Facilities	Low Density Residential (3-7.25 DU/acre)	Single Family Low (1-3 DU/acre)	Very Low Density Residential (2 DU/acre)
	Roadside Services	Medium Density Residential (8-16 DU/acre)	Single Family Medium (3-6 DU/acre)	Low Density Residential (5 DU/acre)
	Transportation	High Density Residential (16-30 DU/acre)	Single Family High (5-10 DU/acre)	Medium Low Density Residential (8 DU/acre)
	Major Educational & Institutional Uses	Neighborhood District (6-12.5 DU/acre)	Multi Family Low (5-14 DU/acre)	Medium Density Residential (8-16 DU/acre)
		Neighborhood Commercial	Multi Family Medium (14-21 DU/acre)	Medium High Density Residential (12-25 DU/acre)
		Professional Office	Multi Family High (21-40 DU/acre)	High Density Residential (25-50 DU/acre)
		Shopping Center Commercial	Commercial	Transit Corridor Residential (20+ DU/acre)
		Highway Commercial	General Commercial	Transit/Employment Residential District: 55+ DU/acre
		Commercial Industrial	Non-Retail Commercial	Residential Support for the Core Area (25+ DU/acre)
		Downtown Specific Plan Districts	Mixed Use	Planned Community
		Campus Industrial	Industrial	Urban Reserve (future development)
		Limited Industrial	Office Industrial	Mixed Use Overlay
		General Industrial	Campus Industrial	Mixed Industrial Overlay
		Park/Public Facilities	Public Facilities	Neighborhood/ Community Commercial
			Rural County (usually 1 DU/5-20 acres) <sup>b</sup>	Regional Commercial
				General Commercial
				Core Area
				Combined Residential/Commercial Office
				Transit-Oriented Development Corridor
				Industrial Park
				Administrative Office/Research & Development

Table 2-1. Continued

Habitat Plan Category	County of Santa Clara	City of Gilroy	City of Morgan Hill	City of San José
				Research/Development Campus Industrial Light Industrial Heavy Industrial Combined Industrial/ Commercial Industrial Core Airport Approach Zone Public/Quasi-Public
Rural Residential	Rural Residential (1 DU/5-20 acres)	Rural Residential (maximum of 1 DU/2.5 acres) Hecker Pass Special Use District		Rural Residential (1 DU/5 acres) Urban Hillside (1 DU/5 acres)
Ranchland	Ranchlands (1 DU/20-160 acres) Hillsides (1 DU/20-160 acres)			Non-Urban Hillside (1 DU/20-160 acres)
Agriculture	Agriculture Large Scale Agriculture Medium Scale	Agricultural Commercial Agri-tourist Commercial Agri-tourist Commercial Overlay		Agriculture Coyote Greenbelt Overlay
Urban Parks and Open Space		Open Space (in part) Park/Recreation Facility	Open Space (in part)	Public Park/Open Space (in part) Private Open Space (in part) Private Recreation (in part) Floating Park overlay
Rural Parks and Open Space	Baylands Open Space Reserve Other Public Open Lands Regional Parks, Existing	Open Space (in part)	Open Space (in part)	Public Park/Open Space (in part) Private Open Space (in part) Private Recreation (in part)
Notes				
<sup>a</sup> DU = dwelling units				
<sup>b</sup> Morgan Hill anticipates that existing land use designations of Rural County, currently falling within the development density for the Rural Residential land use category, will, over the course of the permit term, become denser. Therefore Morgan Hill's Rural County land use designation is included in the Urban Development land use category for this Plan.				

**Table 2-2.** Significant Open Space or Parkland Areas within the Study Area<sup>a</sup>

Open Space or Parkland	Primary Ownership (acres)	Other Ownership	Total Acres	Total Acres in Study Area
(unnamed parcels)	United States Bureau of Land Management		1,025	989
Cañada de los Osos Ecological Area (formerly Stevenson Ranch)	California Department of Fish and Game		4,200	4,200
Almaden Quicksilver County Park	County of Santa Clara Parks and Recreation Department (3,943)	SCVWD owns 209 acres	4,152	4,138
Anderson Lake County Park	County of Santa Clara Parks and Recreation Department (1,773)	SCVWD owns 1,339 acres	3,144	3,144
Calero County Park	County of Santa Clara Parks and Recreation Department (2,603)	SCVWD owns 890 acres	4,455	4,442
Coyote Creek Parkway	County of Santa Clara Parks and Recreation Department (1,613)	SCVWD owns 81 acres	1,694	1,694
Coyote Lake-Harvey Bear Ranch County Park	County of Santa Clara Parks and Recreation Department (3,663)	SCVWD owns 932 acres	4,595	4,595
Ed R. Levin County Park	County of Santa Clara Parks and Recreation Department (1,541)		1,541	973
Joseph D. Grant County Park	County of Santa Clara Parks and Recreation Department (9,560)		9,560	9,560
Motorcycle County Park	County of Santa Clara Parks and Recreation Department (442)		442	442
Mount Madonna County Park	County of Santa Clara Parks and Recreation Department (3,677)		3,677	3,669
Santa Teresa County Park	County of Santa Clara Parks and Recreation Department (1,568)	SCVWD owns 9 acres	1,646	1,646
Uvas Canyon County Park	County of Santa Clara Parks and Recreation Department (1,133)		1,133	1,127
Palassou Ridge Open Space Preserve	Santa Clara County Open Space Authority		3,515	3,515
Rancho Cañada del Oro Open Space Preserve	Santa Clara County Open Space Authority		3,602	3,602

Table 2-2. Continued

Open Space or Parkland	Primary Ownership (acres)	Other Ownership	Total Acres	Total Acres in Study Area
Sierra Vista Open Space Preserve	Santa Clara County Open Space Authority		1,676	1,676
Mitigation site	Santa Clara Valley Transportation Authority		603	603
Alum Rock Park	City of San José		703	703
Kirby Landfill easement	City of San José		250	250
Coyote Ridge Ecological Preserve	Silicon Valley Land Conservancy		95	95
Tulare Hill Ecological Preserve	Silicon Valley Land Conservancy		116	116
Blue Oak Ranch Reserve	University of California Natural Reserve System		1,319	706
Romero Ranch	The Nature Conservancy		28,781	10,674
San Felipe Ranch (conservation easement)	Easement held by The Nature Conservancy		28,359	24,983
Silacci Ranch (conservation easement)	Easement held by The Nature Conservancy		1,388	1,388

Notes:

<sup>a</sup> Significant open space or parklands are large areas or highly biologically valuable that may support the Plan's conservation strategy.

**Table 2-3.** Examples of Open Space Types<sup>a</sup> in the Study Area

Type 1 Open Space	Type 2 Open Space	Type 3 Open Space	Type 4 Open Space
<ul style="list-style-type: none"> <li>• Properties under easement managed by The Nature Conservancy</li> <li>• Santa Clara Valley Open Space Authority properties under easement or other protections from change in land use</li> <li>• Designated biological mitigation sites under easement</li> <li>• Private property under conservation easement with the primary purpose of ecological protection</li> </ul>	<ul style="list-style-type: none"> <li>• Santa Clara Valley Water District watershed protection areas</li> <li>• Santa Clara Valley Open Space Authority properties without permanent protections or where protections are uncertain or pending</li> <li>• City of San Jose rural parks and open space</li> <li>• San Francisco Public Utilities Commission watershed lands</li> <li>• Bureau of Land Management properties</li> </ul>	<ul style="list-style-type: none"> <li>• Santa Clara County Parks and Recreation Department rural parks</li> <li>• Santa Clara County historic sites or recreation areas</li> <li>• Santa Clara County urban creek parks</li> </ul>	<ul style="list-style-type: none"> <li>• Private properties under agricultural easement (cropland)</li> <li>• Golf courses</li> <li>• Urban parks or open space owned by cities</li> </ul>

Notes:

<sup>a</sup> See Figure 2-3 and Chapter 2 for definitions of open space types.

**Table 2-4.** Dry and Wet Season Maximum and Minimum Covered Reservoir Dewatering Flows for SCVWD Reservoirs for the Purpose of Triggering Additional Wildlife Agency Approval Requirements

Reservoir	Allowable Daily Dewatering Flows (cfs) <sup>1</sup>			
<b>Dry Season</b> (May 1 to October 31, 184 days)	Minimum <sup>2</sup>	Average <sup>3</sup>	Maximum	Outlet Capacity (cfs)
Almaden <sup>4</sup>	1	5	10	190
Anderson <sup>5</sup>	3	50	50	100 (550)
Calero <sup>4</sup>	1	15	20	75
Coyote <sup>4</sup>	2	34	49	450
Guadalupe <sup>5</sup>	1	10	10	235
Chesbro	1	10	20	740
Uvas	1	32	39	165
<b>Wet Season</b> (November 1 to April 30, 181 days)	Minimum	Average <sup>3</sup>	Maximum <sup>7,8</sup>	Outlet Capacity (cfs)
Almaden <sup>4</sup>	1	59	190	190
Anderson <sup>5,6</sup>	5	467	550	100 (550)
Calero <sup>4</sup>	1	31	75	75
Coyote <sup>4</sup>	2	202	450	450
Guadalupe <sup>5</sup>	1	28	235	235
Chesbro	1	79	740	740
Uvas	2	165	165	165

Notes:

<sup>1</sup> Flows are based on one year dewatering program beginning May 1 with a dewatered reservoir by April 30. Average flows are those releases that can dewater the reservoir in the one year timeframe and are based on wet year conditions beginning with a full reservoir (Scenario 3).

<sup>2</sup> Minimum flows are provided for lower limit to indicate no stream dry-back.

<sup>3</sup> Average flow is based on the daily average flow over the entire period during which the reservoir is dewatered beginning with a full reservoir on May 1 and an inflow of 10% exceedance probability.

<sup>4</sup> Reservoirs with fish management objectives.

<sup>5</sup> Reservoirs with cold water and fish management objectives.

<sup>6</sup> Maximum winter flow releases could be made per the flood rule curves, per DSOD restriction, pulse flows, or when they mimic natural hydrology.

<sup>7</sup> Anderson Dam flows between 100 cfs and 550 cfs can be made by delivering water to treatment plants in addition to releasing water to the stream. Pumping would be required.

<sup>8</sup> Pulse flows implemented for the benefit of anadromous fish species (see Section 2.3.4) may be greater than the flows anticipated for draining of a reservoir as part of a dewatering event. These higher flows are also covered by this Plan. Implementation of pulse flows may require additional regulatory approval (i.e., NMFS and CDFG for federal- and state-listed fish species).

**Table 2-5.** Existing Interim Storage Restrictions for SCVWD Dams

Dam	DSOD Storage Restrictions as of October 31, 2011 <sup>1</sup>
Almaden Dam	20%
Anderson Dam	31%
Chesbro Dam	none
Coyote Dam	48%
Calero Dam	54%
Guadalupe Dam	35%
Uvas Dam	none
Vasona Dam	none

<sup>1</sup> Percentages reflect reduction in current reservoir capacity, not new operating capacity.

**Table 2-6.** Specific Transportation Projects that are Covered by the Plan

Project	Approximate Length in Permit Area (miles)	Approximate Width of New Construction (feet)	Lead Agency
<b>County Roadway Projects (includes extensions, new connections, realignments, and widenings)</b>			
<i>Ferguson/New North-South Corridor</i>			
Ferguson Road widening (SR 152E to Leavesley Road)	1.8	24.0	Santa Clara County
New Avenue widening (Leavesley Road to Buena Vista Avenue)	1.4	24.0	Santa Clara County
New Avenue widening (Buena Vista to San Martin Avenue)	3.6	20.0	Santa Clara County
New Avenue realignment at approach to San Martin Avenue	0.2	46.0	Santa Clara County
<i>Marcella/Center/Hill/Peet North-South Corridor</i>			
Marcella Avenue widening and removal of short zig-zag in road (Leavesley Road to Buena Vista Avenue)	1.6	24.0	Santa Clara County
Center Avenue extension/new connection (Omar Avenue to Buena Vista Avenue; requires a new stream crossing)	0.2	92.0	Santa Clara County
Center Avenue widening (Omar Street to just south of Maple Avenue)	5.1	24.0	Santa Clara County
Center Avenue and Hill Road new connection at Maple Avenue	0.2	92.0	Santa Clara County
Hill Road widening (Dunne Avenue to E. Main Avenue) – along border of Morgan Hill planning limit of urban growth	1.2	24.0	Santa Clara County
Hill Road extension/new connection (East Main Avenue to Half Road and Peet Road new connection to Half Road – along border and inside of Morgan Hill planning limit of urban growth)	0.6	92.0	Santa Clara County
<i>Monterey Road North-South Corridor</i>			
Monterey Road widening (Watsonville Road to Masten Avenue/Fitzgerald Avenue)	4.4	24.0	Santa Clara County
<i>Santa Teresa/Hale Corridor (includes Sunnyside and DeWitt)</i>			
Santa Teresa Boulevard widening (Castro Valley Road to 10 <sup>th</sup> Street/Thomas Road) – along border of Gilroy planning limit of urban growth	1.3	24.0	Santa Clara County
Santa Teresa Boulevard widening (Day Road/Buena Vista Avenue to Watsonville Road)	5.0	24.0	Santa Clara County
DeWitt Avenue new connection to W. Edmundson Avenue and Sunnyside Avenue intersection	0.4	92.0	Santa Clara County

Table 2-6. Continued

Project	Approximate Length in Permit Area (miles)	Approximate Width of New Construction (feet)	Lead Agency
DeWitt Avenue widening and removal of small "S" curve (North of W. Edmundson Avenue to Spring Avenue)	0.7	24.0	Santa Clara County
Hale Avenue widening (Morgan Hill planning limit of urban growth border [0.8 miles south of Tilton] to Palm Avenue)	3.3	24.0	Santa Clara County
<i>Uvas/McKean/Almaden North-South Corridor</i>			
Uvas widening – to vary between adding center turn lane and widening shoulders (Watsonville Avenue to McKean Road/Bailey Avenue)	9.8	8.0 to 20.0	Santa Clara County
McKean Road widening (Bailey Avenue to Almaden Road) includes curve realignment at Calero Reservoir Park	4.2	24.0	Santa Clara County
McKean Road extension/new connection to Almaden Expressway – along border and inside of San José planning limit of urban growth	0.2	92.0	Santa Clara County
<i>East-West Corridors</i>			
Leavesley Road Widening (Ferguson Road to Marcella Avenue) – along border of Gilroy planning limit of urban growth	1.3	24.0	Santa Clara County
Masten Avenue widening (U.S. 101 to Monterey Road) – along border of Gilroy planning limit of urban growth	0.7	24.0	Santa Clara County
Fitzgerald Avenue widening (Monterey Road to Santa Teresa Boulevard) – along border of Gilroy planning limit of urban growth	0.7	24.0	Santa Clara County
Fitzgerald Avenue approach to Monterey Road, realignment 30 feet north to create a perpendicular intersection – along border of Gilroy planning limit of urban growth	<0.1	30.0	Santa Clara County
San Martin Widening (U.S. 101 to Santa Teresa Boulevard)	1.4	24.0	Santa Clara County
<b>Interchange Projects</b>			
U.S. 101 at Buena Vista Interchange	0.4/0.3	700	Santa Clara Valley Transportation Authority
U.S. 101 at Coyote Valley Parkway Interchange	0.2/0.4	150	Santa Clara Valley Transportation Authority
U.S. 101 at East Middle Interchange	0.3/0.3	900	Santa Clara Valley Transportation Authority
SR 152 and SR 156 Interchange	0.3/1.0	100	Santa Clara Valley Transportation Authority

Project	Approximate Length in Permit Area (miles)	Approximate Width of New Construction (feet)	Lead Agency
<b>Highway Projects</b>			
U.S. 101 Improvement Project (Monterey Road to SR 129; VTA ID H101-22) includes extending Santa Teresa Boulevard from Castro Valley Road to U.S. 101 (requires a new stream crossing) <sup>1</sup>	12.9	100	Santa Clara Valley Transportation Authority
U.S. 101 widening between Cochrane Rd. and Monterey Hwy (VTA ID H101-23)	5.1	32	Santa Clara Valley Transportation Authority
S.R. 237 HOV/HOT lane (full length inside the study area) – includes converting the existing median to express lanes	2.3	32	Santa Clara Valley Transportation Authority
S.R. 85 HOV/HOT lane (full length inside the study area) – includes converting the existing median to express lanes	11.6	32	Santa Clara Valley Transportation Authority
U.S. 101 HOV/HOT lane (western study area boundary to Cochrane Road) – includes converting the existing median to express lanes <sup>2</sup>	26.7	32	Santa Clara Valley Transportation Authority
U.S. 101 HOV/HOT lane (Cochrane Road to Masten Avenue; VTA ID H6) – includes converting the existing median to express lanes	7.5	32	Santa Clara Valley Transportation Authority
U.S. 101 HOV/HOT lane (Masten Avenue to 10 <sup>th</sup> Street; VTA ID H7) – includes converting the existing median to express lanes	4.2	32	Santa Clara Valley Transportation Authority
U.S. 101 HOV/HOT lane (10 <sup>th</sup> Street to SR 25; VTA ID H8) – includes converting the existing median to express lanes	3.0	32	Santa Clara Valley Transportation Authority
<b>Mass Transit Projects</b>			
Caltrain South County—double tracking from San José to Gilroy (VTA ID T6)	10.4	14	Santa Clara Valley Transportation Authority

<sup>1</sup> Only the portion of this project in Santa Clara County is covered by the Plan. Mitigation for the portion of the project in San Benito County could be accomplished through the Habitat Plan, consistent with the portion of the project in Santa Clara County. Mitigation required for the San Benito County portion of the project would be additive to the requirements of the Habitat Plan for the Santa Clara County portion.

<sup>2</sup> Only the portion of this project in the study area is covered by the Plan. Mitigation for the portion of the project outside of the study area could be accomplished through the Habitat Plan, consistent with the portion of the project in the study area. Mitigation required for the portion outside of the study area would be additive to the requirements of the Habitat Plan for the study area portion.

**Santa Clara Valley Habitat Plan Land Use Categories**

**Figure 2-3**  
**Open Space Categories in the Santa Clara Valley Habitat Plan Study Area**

## Criteria

### Type 1 Open Space

- 1) The primary management goal is related to ecological protection.
- 2) That protection is irrevocable through local, state or federal authority and there are legal assurances such as wilderness status or a conservation easement that the primary land use will never change.

### Type 2 Open Space

- 1) The primary management goal is related to ecological protection.
- 2) The land is not subject to irrevocable protection from a change in primary land use or protections are uncertain or political in nature.

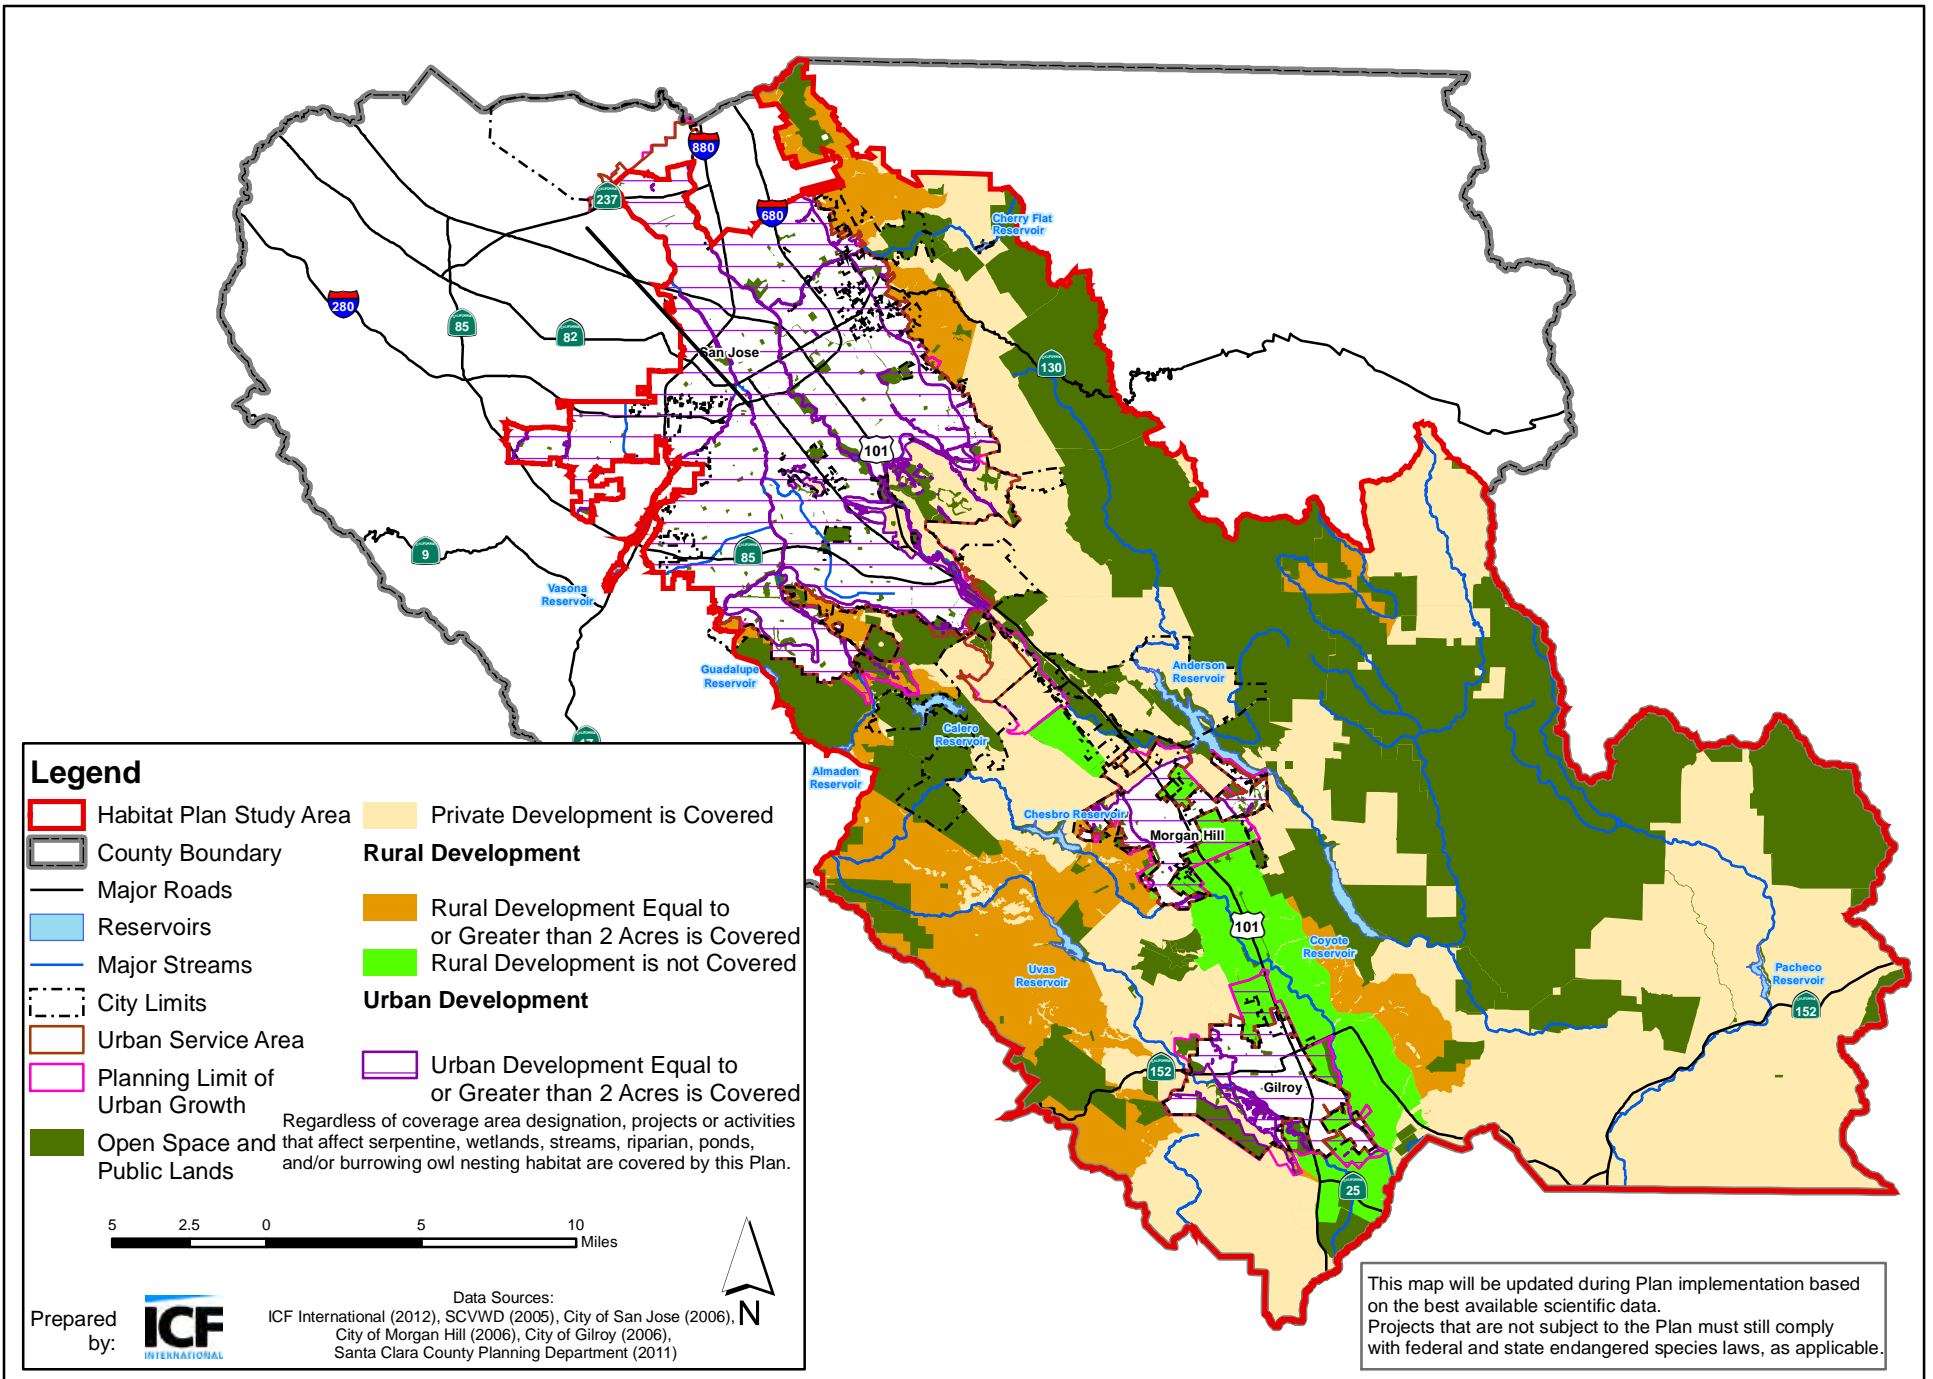

### Type 3 Open Space

- 1) Ecological protection is not a primary management goal, but land is managed as open space and has a consistent and measurable ecological value (allows multiple species to complete some portion of their life cycle [e.g. reproduction, growth, foraging] or provides critical refuge and movement opportunities [e.g. migration corridor]).

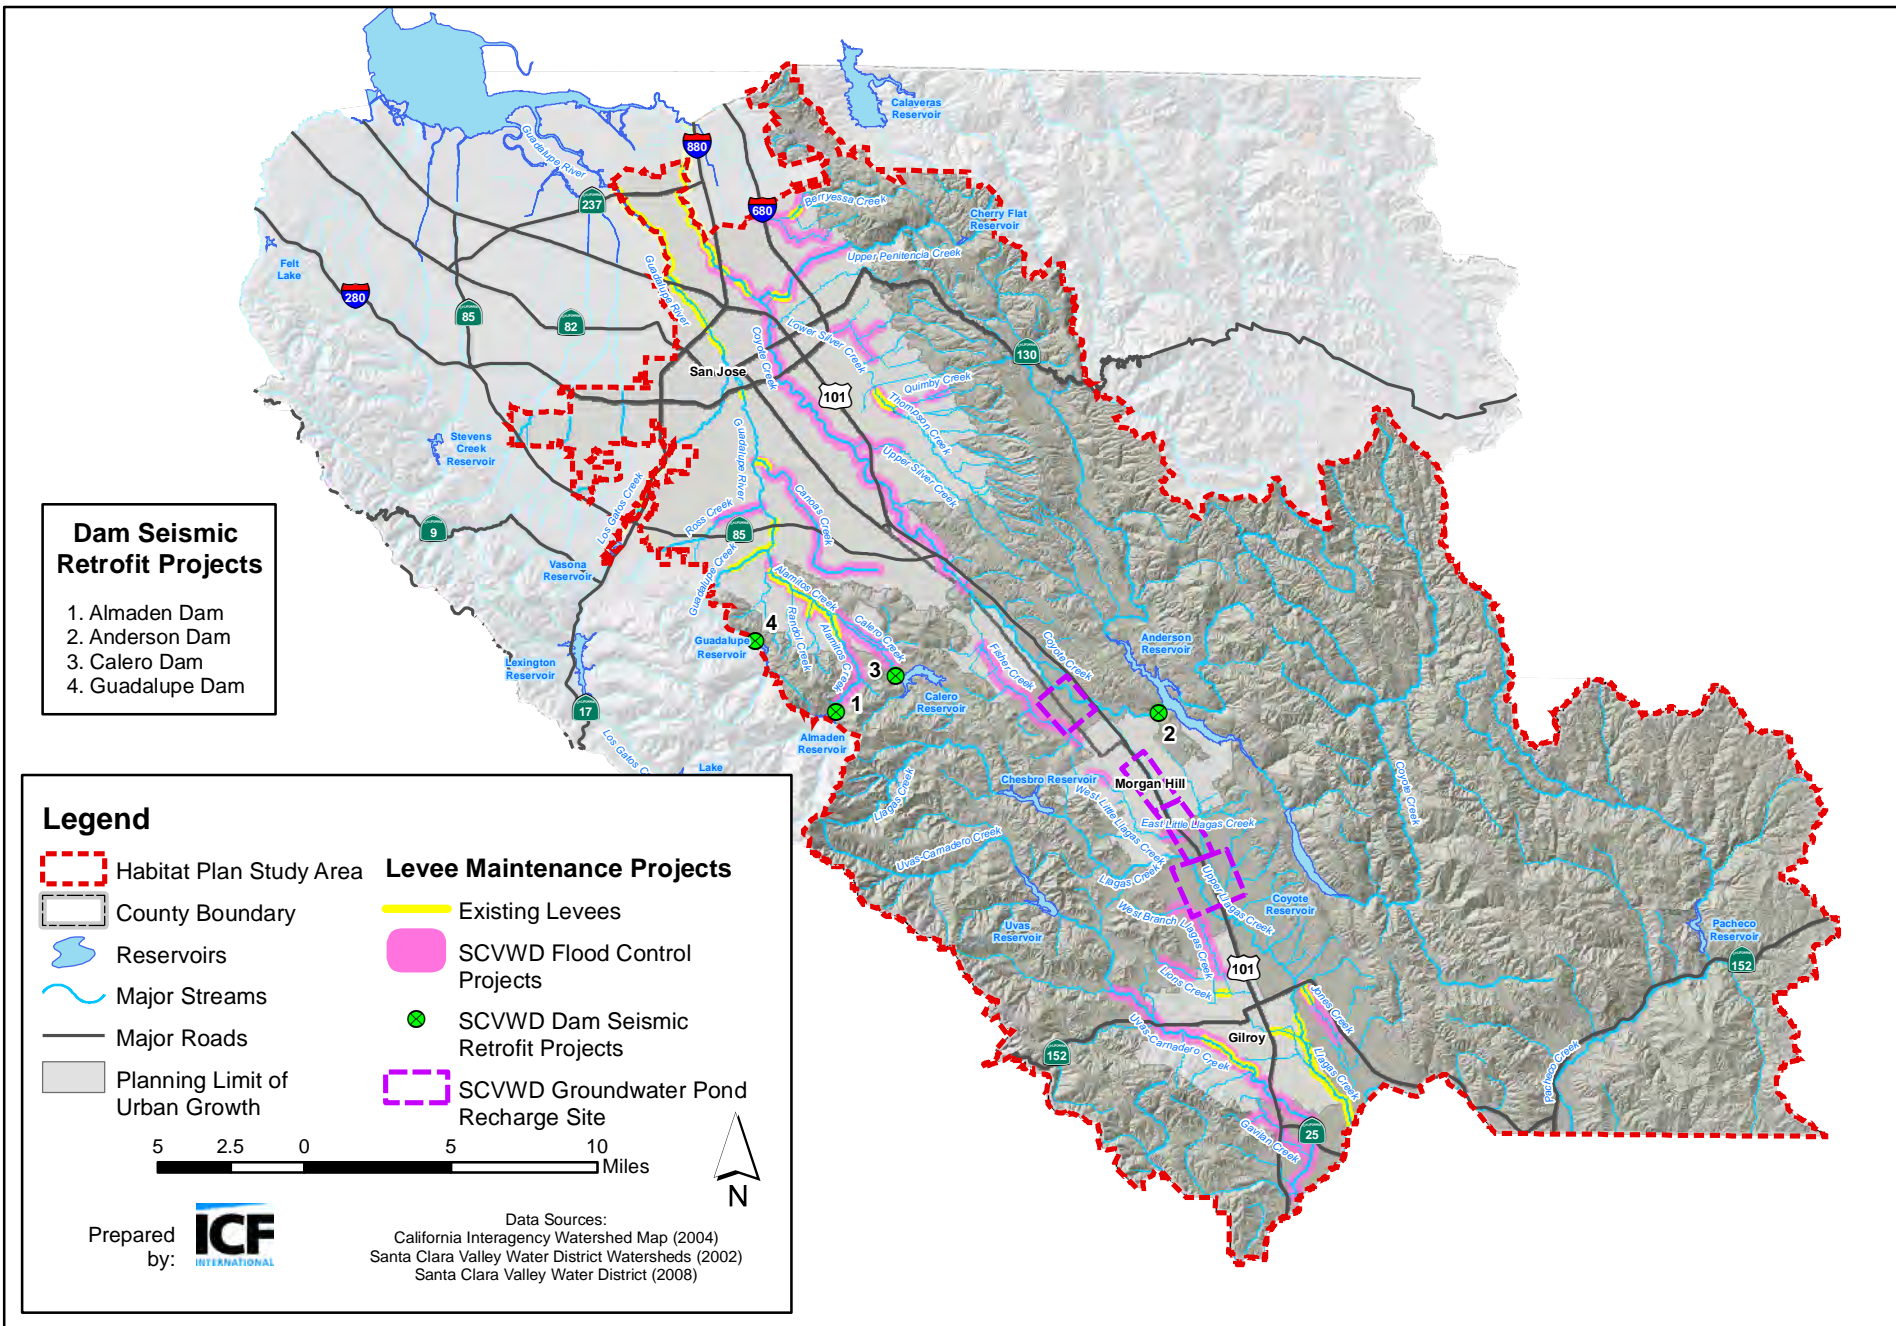

### Type 4 Open Space

- 1) The land is undeveloped but current management goals do not promote any consistent or measurable ecological value.

## Chapter 3

# Physical and Biological Resources

### 3.1 Introduction

This chapter presents an overview of the physical and biological setting of the Plan study area. It describes the baseline physical and biological conditions upon which the impact analyses (Chapter 4 *Impact Assessment and Level of Take*) and conservation strategy (Chapter 5 *Conservation Strategy*) are based. The chapter also describes how existing data were used and new data were collected to create the baseline inventory. The physical setting of the study area is described in the context of the following subject areas.

- Location.
- Topography.
- Geology and soils.
- Climate and hydrology.
- Data sources and methods.

The biological setting of the study area is described in terms of the following subject areas.

- Land cover types.
- Associated wildlife and plants.
- Ecosystem function.
- Natural disturbances.
- Threats to each natural community.

The ecology and distribution of covered species are described along with species-habitat models that define the suitable or potential habitat for most covered species (**Appendix D**).

This chapter also explains how the land cover types, habitats, disturbances, ecosystem services, and current management of the lands are inter-related to provide a context for the management of the Reserve System described in Chapter 5.

## 3.2 Physical Setting

This section describes the physical setting of the study area including location, topography, geology and soils, hydrology, climate and watersheds.

### 3.2.1 Location

The Plan study area (519,506 acres) is located in Santa Clara County in the central California Coast Range<sup>1</sup>. The primary valley in the study area is the Santa Clara Valley, which stretches from San Francisco Bay to San Benito County. The Santa Clara Valley is bounded on the east by the Diablo Range, on the west by the Santa Cruz Mountains, and on the north by the San Francisco Bay shoreline. The study area excludes tidally influenced portions of the Baylands (**Figure 1-2**). For a description of the political, ecologic, and hydrologic factors used to define the study area, see Chapter 1 *Introduction*.

### 3.2.2 Topography

#### Overview

The Santa Clara Valley is the southerly, on-land portion of a regional topographic depression that includes San Francisco Bay as well as the Petaluma, Sonoma, and Napa Valleys to the north (Norris and Webb 1990). Roughly hourglass in shape, the Santa Clara Valley is approximately 11 miles wide at the southern end of San Francisco Bay, narrowing to a minimum of about 2.5 miles north of Morgan Hill.<sup>2</sup> The Santa Clara Valley extends south to the county line, where it widens to approximately seven miles and merges with the Bolsa and Hollister Valleys in San Benito County. The valley floor is nearly flat along the Bay, with gentle undulations and local, low hills to the south. Valley floor elevations increase from sea level in the north to approximately 350 feet above mean sea level (msl) at the valley's narrowest point north of Morgan Hill (**Figure 3-1**). This low "saddle" in the valley represents the watershed divide between the Coyote Valley Watershed in which streams flow north to San Francisco Bay, and the watersheds to the south in which streams flow south to the Pajaro River and ultimately to Monterey Bay (see *Watersheds* below for watershed descriptions).

On the west side of the valley, the Santa Cruz Mountains rise to a maximum elevation of almost 4,000 feet msl. Typical of the Coast Ranges, the range trends

<sup>1</sup> State Parks lands (Henry W. Coe State Park and Pacheco State Park) fall within the study area; however they are excluded from the permit area. As such, all of the land cover-based analyses in the Plan are based on the study area less State Parks lands unless otherwise noted. The size of the study area less State Parks lands is 460,205 acres.

<sup>2</sup> The narrowest portion of Santa Clara Valley is also referred to as Coyote Valley, and Coyote Valley is sometimes considered a separate geomorphic entity from the Santa Clara Valley. This Plan considers Coyote Valley a part of the greater Santa Clara Valley.

northwesterly and is characterized by steep, rugged slopes and abrupt, deeply incised drainages. The steepest interior portions of the range are bounded along the valley floor by more gently sloping foothills largely representing dissected alluvial fan geomorphology.

On the east side of the valley, the Diablo Range forms a similarly rugged barrier, flanked by more gently sloping but strongly dissected alluvial foothills. Like the Santa Cruz Mountains, the Diablo Range is a long, northwest-trending uplift characterized by extremely rugged topography and heights in excess of 1,000 feet. The highest peak in the range is Mt. Hamilton (4,213 feet msl), in Santa Clara County but immediately east of the study area. Other important peaks in the study area include, from north to south, Monument Peak (2,594 feet msl) at the County line, Mt. Madonna (1,897 feet msl), and Pacheco Peak (2,770 feet msl). Elevations in the study area are generally greatest within the Diablo Range, particularly in the southeast portion of the study area. The highest point in the study area is 3,777 feet msl within Henry W. Coe State Park (**Figure 3-1**). The highest point in the Santa Cruz Mountains within the study area is 3,644 feet msl (**Figure 3-1**).

## Slope and Aspect

The rugged topography of the study area creates highly variable slopes and aspects. Slope may provide some insight to the type of land cover that could be present. Moreover, it is often incorporated into zoning restrictions as a function of a parcel's buildability. **Figure 3-2** shows the range and location of slope in the study area. Aspect is expressed as an azimuth (compass bearing) representing the direction normal to the plane that approximates the slope. South and southwest-facing slopes tend to receive the greatest amount and intensity of solar radiation in the study area, which can greatly influence vegetation and species occurrence. North and northeast-facing slopes are often the coolest aspects, all else being equal. Note the predominance of generally northeast- and southwest-facing slopes, consistent with the overall northwesterly trend of the ranges (**Figure 3-2**).

### 3.2.3 Geology

The geology and fault zones of the study area have an important influence on the distribution of landforms and soil types, which in turn influence vegetation and plant species distribution and abundance. In some cases, geology and soils also greatly influence wildlife species distribution. For example, many invertebrates are closely associated with particular plant species or vegetation types that are restricted to particular soil types and geologic substrates. On a regional scale, geologic activity has also greatly influenced the pattern of stream formation and the structure and function of local watersheds<sup>3</sup>.

<sup>3</sup> Faults can also be an important source of groundwater for stream flow, particularly in droughts. In severe droughts (e.g., 1976–1977), stream reaches in or near faults were often the only local perennial stream habitat, serving as

## Faulting

Topography in the study area largely reflects active tectonics associated with the fault system of the San Andreas plate boundary.

The Santa Cruz Mountains are being uplifted along a system of faults related to the San Andreas plate-boundary system (Kennedy and Hitchcock 2004). The San Andreas fault zone itself, the primary fault within the system, lies northwest along the east flank of the uplift (e.g., Wagner et al. 1991; Hart and Bryant 1997).

The western front of the Diablo Range is defined by the Hayward and Calaveras faults, both of which are active faults of the San Andreas system (Anderson et al. 1982; Wagner et al. 1991; Hart and Bryant 1997). The eastern range front bounding the San Joaquin Valley (i.e., the eastern edge of the Diablo Range) is also defined by faulting.

## Geologic Units

### Santa Cruz Mountains

The Santa Cruz Mountains uplift exposes a wide range of bedrock units in a complexly deformed series of fault slivers. These include a variety of units assigned to the Jura-Cretaceous Franciscan Complex: sandstone, greenstone, serpentinized ultramafic rocks, and small bodies of limestone. Volcanic rocks of Eocene and Miocene age and volcanic strata also of Miocene age are exposed locally. The low foothills along the eastern range front consist of Pleistocene alluvium recording uplift of the range (e.g., Wagner et al. 1991).

Ultramafic rocks are characterized by the occurrence of some form of ferromagnesian silicate mineral and are common throughout the world as local outcrops or large, regional formations. In the Coast Range of California, most ultramafic rocks are of the serpentinite variety. The prevailing view of the origin of Franciscan-associated serpentinites is that they are altered masses derived from the upper mantle and transferred tectonically to the earth's surface (Norris and Webb 1990). Therefore, serpentinite is often associated with southeast-to-northwest trending fault zones, as is the case in the study area. Serpentinite, and the serpentine soils derived from them, are distributed widely in California in the Coast Range from Santa Barbara County to the Oregon border and in the western Sierra Nevada foothills from Tulare to Plumas Counties (Kruckeberg 1984). Serpentine soils are particularly relevant to the ecology of the study area because they support unique species assemblages (see *Serpentine Soils* discussion below).

---

critical refuges for fish. Examples included: Upper Silver Creek (Silver Creek Fault), Arroyo Aguague (Calaveras Fault) as a source of flow for Upper Penitencia Creek, Coyote Creek between Coyote and Anderson reservoir (Calaveras Fault) and also downstream of Gilroy Hot Springs (Madrone Fault), San Felipe Creek (Calaveras Fault), Bodfish Creek (Sargent Fault), and Tar Creek (Sargent Fault) (J. Smith pers. comm.).

## Diablo Range

The central portion of the Diablo Range consists of *mélange*—locally including serpentinitic bodies—and metasandstone of the Jura-Cretaceous Franciscan Complex. Outcrops of mafic and ultramafic units (i.e., serpentinite) belonging to the Jurassic Coast Range Ophiolite are also locally present, and are particularly well developed along the active Ortigalita fault in the vicinity of Del Puerto Canyon (Wagner et al. 1991; Evarts et al. 1999).

The western Diablo range front is flanked by complexly faulted exposures of sedimentary strata of Cretaceous through Miocene age. These include deep marine strata assigned to the Great Valley Group, shallow marine strata of the Miocene San Pablo Group, and terrestrial strata of the Miocene Contra Costa Group (Wagner et al. 1991). Quaternary alluvial strata accumulated on essentially modern topography buttress against the range front, and both active (Holocene) alluvium and older Quaternary terrace deposits are present in the larger stream valleys (Wagner et al. 1991).

## Valley Floor

The Santa Clara Valley is filled by as much as 1,950 feet of primarily continental (alluvial) sediment largely accumulated within the last 780,000 years. These deposits are essentially flat-lying (Wentworth et al. 2005).

### 3.2.4 Soils

Because of the geologic, climatic, and topographic diversity of the Santa Clara Valley and neighboring uplands, the study area's soils are also very diverse, and a large number of individual soil units have been mapped in the study area. These have been organized into 20 soil associations consisting of soil units of the same texture and composition. Following is a general overview of soil characteristics in the Santa Clara Valley and adjacent areas, by geographic position (U.S. Soil Conservation Service 1968, except as noted). **Figure 3-3** shows generalized soil type distribution in the study area.

- **Lowland areas influenced by tidal waters.** These typically fine-textured, saline, clay-rich soils are restricted to the north-central portion of the study area, along the Bay margin and as far south as parts of the Mountain View-Sunnyvale area. Plant associations supported by these soils may be limited by soil salinity and/or moisture content.
- **Level, low-lying valley areas.** Soils of the Santa Clara Valley flatlands are typically very deep, fine- to medium-textured, and poorly to somewhat poorly drained under natural conditions. Plant associations on these soils may be limited by soil texture and/or moisture content.
- **Major valley drainageways and lower alluvial fan surfaces.** Most soils formed on the flat alluvial plains along major valley drainages and on gently

to moderately sloping surfaces on the lower portions of alluvial fans are medium-textured, although some are gravelly. They range from moderately well drained to somewhat excessively drained under natural conditions. These soils are considered very good for cultivation.

- **Older alluvial fans and terraces in valley-margin and foothills.** Soils of the study area's older alluvial fans and terraces are texturally diverse. They are typically moderately drained to well drained but are underlain by subsoils that contain abundant clay and thus drain slowly. Plant associations on these soils may be limited by low fertility and/or low moisture content.
- **Upland soils.** Soils of the study area's mountainous uplands are typically shallow and well drained and have developed on site from local bedrock.

## Serpentine Soils

Of particular importance from a conservation perspective are the study area's serpentine soils, which are derived from the serpentinite ultramafic rocks of the region. Serpentine soils are typically very shallow, nutrient-poor (i.e., low levels of nitrogen, potassium, phosphorous, and molybdenum essential for normal plant growth), high in magnesium, and may contain elevated levels of the heavy metals chromium and nickel that are toxic to many plant species (Kruckeberg 1954, 1984). Water availability in serpentine soils may also be limited (Davis et al. 1997). As a result, serpentine soils support limited and highly specialized floras and vegetation associations that often include a high number of endemic (i.e., largely or entirely restricted to serpentine soils) and special-status species (Kruckeberg 1984; Safford et al. 2005).

The occurrence of serpentine soils in Santa Clara County is best predicted by a combination of soil and geology maps. As shown in **Figure 3-4**, the study area supports an estimated 13,180 acres of serpentine soils, 9,194 acres of serpentine bedrock, and 12,636 acres where serpentine soil and bedrock overlap (Brabb and Dibblee 1974; Dibblee 1973, 1977)<sup>4</sup>. As inferred from serpentine soil and geology maps, we estimate a total of 35,010 acres of serpentine soils in the study area. By far the largest occurrence of serpentine in the study area is along the low ridge immediately east of U.S. 101 known as the "Kirby Hills" or "Coyote Ridge" between the Silver Creek Hills and Anderson Reservoir (this document uses the name Coyote Ridge for this feature). Other important outcrops of serpentine soils in the study area occur in or on the following areas:

- the Santa Teresa Hills,
- Communications Hill,
- Tulare Hill,
- the foothills of the Santa Cruz Mountains near Chesbro and Calero Reservoirs,

<sup>4</sup> For the purposes of this Plan, serpentine soils are assumed to occur where serpentine soils and serpentine bedrock are mapped. Each map layer alone is insufficient to fully represent field conditions.

- the foothills adjacent to and west of Anderson Reservoir, and
- the foothills adjacent to and west of Coyote Creek upstream of Anderson Reservoir and Coyote Reservoir.

Serpentine plants occur in small patches outside mapped serpentine soils and geology, possibly due to serpentine alluvial material washing downstream (J. Hillman pers. comm.).

## 3.2.5 Climate and Hydrology

### Climate

Santa Clara County has a Mediterranean climate, characterized by extended periods of precipitation during the winter months and virtually no precipitation from spring through autumn. The wet season generally extends from November through April, while rainfall from May through October tends to be minimal. Annual average rainfall varies significantly due to topography and related orographic and rain shadow effects. Increased elevation on coastal oriented slopes (typically west/southwest facing) results in increased precipitation while descending the lee-side interior facing (typically east/northeast facing) results in decreased precipitation. A rainfall transect across the county illustrates this condition. For example, portions of Santa Clara County in the Santa Cruz Mountains receive 40 to 60 inches per year. Moving east, down the lee side of the Santa Cruz range into the rain shadow of the central Santa Clara Valley, precipitation falls an average of 13 to 14 inches in the vicinity of downtown San José (Santa Clara Basin Watershed Management Initiative 2003); see **Figure 3-5**. Similarly, moving further east and ascending the west facing slopes of the Diablo Range, precipitation increases with elevation to 20–30 inches per year. Further east into the interior valleys and ridgelines of the Diablo Range, precipitation amounts similarly fluctuate with elevation and aspect. In addition to orographic/rain shadow effects, site-specific conditions of elevation and aspect will influence local microclimates and water balance conditions. For example, canyon areas of north facing hillslopes and streams that experience less sunlight and less day-length will have less evapotranspiration, greater ambient soil moisture, and generally more moderate and cooler temperatures due to higher moisture content and greater shade.

The wind patterns in the Santa Clara Valley are influenced greatly by the terrain, resulting in a prevailing flow roughly parallel to the Valley's northwest-southeast axis. A north-northwesterly sea breeze often extends up the Valley during the afternoon and early evening and a light south-southeasterly drainage flow often occurs during the late evening and early morning. In summer a convergence zone is sometimes observed in the southern end of the Santa Clara Valley between Gilroy and Morgan Hill, when air flowing from the Monterey Bay through the Pajaro Gap gets channeled northward into the south end of the Santa Clara Valley and meets with the prevailing north-northwesterlies. Wind speeds are greatest in the spring and summer, and least in the fall and winter. Nighttime

and early morning hours have light winds and are frequently calm year round, while summer afternoon and evenings can be breezy. Strong winds are rare, coming only with occasional winter storms.

The average annual rainfall in San José for the period of record of July 1, 1948 to December 31, 2005 was 14.66 inches (Western Regional Climate Center 2006). Average rainfall figures can be somewhat misleading because, in addition to seasonal variation, droughts in California are not uncommon. For example, annual rainfall in San José between 1948 and 2005 ranged from 6.12 inches in 1953 to 32.57 inches in 1983 (Western Regional Climate Center 2006). Snow may occur in the mountains where the headwaters for the watersheds are located but melts quickly and does not provide flow from snowmelt in the late spring to early summer as occurs in the Sierra Nevada Mountains.

The Mediterranean climate also produces fairly mild air temperatures in the valley floor that rarely drop far below freezing. North of San José, the average summer temperatures are rarely higher than 90°F. South of San José both summer and winter extremes are somewhat greater (Santa Clara Basin Watershed Management Initiative 2003).

## Watershed Hydrology

The major watersheds within the northern portion of the Plan study area are those of the Coyote Creek and Guadalupe River. Portions of the upper Pajaro River Watershed occur in southern Santa Clara County and the study area (see **Figure 3-6**)<sup>5</sup>. Other major drainages that pass through Santa Clara Valley include the Los Gatos Creek, San Tomas Aquino Creek, Saratoga Creek, Calabazas Creek, Stevens Creek and Permanente Creek, all of which originate in the Santa Cruz Mountains. The lower portion of the Guadalupe River watershed is within the study area (**Figure 3-6**). Very small portions of the Calabazas Creek and San Tomas watersheds within San José are also part of the study area (**Figure 3-6**).

While rainfall is the primary source of surface flows in the County, high groundwater tables contribute to the flows of some local streams. Springs are a clear expression of groundwater intercepting the surface. In some areas, springs are an important contributor to perennial flows in local streams. There are 92 springs in the study area mapped by USGS; of these, seven occur on serpentine soils (**Figure 3-6**) and provide important habitat for Mt. Hamilton thistle, which is found primarily in serpentine seeps.

---

<sup>5</sup> The Pajaro Watershed in the study area includes the following watershed basins: Pacheco (in part), South Santa Clara Valley (in part), Llagas, Uvas, Pescadero (in part).

## Coyote Creek Watershed

The Coyote Creek Watershed is the largest watershed in Santa Clara County (206,000 acres, or approximately 40% of the study area) and is entirely contained within the County and the study area except for the outflow to the Bay. The headwaters originate on the east side of Santa Clara County in the Diablo Range. The watershed is bounded by Coyote Creek to the west and the Diablo Range to the east. Coyote Creek is the longest creek in the County at approximately 63 miles. It originates in the Diablo Range at approximately 3,000 feet and flows southward then northward towards South San Francisco Bay (Santa Clara Valley Water District 2002a). Between its headwaters and Anderson Dam, Coyote Creek and its tributaries flow through mostly steep canyons or narrow valleys. Downstream of Anderson Dam, Coyote Creek flows through the flat Santa Clara Valley on a historically wide alluvial plain.

Coyote Creek originates in the Diablo Range and enters Coyote Valley at its topographic divide with the Llagas Basin to the south. Coyote Creek flows northwesterly through Coyote Valley and Santa Clara Valley before entering San Francisco Bay at Alviso. The major tributaries entering Coyote Creek include Fisher Creek, Upper Silver Creek, Lower Silver Creek, and Upper Penitencia Creek (Santa Clara Valley Water District 2002a). Flow in Coyote Creek below Anderson Dam is perennial, and in the summer is sustained with seepage and releases from Anderson Dam, groundwater, and urban runoff (Santa Clara Valley Water District 2002a). The creek also tends to be dry in dry years on the valley floor between Hellyer Park and Capitol Expressway (J. Smith pers. comm. 2009; J. Abel pers. comm. 2010). Coyote Creek above Anderson and Coyote Reservoirs is intermittent in several reaches. Many of the creeks draining into Coyote Creek are perennial, but the smaller tributaries on the eastern side of the watershed are dry during the summer and fall (Santa Clara Valley Water District 2002a).

Upper Penitencia Creek is kept artificially perennial through releases from the South Bay Aqueduct and the City of San José's Cherry Flat Reservoir. Arroyo Aguague, a tributary to Upper Penitencia Creek in Alum Rock Park, provides surface flow to the creek even if there are no releases from Cherry Flat Reservoir (J. Smith pers. comm. 2009). Much like the Coyote Creek flow pattern, the perennial flow observed is the result of interim operations applied since the onset of the FAHCE proceedings. Under traditional operations, stream flow terminates at the Maybury diversion. Under interim operations a bypass flow is applied to maintain a hydraulic connection with the lower end of the stream and Coyote Creek. Despite augmented flow, recent summer droughts has resulted dry backs has occurred at Cherry Flat and Arroyo Aguague, upstream of the flow augment put-in point.

Coyote Valley is an extension of the Santa Clara ground-water basin and is commonly referred to as the Coyote Valley ground-water subbasin. The Coyote Narrows divides the Coyote Valley ground-water subbasin from the Santa Clara Valley ground-water basin. Characteristics of the basin and subbasin differ. Groundwater generally moves in a northwesterly direction or down the valley. The groundwater level in Coyote Valley is typically shallow or within 50 feet

below the surface. Groundwater recharge is predominately from percolation of flow in Coyote Creek in the first 5 to 10 miles downstream of Anderson Dam. Coyote Creek is quite responsive to winter rains and subsequent stormwater runoff. Further downstream, subsurface flow is forced to the surface as the valley becomes confined at Coyote Narrows and returns to the shallow subsurface as it enters the Santa Clara groundwater basin. At the divide between the Coyote and Llagas watersheds there is some movement of groundwater from the Coyote watershed to the Llagas watershed.

In the Coyote Watershed, the SCVWD operates two reservoirs—Anderson and Coyote—that regulate flow into Coyote Creek. Anderson Reservoir is the largest reservoir in Santa Clara County, with a capacity of 90,373 acre-feet. The Coyote Reservoir has a capacity of 23,244 acre-feet. The small (<500 acre-feet) Cherry Flat Reservoir, operated by the City of San José, partially regulates the flows of Upper Penitencia Creek. Flows in other creeks are largely dependent on groundwater, springs, raw water turnouts, or piped urban runoff.

Percolation ponds have been maintained by the SCVWD throughout the watershed to actively promote aquifer recharge in order to minimize future subsidence and saltwater intrusion. These ponds of water are held over naturally occurring sandy gravel beds (Santa Clara Basin Watershed Management Initiative 2003). The four main groundwater recharge areas in the Coyote Watershed are the Penitencia, Overfelt, Ford Road, and Coyote ponds. The Penitencia percolation ponds receive water from Upper Penitencia Creek and the South Bay Aqueduct (which, in turn, receive water from the Sacramento–San Joaquin Delta). The Overfelt ponds are also near the lower reaches of Upper Penitencia creek. The Ford Road and Coyote ponds receive water from Coyote Creek, Anderson Reservoir, and the Central Valley Project supplied by the San Felipe Division of the Bureau of Reclamation. Between Anderson Reservoir and the Coyote Narrows, flows into Coyote Creek are an in-stream source of recharge to the Coyote Creek groundwater basin (Santa Clara Valley Water District 2002a). Flows from Upper Penitencia Creek also provide in-stream recharge in the basin.

## **Guadalupe River Watershed**

The Guadalupe River Watershed headwaters originate on the west side of Santa Clara County in the Santa Cruz Mountains and encompass approximately 109,000 acres, 59,000 acres of which (54%) are in the study area. The Guadalupe River discharges to the southern terminus of San Francisco Bay via the Alviso Slough near the community of Alviso (Santa Clara Basin Watershed Management Initiative 2003). The lowermost reach by San Francisco Bay and the uppermost watershed are excluded from the study area.

Tributaries to the Guadalupe River include Los Gatos, Ross, and Canoas Creeks. Los Gatos Creek is the largest tributary to the Guadalupe River and joins the river near downtown San José (Santa Clara Basin Watershed Management Initiative 2003). Reservoirs in the Guadalupe River watershed include Almaden, Guadalupe, and Calero Reservoirs. All three reservoirs are relatively small;

Calero Reservoir has a capacity of 9,934 acre-feet, while Guadalupe and Almaden have capacities of 3,415 and 1,586 acre-feet, respectively. Runoff is captured in the reservoirs in the winter months and stored for use in the summer dry months. Water released from the reservoirs and the SCVWD's Almaden Valley pipeline maintains perennial stream habitat downstream on Guadalupe Creek to the Los Capitancillos percolation ponds and Guadalupe River. Lexington and Vasona Reservoirs regulate flows in Los Gatos Creek. Vasona Reservoir is the smallest maintained by SCVWD, at 400 acre-feet. Lexington Reservoir is not included in the Plan study area. Releases are made from Lexington Reservoir during summer for groundwater recharge, and flows are percolated into the groundwater upstream of the confluence with the Guadalupe River (Jones & Stokes 2002).

Nine percolation pond facilities are located in the Guadalupe Watershed. Each of the facilities has multiple ponds. Six of the nine percolation pond facilities are charged from Los Gatos Creek, with the rest charged from the Guadalupe River or Guadalupe Creek (Santa Clara Valley Water District 2002b).

## **Pajaro River Watershed**

The Pajaro River is the largest coastal stream between San Francisco Bay and the Salinas Watershed in Monterey County (RMC 2005). Approximately 11.7 miles of the upper Pajaro River fall within the Plan study area in southern Santa Clara County. The Pajaro River eventually enters the Pacific Ocean at Monterey Bay. Pacheco, Uvas, Llagas, and Pescadero Creeks are the primary tributaries to the Pajaro River in the study area and cover an approximately 230,000 acre region. The creeks in this watershed are the only ones in Santa Clara County that flow southward for their entire length (Santa Clara Valley Water District 2002c). All of the Llagas Watershed (65,365 acre) and all of the Uvas Watershed (55,916 acres) are within the study area. Most of the Pacheco Watershed (100,742 acre) and a small portion of the Santa Cruz Mountains Watershed (i.e., the watershed of Pescadero Creek) are also included in the study area (7,269 acres).

Channels in the Llagas Creek watershed have been modified substantially to convey flood flows. Some channels are natural, while others in the urban areas of Morgan Hill, San Martin, and Gilroy are highly modified and largely unvegetated (U.S. Department of Agriculture 1982). Between U.S. 101 to Santa Theresa Blvd, portions of Uvas Creek have also been modified with levees and armoring to convey flood flows (J. Abel pers. comm. 2010). In addition, extensive quarry operations from the 1940s to 1960s in the Christmas Hill Park area have affected channel morphology of Uvas Creek (J. Abel pers. comm. 2010). Pacheco Creek remain largely unmodified by flood control projects.

There are three reservoirs in the Pajaro Watershed within the study area: Uvas and Chesbro, owned by SCVWD, and the Pacheco Reservoir, owned by the private Pacheco Pass Water District. Uvas Reservoir impounds water along Uvas Creek and has a capacity of 9,835 acre-feet. Chesbro Reservoir occurs along Llagas Creek and has a capacity of 7,945 acre-feet. SCVWD maintains

percolation ponds below Chesbro Dam along Llagas Creek (U.S. Department of Agriculture 1982).

Soap Lake is a natural floodplain basin, approximately 9,000 acres in size, on the Pajaro River, divided between Santa Clara and San Benito Counties at the southern edge of the Santa Clara Valley and the northern edge of the Bolsa Valley. During significant rain events, Soap Lake is a floodplain that acts as a retention basin, capturing flows from Pacheco Creek and Tequisquita Slough. The lake discharges primarily to Miller Canal, which discharges to the Pajaro River near the mouth of Llagas Creek; at high flows a portion of the discharge flows to the old upper Pajaro River, which was bypassed by Miller Canal. During moderate floods, Soap Lake may extend just beyond San Felipe Lake in San Benito County. During 100-year events, Soap Lake may expand to several thousand acres, encompassing the lower reaches of Llagas Creek and Uvas Creek (RMC 2005). A recent study has determined that Soap Lake is vital to reduce flooding risk in the lower Pajaro River in Monterey County and within the cities of Castroville and Watsonville (RMC 2005).

## Hydrologic Modifications

Due to urbanization and water-supply projects throughout the County, the natural hydrology of many streams and watersheds has been altered. Modification of natural flow patterns is the result of water storage and release from reservoirs and percolation ponds, increased runoff, channel modification, groundwater withdrawal, land subsidence, hydraulic structure placement, vegetation clearing, and urban development. The resulting stream hydrograph reduces peak winter flows and provides additional water during drier summer months. This alteration of the hydrograph is clearly evident in Coyote Creek. **Figure 3-7** shows mean monthly streamflow in Coyote Creek before and after the construction of Anderson Dam. In the winter, Anderson Reservoir captures rainfall and releases winter flows that are reduced and less variable from the historic condition. During the dry season, reservoirs also release water in order to maintain flows during the summer months, increasing flows compared to historic conditions. The net result has been a “flattening” of the hydrograph and reduction in the historic seasonal variations in flows. Increased summer flows and restrictions on channel meandering has also increased the density of riparian vegetation (Grossinger et al. 2006), altering ecosystem function.

Runoff from streams and surrounding areas becomes less attenuated (i.e., flashier) as the density of urban development increases. Replacement of natural vegetation with impermeable urban surfaces such as asphalt, concrete, and roofs; and highly efficient drainage systems increases the volume of runoff and the peak flow rate for frequent events (Santa Clara Valley Water District 2001). The decreased infiltration and increased runoff associated with urbanization can cause the size of peak floods to increase (County of Santa Clara Planning Department 1969).

Flooding due to increased runoff has changed historical stream morphology and flow patterns in the watersheds. While some of the stream channels in the upland

areas are still natural, most of the tributaries within the valley floor area of the watershed have been significantly modified to optimize flood conveyance. Many types of channels have been constructed for controlling high flows, including earthen levees, trapezoidal concrete channels, floodwalls and culverts (Jones & Stokes 2000). Design and operation of flood-conveyance elements were historically focused on conveying 100-year storm flows and to accommodate new development adjacent to these stream corridors (Santa Clara Valley Water District 2002a).

Channelization projects designed to increase hydraulic capacity often expanded channel dimensions and straightened channel meanders. The construction of channels to unnatural dimensions leads to increased sediment deposition as the stream attempts to re-create smaller, equilibrium dimensions. For example, the lower reaches of Coyote Creek and the Guadalupe River have been channelized and the streams are now contained between several miles of earthen levees.

Intensive withdrawal of groundwater from the alluvial aquifers in the San José area between the early 1900s and mid-1960s caused a decline in groundwater levels and resulted in substantial land subsidence. For example, 12.7 feet of subsidence was measured in San José from 1916 to 1969 (Poland 1969; Poland and Ireland 1988). Subsidence was one important factor that led to increased flooding in the northern Santa Clara Valley in the twentieth century. Since 1967, recovery of the water table has been substantial because of increases in imported water by SCVWD, the use of percolation ponds and river systems to recharge the aquifer (in part with this imported water), and favorable local-water supply resulting in decreased withdrawal and increased recharge.

Percolation ponds provide holding areas where water slowly recharges groundwater to primarily offset pumping that exceeds the natural recharge. Percolation ponds also compensate for the reduced rates of infiltration from urban development and other impermeable land uses. The SCVWD releases locally conserved and imported water to 71 off-stream percolation ponds that range in size from less than 1 acre to more than 20 acres. Through local streams and percolation ponds, the SCVWD recharges the groundwater basin with about 157,000 acre-feet of water each year (Santa Clara Valley Water District 2002b). Groundwater recharge keeps some streams flowing year round, when under natural conditions, the streams would be dry during the summer into the early fall. Very little published information exists to present a current groundwater budget detailing inflows and outflows for the Santa Clara Valley basin (California Department of Water Resources 2004).

## 3.3 Ecosystems, Natural Communities, and Land Cover

### 3.3.1 Definitions

The following definitions are provided to clarify terms used in the NCCP Act. These terms are also found in the glossary (**Appendix A**).

### Ecosystem Functions and Services

In order for this Plan to be approved, the NCCP Act requires CDFG to make findings that this Plan conserves, restores, and manages representative natural and seminatural landscapes to maintain the ecological integrity of large habitat blocks, ecosystem function, and biological diversity (California Fish and Game Code Section 2820(a)(4)(A)). For the purposes of this Plan, *ecosystem function* is defined as processes operating at the ecosystem level, such as the cycling of matter, energy, and nutrients that maintain the characteristics and biodiversity of an area (Mooney et al. 1995). Ecosystem functions include such biological and physical processes as hydrological regulation, dispersal, predation, herbivory, pollination, decomposition, nutrient cycling, soil disturbance, and energy fluctuations.

The general ecological concept of ecosystem function as it applies to conservation has evolved in the last two decades to focus on the subset called ecosystem services<sup>6</sup>, and a shift in management strategy from protection of reserves to sustainability and stewardship of the human-occupied landscape (Daily and Matson 2008; Cowling et al. 2008). Ecosystem services include maintenance of habitat for endangered species as well as production of clean water and air, aesthetics for tourism, forage for livestock, and climate stabilization. They have human economic value that can generate payments as incentives to maintain those services. This newer concept recognizes the vital roles of people, including planners, managers, and consumers, in a vision of conservation for California rangelands (Daily 2011).

### Biological Diversity

The NCCP Act calls for the protection of species diversity on a landscape or ecosystem level through the creation and long-term management of habitat reserves or other measures that provide equivalent conservation of covered species appropriate for land, aquatic, and marine habitats within the area (California Fish and Game Code Section 2820(a)(3)). The NCCP Act also calls

---

<sup>6</sup> Jack et al (2008) defines ecosystem services as the benefits that people derive from ecosystems, including commodities and regulating, supporting, and cultural services.

for maintaining biological diversity through conservation, restoration, and management of natural and seminatural landscapes.

*Biological diversity* or *biodiversity* is defined in this Plan as the variety of organisms considered at all levels, from genetic variants of a single species through arrays of species to arrays of genera, families, and higher taxonomic levels (Lincoln et al. 1998).

## Ecological Integrity

The NCCP Act calls for sustaining the effective movement and interchange of organisms between habitat areas in a manner that maintains the ecological integrity of the habitat areas within the study area (California Fish and Game Code Section 2820(a)(4)(E)). The NCCP Act also calls for maintaining the ecological integrity of large habitat blocks through conservation, restoration, and management of natural and seminatural landscapes.

Ecosystems have *ecological integrity* when their native components are intact, including abiotic components, biodiversity, and ecosystem processes. This Plan seeks to support the goal of ecological integrity by protecting large blocks of habitat such that the various components of functioning ecosystems are maintained in an interconnected area.

## Environmental Gradients

The NCCP Act calls for incorporating a range of environmental gradients such as slope, elevation, aspect, and coastal or inland characteristics to provide for shifting species distributions due to changed circumstances (California Fish and Game Code Section 2820(a)(4)(D)).

This Plan defines *environmental gradient* as a shift in physical and ecological parameters across a landscape, such as changes in topography, climate, geology, land cover types, and natural communities.

## Natural Communities

*Natural communities* are a collection of species that co-occur in the same habitat or area and interact through trophic and spatial relationships. Communities are typically characterized by reference to one or more dominant species (Lincoln et al. 1998). The NCCP Act calls for the protection of natural communities on a landscape or ecosystem level through the creation and long-term management of habitat reserves or other measures that provide equivalent conservation of covered species appropriate for land, aquatic, and marine habitats within the area (California Fish and Game Code Section 2820(a)(3)). In the Santa Clara Valley Habitat Plan study area, seven natural communities and two additional land cover

types (irrigated agriculture and developed) are defined that will be discussed further in the chapter.

The term *rangeland* is used in this Plan to refer to the collection of multiple natural communities on which the indigenous vegetation is predominantly grasses, grass-like plants, forbs or shrubs that are grazed or have the potential to be grazed, and which is used as a natural ecosystem for the production of grazing livestock and wildlife. Rangelands include natural grasslands, savannas, shrublands, many deserts, steppes, tundras, alpine communities and marshes (Allen et al. 2011). Rangelands usually occur in areas not suitable for cultivation, irrigation, residential development, industrial development, or timber production. The rangelands within the study area occur primarily in grassland land-cover types but also include oak woodlands, riparian forest, and seasonal wetlands. Rangelands in the study area are considered “working rangelands” because numerous economic activities (including livestock grazing) take place there.

## 3.3.2 Methods

### Data Collection

Sources used to map and describe the physical setting of the study area are listed below.

- U.S. Geological Survey data on topography and hydrology.
- Geologic maps of the area (Wagner et al. 1991; Helley et al. 1994).
- Geologic map, Santa Clara County, California. California Division of Mines and Geology, scale 1:62,500 (Brabb and Dibblee 1974).
- Preliminary map of Santa Clara Valley serpentines [soils] (unpublished), scale 1:50,000 (Dibblee 1973, 1977).
- Preliminary geologic map of the Mt. Madonna quadrangle, Santa Clara and Santa Cruz Counties, California. U.S. Geological Survey Open-File Report [OF-73-59], scale 1:24,000 (Dibblee 1973).
- Soil survey information (U.S. Soil Conservation Service 1968).
- Other published information (Hickman 1993; Alt and Hyndman 2000; Santa Clara Valley Water District 2006).
- Springs and rainfall data from USGS (California Spatial Information Library 1997).
- Watershed data from California Interagency Watershed Map (CalWater version 2.2.1) (California Interagency Watershed Mapping Committee 1999).

Topography, hydrology, and soil data were downloaded from agency websites and imported into ArcInfo, where files were clipped and converted into the projection for the study area.

## Land Cover Mapping

One of the primary data sources for this Plan is a detailed geographic information systems (GIS)-based map of land cover types within the study area. A *land cover type* is defined as the dominant character of the land surface discernible from aerial photographs, as determined by vegetation, water, or human uses. Land cover types are the most widely used units in analyzing ecosystem function, habitat diversity, natural communities, wetlands and streams, and covered species habitat. Data sources, mapping standards, and the classification and interpretation of land cover types are discussed below.

### Data Sources

The following are the primary sources of information for the land cover mapping in the study area.

- True-color aerial photographs (resolution of 2 feet<sup>7</sup>) flown in December 2003 (acquired from AirPhoto USA).
- True-color aerial photographs for non-urban portion of the study area (resolution of 9 inches) flown in March 2001 (provided by Santa Clara Water District).
- Serpentine soils and serpentine geology digitized from the map sources listed above.

The ancillary data sources listed below were used to obtain information not available in the primary sources and to check the mapped information for accuracy.

- True-color aerial photographs (resolution 1.5 foot) flown in December 2005 (acquired from AirPhoto USA)<sup>8</sup>.
- National Wetlands Inventory Maps (scale 1:65,000) from the U.S. Fish and Wildlife Service for a portion of the study area based on color-infrared photographs taken in 1982–1987.
- Streams (Produced by SCVWD in 2006–2007; see discussion below).
- Local roads (Santa Clara County data set).
- Coyote Valley Specific Plan vegetation data developed from site visits (City of San José 2004).
- Soil survey mapping (U.S. Soil Conservation Service 1968).
- Historical locations of valley oak; GIS layer digitized from the 1:62,500 Wieslander Vegetation Type Map, a dataset of photos, species inventories, and plot maps compiled in the 1920s and 1930s (California Department of Forestry and Fire Protection 1992).

<sup>7</sup> Each cell represents an area on the ground of approximately 2 feet by 2 feet, or 4 square feet.

<sup>8</sup> December 2005 air photos were not made available until March 2006. These photos could not be used as the primary air photo source because the land-cover mapping process started in November 2005.

- Vegetation maps of open space preserves adjacent to the western portion of the study area developed from air photo interpretation (Midpeninsula Regional Open Space District 2006).
- Vegetation map of the Coyote Creek Parkway County Park developed from remote sensing (County of Santa Clara Parks and Recreation Department 2004a).
- Land cover map for the San Francisco Public Utilities Commission's Alameda Watershed lands in Santa Clara and Alameda Counties (adjacent to the northern edge of the study area) developed from air photo interpretation (Jones & Stokes 2005).
- Current land cover maps for large projects in the study area:
  - The Castro Valley Ranch EIR, an approximately 8,500-acre site in the southwest corner of the study area, developed from site visits (H.T. Harvey & Associates 2006).
  - Mapping of freshwater and seasonal wetlands in Coyote Valley (City of San José 2007).
  - Land cover mapping of the proposed Lucky-Day Wildlife Conservation and Wetland Mitigation Bank (WRA Environmental Consultants 2008), north of Gilroy.
  - Land cover and habitat mapping for Young Ranch on Coyote Ridge (WRA Environmental Consultants 2012).
- Historical tideline data from Coyote Creek Historic Ecology Report (Grossinger et al. 2006) and historical land cover data from the study area (Grossinger et al. 2006; San Francisco Estuary Institute 2008).

In addition to using existing data sets, ICF biologists conducted field visits in accessible portions of the study area to develop and verify land cover mapping. An initial field visit was conducted on December 15, 2005 to develop the land cover classification and to perform preliminary verification of aerial photograph signatures. Other field visits were conducted on April 20–21, May 3–5, May 11–12, and May 24–25, 2006 to verify land cover types and consistency of mapping, and to collect additional data for land cover type descriptions. Initial mapping was verified by visual inspection from locations accessible by public roads and roads on state-owned and private lands for which access permission had been obtained. Areas were selected for field verification on the basis of the land cover types present and accessibility.

Access was difficult in many parts of the study area due to extensive private lands and few public roads. Access in the western portion of the study area was sufficient to verify the different land cover types that occurred there. Access in the central eastern portion of the study area was more limited, but also allowed most land cover types to be visited. Access to the extreme northeast, east, and area south of SR 152 was not possible due to extensive private holdings and lack of approvals for access. There were no unique land cover types in these areas so we believe that this lack of access did not compromise the land cover mapping.

Once field visits were conducted, land cover mapping was revised on the basis of field findings.

## Land Cover Type Classification

A classification system for land cover types was developed for the study area based primarily on the widely used classification system of the CDFG (California Department of Fish and Game 2003a, 2007), which in turn is based on the vegetation classification system developed for the Manual of California Vegetation (Sawyer and Keeler-Wolf 1995). Additional input was obtained from the sources listed below.

- Holland (1986) and Mayer and Laudenslayer (1988, 1999).
- Current regional and local mapping projects such as Coyote Ridge (California Native Plant Society 2003), Sierra Azul Open Space Preserve (Midpeninsula Regional Open Space District 2006), and the land cover map for the San Francisco Public Utilities Commission's Alameda Watershed lands in Santa Clara and Alameda Counties, adjacent to the study area (Jones & Stokes 2005).
- Field visits by ICF senior biologists.

The proposed system (**Table 3-1**) has been adapted to incorporate classification systems used by the Local Partners with input from vegetation and wildlife specialists familiar with the study area. The land cover classification was developed with the criteria listed below.

- Each land cover type must be distinguishable on the digital aerial photography based on a unique and consistent signature, or with the use of ancillary data such as soil types or geologic substrate.
- Each land cover type should be useful to the Plan in terms of defining the location and extent of an important vegetation type, habitat for covered species, or a distinct type of development.
- The land cover type classification should be compatible with existing local, regional, and national land cover classification schemes when possible.

A list of land cover types is given in **Table 3-1**. A comparison ("cross-walk") between land cover types and common vegetation classification systems is presented in **Table 3-2**.

## Mapping Procedures

ArcGIS 9.0 software was used to create a GIS dataset of land cover types. The land cover classification also defined the minimum mapping unit that was used for each land cover type. *Minimum mapping units* are the smallest area mapped for each type. Minimum mapping units range from 0.25 acre for wetland and riparian land cover types to 10 acres for most other land cover types. This range

of minimum mapping units is sufficient for regional conservation planning and balances the need for high resolution (lower minimum mapping unit) with schedule and budget limitations (higher minimum mapping unit). Minimum mapping units are also limited by the resolution of the imagery and the distinctiveness of the land cover signature relative to adjacent land cover.

A 10-acre minimum mapping unit was used for all land cover types, except for the land cover types noted below.

- Serpentine bunchgrass grassland and mixed serpentine chaparral, which were mapped at a 1-acre minimum mapping unit.
- All riparian, wetland, and aquatic types, which were mapped at a 0.25-acre minimum mapping unit.
- Serpentine seeps and rock outcrops, which had no minimum mapping unit (but due to air photo resolution had a likely minimum mapping unit of 0.1–0.25 acres).

The mapping process involved digitizing polygons on screen (a process known as “*head-up digitizing*”) from the primary aerial photographs described above, followed by field verification and a formal accuracy assessment.

Polygons were digitized for areas with distinct image signatures that met minimum mapping unit requirements. Digitizing was completed on-screen by botanists familiar with the study area, and well trained and experienced with this mapping procedure from other HCPs and NCCPs in northern California. Digitizing was conducted while viewing the aerial imagery at mapping scales of 1:4,800 to 1:6,000. The botanists were provided with grids of 0.25 acre and 10 acres to assist in maintaining the minimum mapping units during digitization. Once digitized, polygons were assigned to land cover types on the basis of the criteria in the land cover type definitions (described below under each land cover type).

During the mapping process, polygons with uncertain land cover types were flagged for future field verification. Once the mapping was complete, the botanists verified these ambiguous polygons in the field where access was available.

Serpentine bunchgrass grassland and serpentine chaparral were mapped based on the intersection of annual grassland and chaparral, respectively, with the serpentine soils and geology layers (**Figure 3-4**), and verified in the field where possible. Some areas along Coyote Ridge that were mapped as having serpentine soils or geology were excluded from the serpentine bunchgrass grassland or serpentine chaparral land cover layers because of a lack of field evidence of these plant communities (S. Weiss pers. comm.). Serpentine bunchgrass grassland mapping was refined based on site specific mapping when available (e.g., WRA Environmental Consultants 2009). Boundaries of aquatic features (ponds, reservoirs) were digitized based on the March 2001 photograph when water levels were higher than in the December 2003 image. Recent urban and

agricultural development was updated based on the December 2005 aerial photography.

Ancillary information was used to supplement the land cover information acquired by aerial photograph interpretation. National Wetlands Inventory maps were used to check and augment the wetlands mapping, especially for isolated ponds and seasonal wetlands. Data from SCVWD were used as the stream layer for the area. In 2006–2007, SCVWD staff digitized all stream reaches in the study area using USGS Digital Elevation Models (DEM) overlaying color orthophotos. Mapped signatures for specific land cover types were also compared with vegetation maps of the Sierra Azul Open Space Preserve (Midpeninsula Regional Open Space District 2006) to verify the accuracy of the current mapping effort.

## Accuracy Assessment

A formal accuracy assessment could not be conducted for all land cover types due to the inaccessibility of large areas of the study area. However, a field accuracy assessment was performed for all land cover types on the Santa Clara Valley floor to quantify the reliability of the mapping. For land cover types with fewer than 30 polygons, all accessible polygons were field verified. For land cover types with more than 30 polygons, a random sample of 30–40 polygons was selected and verified if accessible. A total of 306 polygons were field verified during this accuracy assessment. Field verification was conducted by two staff, including one botanist. Field verification was performed by visual observation of land cover units from publicly-accessible roads using binoculars and views from vantage points where possible.

A polygon was classified in one of three ways. The first classification was “no change”, meaning the polygon was mapped correctly. The second classification was “error”, indicating a misinterpretation from the aerial imagery. The third classification was “change,” indicating a land use change that occurred after the aerial photographs were taken. The resulting map accuracy for the Valley floor was 73% when calculated by number of polygons. The map accuracy for the Valley floor was 89% when calculated by polygon area (31,258 acres were checked)<sup>9</sup>. All errors identified were corrected in the final land cover map.

**Table 3-3a** indicates the results of the accuracy assessment of the land cover mapping in the Valley floor by polygon. **Table 3-3b** provides the same results by acreage of land cover type.

Land cover types outside the Valley floor were spot checked throughout the rest of study area in a series of field visits from public roads. Based on the accuracy assessment and these site visits, a qualitative estimate of overall confidence in the mapping of all land cover types is presented in **Table 3-4**. Factors that were considered in this subjective estimate included:

<sup>9</sup> The error rate for urban and agricultural land-cover types may not be a good indication of the error rate for natural land-cover types due to the substantial differences in polygon size, complexity, and patterns of air photo signatures.

- the quantitative results of the accuracy assessment,
- the ability of field crews to visit a representative sample of polygons and verify land cover signatures and mapping units, and
- the distinctiveness of the air photo signature during the season of the photo flight.

## Fish Habitat Assemblage Data

A map was developed of native and nonnative fish assemblages and aquatic habitat types throughout the major stream systems in the study area to characterize these important stream communities. Data was first developed to support SCVWD's Stream Maintenance Program. Dr. Jerry Smith of San José State University updated the map in July 2006 for the Science Advisors report of the Habitat Plan to reflect barrier removal and sampling results that occurred in the intervening years since the original map was created (Spencer et al. 2006). The map was then further revised and updated in 2007 by Dr. Smith and Jae Abel, a senior fisheries biologist at SCVWD. Jae Abel then adapted the map so that it corresponded to the new GIS stream data layer developed for the study area by SCVWD in early 2007. Ten categories were defined of fish assemblages and aquatic habitat types. These habitat categories and the fish assemblage map are described in **Appendix L**. The data presented in the appendix are to support the descriptions of natural communities in the study area. These data will not be updated as part of Plan implementation.

### 3.3.3 Covered Species

#### Ecology and Distribution

Detailed *species accounts* of each of the 19 covered species (**Table 1-2**) are provided in **Appendix D**. These accounts summarize ecological information, distribution, status, threats, population trends, and conservation and management activities in the study area. The accounts represent the best available scientific data for each species on which to base this Plan. The species accounts are not intended to summarize all biological information known about a species. Rather, each account summarizes scientific information that is relevant to this Plan. Each account is designed for easy reference; all literature cited within the account is provided within it. The biological data in these accounts form the basis for the impact analysis (Chapter 4) and conservation strategy (Chapter 5) in this Plan.

Land cover types are the basic unit of evaluation for habitat modeling, analyzing potential impacts, and developing conservation strategies for covered species. Most covered species are associated with one or more land cover types (**Table 3-5** for wildlife, **Table 3-6** for plants). These land cover type associations, plus other habitat features, were used to develop habitat distribution models for 15 of the 18 covered species that provide additional information on species impacts and conservation needs.

## Habitat Distribution Models

Habitat distribution models were developed for select covered species to predict where within the study area covered species occur or could occur based on known habitat requirements. These models have been used to assist in quantifying impacts of covered activities on covered species and to assist in developing the conservation strategy<sup>10</sup>. Alternative reserve and restoration designs were evaluated against each covered species model, when available, to help ensure that regulatory standards and biological goals for these species will be met and that conservation for each species is maximized. Habitat distribution models for 15 of the covered species are described in detail in the respective species account (**Appendix D**). Methods used for all models are described below.

Because of model limitations (see *Model Limitations* discussion below), models could not be developed for three of the 18 covered species. For some species, the number of known occurrences within the study area was so low that habitat potential could not be modeled with confidence (e.g., Tiburon Indian paintbrush). Some plant species have very specialized habitat requirements that could not be modeled given the available data (e.g., coyote ceanothus, Santa Clara Valley dudleya). For species without models, development of the conservation strategy ultimately took a more conservative approach than for species with models. For example, field surveys were required more often in suitable habitat for species without models than for species with models. Information in the species accounts was adequate to develop the impact analysis and conservation measures for the species without habitat models.

The habitat map for Bay checkerspot butterfly, a covered species, was developed based on extensive field surveys. This map is described in more detail in the species account and should be considered as a habitat map rather than a predicted habitat distribution.

## Model Structure and Development Methodology

The 15 habitat models described in the species accounts were designed to estimate the extent and location of key habitat characteristics of each species and to be repeatable and scientifically defensible, while remaining as simple as possible. The models are spatially-explicit, GIS-based “expert opinion models” based on identification of land cover types that provide important habitat for these species (**Table 3-5**). Land cover types were identified as suitable habitat based on the known or presumed habitat requirements and use patterns of each species. When supported by appropriate data, the models also incorporate physical parameters including

---

<sup>10</sup> Habitat distribution models have been developed on a regional scale using regional data. The models are intended for use in regional planning and do not necessarily provide accurate site-specific species information. For project planning, model results must always be field-verified.

- elevation limits using an absolute limit when data supported a clear limit, or one or more of seven elevation categories (0–500, 500–1000, 1001–1500, 1501–2000, 2001–2500, 2501–3000, 3001–3500 feet msl) when data were insufficient to determine an absolute limit,
- soil type based on eight broad categories (clay, loam, silt, sand, coarse sand, rock, other, unknown [U.S. Soil Conservation Service 1968]),
- presence or absence of serpentine soils and/or serpentine geology (Dibblee 1973, 1977; Brabb and Dibblee 1974)
- slope steepness based on three categories (flat 0–10%, moderate 11–25%, steep >25%), and
- ecoregion subsection (U.S. Forest Service 1997; see **Figure 3-8**).

Further, in some cases, perimeter zones that were used to designate habitat are defined by a certain distance from a land cover type. For example, the California red-legged frog model uses upland habitat for aestivation (summer hibernation) and dispersal, but the probability of use decreases with increasing distance from suitable breeding sites (e.g., ponds, streams).

Primary and secondary habitats for wildlife were designated according to type of habitat use. Land cover types used for breeding were designated as primary habitat. Secondary habitat includes other important habitats used for foraging, aestivation, migration, movement, or dispersal. This secondary habitat is no less important for the species than primary habitat but merely characterizes different habitat function for the species.

Determinations of suitable land cover types and additional physical parameters were based on available data from peer-reviewed scientific literature, survey reports, and environmental documents. Local survey data were used whenever possible to define model parameters. When data were inconclusive or contradictory, conservative values were assumed in estimating suitable habitat. See below for a discussion of the model limitations.

## Covered Species Locations

Documented occurrences of covered species within the study area were used to validate and refine the models. Sources of occurrence data are listed below.

- California Natural Diversity Database (2008 and 2012 data).
- Plant occurrence records from 2004 SCVWD surveys of their facilities (J. Hillman pers. comm.).
- A 1999 survey of foothill yellow-legged frog in Santa Clara County (H.T. Harvey & Associates 1999).
- Least Bell's vireo survey data from SCVWD (Santa Clara Valley Water District 2002d, 2003, 2004).

- Rare plant and special-status wildlife survey data from field work conducted in 2005-2006 east of San José on an approximately 8,000-acre property owned by United Technologies Corporation (UTC) (T. Marker pers. comm.).
- Recent plant occurrence records from the California Native Plant Society (K. Bryant pers. comm., 2006–2007 data).
- Bay checkerspot butterfly survey data from field work conducted between 2009 and 2011 on the 2,150-acre Young Ranch site (WRA Environmental Consultants 2012).

Occurrences that fell outside a model's predicted habitat distribution were evaluated to determine whether they indicated flaws in the model or were anomalous or erroneous points. Erroneous points were deleted; anomalous points were retained but were not used to verify model results. The aerial photographs were examined to assess the significance of extreme outliers.

The majority of the records come from the CNDDDB (California Natural Diversity Database 2008, 2012). Occurrences that have been documented since 1980 were assumed to be extant unless they were on sites that have obviously been converted to other land uses. These recent occurrences were used to verify habitat models. These occurrences are displayed as either *precise locations* or *general locations*, described in more detail in *Occurrence Data Precision* below. Any occurrence before 1980 is considered a *historical location*<sup>11</sup> and is not shown on the habitat model, with a few exceptions. Historical occurrences were considered if the land use at the location has clearly not changed since the sighting (e.g., a state park). Historical occurrences presumed extant were also used to supplement models with few recent occurrence records.

## CNDDDB Data Limitations

CNDDDB records represent the best available statewide data but are limited in their use for conservation planning. CNDDDB records rely on field biologists to voluntarily submit information on the results of surveys and monitoring. As a result, the database is biased geographically toward areas where surveys have been conducted or survey efforts are greater (many areas have not been surveyed at all and this is not reflected in the database). The database may also be biased toward species that receive more survey effort. For example, there have been more surveys for California red-legged frog than other special-status wildlife because it is a listed species. Conspicuous diurnal species such as raptors likely receive greater survey effort than nocturnal species such as bats. Plants typically receive less survey effort than wildlife.

<sup>11</sup> The year 1980 was selected as a somewhat arbitrary cutoff date. We assume that before this year occurrence records are more likely to be inaccurate or no longer present than occurrence records after this year. 1980 is also the cutoff date used by The Nature Conservancy in their internal ecoregional planning process in California.

## Occurrence Data Precision

Data that are reported to the CNDDDB are done so with varied precision. Some occurrences are very well documented with explicit locations (e.g., GPS coordinates) while others are reported with more general location information. CNDDDB staff qualitatively categorize each occurrence record into one of two categories: *specific* and *non-specific* (California Natural Diversity Database 2008).

A *specific* occurrence has sufficient information to be located on a standard USGS 7.5-minute quadrangle map. This information may be based on political or natural features but has been very well described by the observer. These occurrences are mapped by CNDDDB as points with an 80-meter radius or as specific polygons when information allows. For the purposes of this Plan these occurrences are mapped as points and are labeled as *precise location* on the habitat distribution models.

A *non-specific* occurrence is a species occurrence that has been documented by the observer in very general terms. Sometimes the precise location is unclear or lacks critical information that does not allow it to be mapped accurately. These occurrences are mapped by CNDDDB as circular features with a radius of 0.1, 0.2, 0.4, 0.6, 0.8, or 1.0 mile. These occurrences can also be mapped with non-specific polygons, such as the boundary of a park where an occurrence is known to occur. For the purposes of this Plan these occurrences are mapped as points and are labeled as *general location* on the habitat distribution models.

## Model Uses and Limitations

The habitat distribution models are intended to be used only for planning purposes at the scale of the study area. The precision of the habitat distribution models is limited by several factors, including the 10-acre/0.25-acre minimum mapping units used to map each land cover type. Areas of suitable habitat smaller than the mapping thresholds were not mapped and could therefore not be incorporated into the models. This constraint limited the degree of resolution of some habitat features potentially important to some species. Therefore, these models should only be used at the regional scale (i.e., scale of the study area) rather than for site-specific planning. In addition, these models are not intended to be used for project-level CEQA analysis, including determinations on the level of CEQA compliance required (e.g., whether a Categorical Exemption is warranted).

The habitat distribution models were limited to distinguishing habitat uses based on key life history requirements such as breeding, foraging, or dispersal that are tied to land cover types. The data do not allow for further distinctions of habitat quality on a regional scale. To account for these limitations, conservative estimates of habitat parameters were used. This approach tends to overestimate the actual extent of suitable or required habitat for this species, but is consistent with current conservation planning practices when data are limited (Noss et al. 1997).

For the most part, the models are used in this plan to denote suitable habitat. Suitable habitat was assumed to be occupied for the purposes of the take analysis and conservation strategy. This approach is justified because of the limitations in occurrence data described above and the infeasibility of determining presence or absence on such a large scale. To conclusively determine absence, the Wildlife Agencies typically require extensive protocol-level surveys in the field, sometimes spanning several years.

## Alternative Approaches to Habitat Modeling

In developing the habitat distribution models, we considered other potential approaches. For example, the Science Advisors recommended that statistical modeling techniques be considered for determining species habitat relationships within the study area. Because the study area does not include any data on locations where species are absent, statistical modeling would have to be done with “presence-only models” (Hirzel et al. 2002; Hirzel and Arlettaz 2003; Guisan and Thuiller 2005; Elith et al. 2006; Guisan et al. 2006; Pearce and Boyce 2006). Presence-only models use species presence data to draw inferences about a species’ habitat preference. These models characterize the locations where the species were sighted, calculate habitat scores from those locations, and then compare them to habitat distributions within the entire area of interest. To eliminate the need for absence data, these models either assume that locations without sightings are “pseudo-absences” or that there is something different between sighting locations and all the other locations in the area of interest. After reviewing the data requirements and limitations of these models, we determined that it is not feasible to use them in this HCP/NCCP for the reasons outlined below.

The primary reason we were unable to use these techniques is a lack of available data for the covered species, particularly for species whose habitat requirements in the study area are poorly known and where this technique would be most helpful. For example, the specific habitat needs of San Joaquin kit fox are poorly known in the study area but there are only two observations of this species in the County. Presence-only models typically require at least 50 observations to produce robust results. The only covered species with 50 or more observations in the study area are the California red-legged frog, California tiger salamander, Western burrowing owl, and Western pond turtle. These species have relatively well-understood habitat/occurrence relationships, where an expert opinion model tends to work well. The remaining covered species have approximately 30 or fewer observations in the study, making them inappropriate for presence-only models. We investigated the use of museum records to supplement our occurrence data, but most of the online catalogs did not have recent records for our target species or collectors did not record enough information on habitat associations on the collection records to be useful for a presence-only model. Additional field data collection was also not feasible because of the large scale of the study area and schedule and budget limitations.

We also chose not to use presence only techniques because they are sensitive to the selection of the proper spatial extent and model cell size. The spatial extent

of the model should represent the area sampled (Hirzel et al. 2002; Pearce and Boyce 2006). Because CNDDDB and our other biological occurrence data do not provide information of the area surveyed it would be difficult to define the spatial limits of the model. Without this information the model results would be biased and may give more of an indication of sampling effort rather than actual habitat value (Pearce and Boyce 2006)<sup>12</sup>. For example, if most of the surveys were conducted along roadsides than the spatial extent of the model should only include habitats near roadsides. As a result, the available biological occurrences do not provide enough information to adequately assess what would be an appropriate spatial extent of the model.

These techniques are also sensitive to the type and number of pseudo-absence sites chosen for the analysis (Pearce and Boyce 2006; A. Gelfand pers. comm.). Because presence-only models sample the presence and pseudo-absence locations in different manners the proportion of presence within the sample does not represent the true prevalence of the species. Therefore, presence-only models with differing number of pseudo-absence sites can come up with dramatically different answers (A. Gelfand pers. comm.).

Finally, presence-only models do not propose a model to be estimated and therefore there is no likelihood function that can be used for statistical inference. Instead, presence-only models primarily fit surfaces or use mathematical values to describe a species relationship among a set of candidate sites. Without a defined likelihood function it is not possible to calculate confidence limits, probabilities of significance, or other values that allows the researcher understand the validity of the resulting model (Gelfand et al. 2006).

Instead of using the presence only modeling techniques we have chosen to use expert opinion models provided by species experts. There are several advantages to using these models in the HCP/NCCP planning process. The first benefit is that experts are identifying habitat as inherently good, not good relative to other sites in the area. This means that good sites have a relatively high probability of species occurrence. Second, research has shown that expert opinion models may overestimate suitable habitat (Johnson and Gillingham 2004). It is desirable to overestimate habitat for this plan because it allows for conservative estimates of impact (i.e., err on the side of overestimating impacts) and conservation of suitable areas. Finally, another important advantage of expert opinion models is that the variables and methods used to construct the models are easily understood and are reproducible by knowledgeable GIS practitioners. Application of presence-only statistical models requires specialized software and uses highly specialized statistical techniques.

---

<sup>12</sup> A recent application of this type of model using BIOMAPPER for the East San Diego County HCP/NCCP had over 1,700 data points for peninsular bighorn sheep. The model was highly labor-intensive and was very sensitive to subjective assignments of break points for the correlation classifications. In the end, the model produced results that were only somewhat useful for the HCP/NCCP (S. Fleury pers. comm.).

### 3.3.4 Biological Diversity of Study Area

Species richness, a measure of the number of species in a defined region, is the most readily available measure of diversity and is generally accepted as an index of biological wealth of a region. The number of species that are endemic or unique to a geographic region can provide a measure of biological distinctiveness that is recognized as another measure of biological wealth. When NatureServe examined the diversity and endemism of species for all 50 states in the U.S., California ranked first in both categories (Stein 2002). A unique combination of climate, geography, and topography make California one of the most biologically diverse areas in the world. California is home to several of the nation's biological "hotspots" and has been identified as one of 25 "hotspots" of biodiversity worldwide (Stein et al. 2000).

With a geography that is bordered by the Pacific Ocean, includes San Francisco Bay, and expands eastward into the Sacramento and San Joaquin Valleys, the San Francisco Bay Area is one of only six global hotspots of species rarity in the United States (California Department of Fish and Game 2003b). The nine counties that comprise the Bay Area account for just over 18,000 square kilometers (km<sup>2</sup>), or nearly 5% of the state. Within that 5%, 64 of the 194 natural communities mapped by the California Gap Analysis occur (Wild 2002). This accounts for 33% of the natural communities in California.

More than a dozen major rivers flow into the Central Valley from the Sierra, Cascade, Klamath, and Coast Ranges and converge at the San Francisco Bay Delta; a vast network of wetlands that ultimately empties into Suisun Bay (California Department of Fish and Game 2003b). From the south several more rivers and creeks flow directly into San Francisco Bay, and the Bay itself is lined with tidal wetlands and marshes. These aquatic resources alone support over 200 species of birds, mammals, reptiles, and amphibians (California Department of Fish and Game 2003b). This interface with the San Francisco Bay, coupled with an assortment of upland habitat types with exceptional soil diversity and topography, makes the Bay Area a critical element in the biodiversity of California and of the world.

Situated on the south side of the Bay Area, Santa Clara County represents the extremes of the region. Due to the variation in topography and soil diversity within the County there are a wide array of natural community types and subsequently very diverse flora and fauna. The Santa Clara Basin Watershed Management Initiative (2003) reports that there are 93 identified special-status species in the Santa Clara Basin; 24 of which are either federal or state listed as threatened or endangered. The analysis conducted for this Plan identified 147 special-status species that occur or have the potential to occur in the Plan study area. Biological diversity is realized for all species groups and they are discussed in more detail below.

## Mammals

Like many southwestern states California has a high diversity of mammals due to its large size and unique environments. In fact, California has the most diverse mammal population of any state and has the most endemic mammal species, with 17 (Stein 2002; California Department of Fish and Game 2003b). The south San Francisco Bay region ranks as medium to high in mammalian species rarity and richness within the state (California Department of Fish and Game 2003b). This is largely driven by the salt marshes in the Bay/Delta region and the riparian habitats that drain to them. Of the 195 known mammalian species within the state (Stein 2002) over 20% can be found within Santa Clara County. Between 40 and 47 of those species can be found in Santa Clara Valley and between 48 and 55 can be found in the surrounding Santa Cruz Mountains and Diablo Range (California Department of Fish and Game 2003b). This represents a range between 20% and 28% of the known mammalian species of the state, respectively, for the major geographic features of the Plan study area.

## Birds

California supports one of the most diverse bird populations in the United States. In 2008 the list of birds that spend some part of the year in California was 636 species (California Bird Records Committee 2008). These species range from those who are endemic to California to those that are migratory species that spend part of the year in the state. The south San Francisco Bay region ranks as medium to high in bird species rarity and richness within the state (California Department of Fish and Game 2003b). This is largely driven by the salt marshes in the Bay/Delta region, which are particularly important to many migratory species and the riparian habitats and diverse upland habitats that make up the interior Bay Area. Of the 636 known bird species that either breed in or migrate through the state more than 45% can be found within Santa Clara County. An example of the bird diversity of the study area is provided by the list of 389 species that appear on the Checklist for Birds of Santa Clara County (South Bay Birders Unlimited 2007), 177 of which have been documented breeding in the county (Bousman 2005). Henry W. Coe State Park, the largest open space unit in the study area, supports 162 species of birds that have been confirmed in the park (Pine Ridge Association 2006a).

## Reptiles

California ranks fifth overall in reptile diversity by state in the United States with 86 known species (Stein 2002). The south San Francisco Bay region ranks as low to medium in reptilian species rarity within the state and medium to high in species richness (California Department of Fish and Game 2003b). The distribution of reptilian species within the study area is varied. The Santa Clara Valley supports under 10% of the known reptilian species within the state, while the Santa Cruz Mountains and the Diablo Range support up to 30% (California Department of Fish and Game 2003b). An example of the reptile diversity of the

study area is provided by the list of 27 reptile species found in Henry W. Coe State Park (Pine Ridge Association 2006b).

## Amphibians

California ranks ninth overall in amphibian diversity in the United States with 57 known species (Stein 2002). The south San Francisco Bay region ranks low in amphibian species rarity within the state but medium to high in species richness (California Department of Fish and Game 2003b). The distribution of amphibian species within the study area is varied. The Santa Clara Valley supports less than 10% of the known amphibian species within the state, while the Diablo Range supports 15% and the Santa Cruz Mountains support up to 30% (California Department of Fish and Game 2003b). An example of the amphibian diversity of the study area is provided by the list of 11 amphibian species found in Henry W. Coe State Park (Pine Ridge Association 2006b).

## Freshwater Fish

California ranks 34<sup>th</sup> overall in freshwater fish diversity by state in the United States with 62 known species (Stein 2002). The south San Francisco Bay region ranks low in fish species rarity within the state but medium to high in species richness (California Department of Fish and Game 2003b). The rivers and creeks that drain the Santa Cruz Mountains and the Diablo Range are home to 11 native and 19 nonnative species of fish (Santa Clara Basin Watershed Management Initiative 2003). This represents around 17% of the known freshwater fish species of the state. The most species rich is Coyote Creek with 10 native species followed by the Guadalupe River with seven (Santa Clara Basin Watershed Management Initiative 2003). In the south county, 11 native fish species are found within the Pajaro River watershed, although one of those species, the speckled dace, only occurs in the upper San Benito River, outside of the study area (J. Smith pers. comm. 2007). The abundance and distribution of native species have been reduced significantly over time through human impacts. The interface with the bay provides habitat for several species of anadromous fish including steelhead/rainbow trout, which has been observed in both Coyote Creek and the Guadalupe River (Santa Clara Basin Watershed Management Initiative 2003).

## Invertebrates

There are many thousands of invertebrate species in California, with an estimated 28,000 species of insects alone (California Department of Fish and Game 2003b). The south San Francisco Bay region and most of the study area ranks as medium in invertebrate species rarity within the state (California Department of Fish and Game 2003b). Most of that rarity is driven by unique grassland and scrub habitats that support rare species of plants. These rare plant species in turn support the complex life stages of many insects, especially butterflies and moths.

The biological diversity of invertebrates in Santa Clara County and the study area is largely unknown.

## Vascular Plants

California has the highest overall plant diversity in the United States with almost 8,000 known species (Hickman 1993; Stein 2002). Santa Clara County's moderate size and diverse physical and climatic characteristics create the conditions for a moderate to high level of botanical diversity. Unique habitats like serpentine grasslands in the study area support many special-status species, some of which are covered in this Plan. Of 8,363 plant taxa in California in the CalFlora database, Santa Clara County supports 1,778 native plant taxa and 507 nonnative plant taxa, or 27% of the plant taxa in the state in CalFlora (CalFlora Database 2006)<sup>13</sup>.

The exact number of vascular plants in the study area is unknown. However, floristic surveys of large areas of open space in the study area provide an indication of floristic diversity. For example, the Pine Ridge Association maintains a list of 675 vascular plants found in Henry W. Coe State Park (Pine Ridge Association 2006c).

### 3.3.5 Natural Communities and Land Cover Types

The NCCP Act requires that natural communities within the study area that could be affected by Plan implementation be identified in an NCCP. Natural communities are defined by the vegetative communities within them. Accordingly, the vegetative communities, or land cover types, within each natural community are described below and shown in **Figure 3-9**.

This Plan includes seven natural communities.

- Grassland.
- Chaparral and coastal scrub.
- Oak woodland.
- Riparian forest and scrub.
- Conifer woodland.
- Wetland.
- Open water.

<sup>13</sup> These values somewhat overestimate the actual number of plant taxa in California and Santa Clara County because species are counted separately from each variety or subspecies in the CalFlora database. For example, *Polygonum amphibium* is counted as a unique entry from *Polygonum amphibium* var. *emersum*.

In addition, two broad categories of non-natural land cover types are defined and described below.

- Irrigated agriculture.
- Developed.

The description of each natural community provides information on historic land cover, associated wildlife, ecosystem function, and threats. Each of the 37 land cover types used in this Plan is discussed in one of the natural communities, as shown in the hierarchy in **Table 3-1**. When data are available, vegetation associations are also described for each land cover type. Vegetation associations are distinct units of plant communities defined by the dominant species of plants that are consistently found on the landscape.

Quantitative data on vegetation and plant diversity is often lacking for regional conservation plans. However, a unique data set is available for the Santa Clara Valley HCP/NCCP. In the spring and summer of 2001 and 2002, botanists and volunteers from the CNPS and the CDFG conducted extensive quantitative sampling of vegetation along the approximately 7,000 acre Coyote Ridge (Evens and San 2004). The purpose of this study was to define and document the range of vegetation associations and plant diversity in the mostly serpentine communities of the ridge. Data from 200 locations were analyzed and grouped into discrete associations using standard cluster analysis and ordination techniques.

A total of 47 vegetation associations were defined and described in detail that support 329 unique species. Four of these associations were newly recognized and 32 of them were identified as provisional because they were based on less than 10 samples. Vegetations associations defined by this important study are summarized in this chapter under the relevant natural community as a way to describe the variety of vegetation associations within each land cover type. It is expected that many of these 47 vegetation associations occur elsewhere in the study area. However, it should be recognized that the relatively small sample area (only 1% of the study area) provides limited information on the vegetation diversity of the study area.

The results of the land cover mapping are summarized in **Table 3-7** and described below for each land cover type. See **Figure 3-10** for the land cover map using all land cover types.

## Grassland

*Grassland* consists of herbaceous vegetation dominated by grasses and forbs. Grassland in the study area is classified into six land cover types.

- California annual grassland.
- Non-serpentine native grassland (not mapped).
- Serpentine bunchgrass grassland.

- Serpentine rock outcrop / barrens.
- Serpentine seep.
- Rock outcrop (non-serpentine).

CDFG considers serpentine bunchgrass grassland a sensitive biotic community (California Department of Fish and Game 2003b). The land cover types serpentine seep, serpentine rock outcrop / barrens, and rock outcrop (non-serpentine) are typically associated with grasslands so are also discussed in this natural community.

## Historical Extent and Composition

Historical records do not provide definitive data on the distribution of native perennial grasslands, but research indicates human use of fire may have had a profound impact on the historic distribution and extent of grasslands. Prior to European settlement, native perennial grasslands in Santa Clara County were likely subject to regular burning by native American people. Keeley (2002) surmises that because dense scrub or chaparral had little value to native Americans, they used periodic burning to clear shrubs and provide habitat for fire-tolerant native grasses. Keeley (2002) also implies that the current mosaic of grassland is likely a result of historic vegetation management that favored open grasslands over chaparral.

Another human-made change to the landscape was initiated with the introduction and spread of many nonnative plants throughout California. The invasions began in 1769, when the first Spanish settlements were established at Monterey and San Diego, or possibly earlier. These introductions occurred by unassisted migration or by transport in the belongings or livestock of travelers from the Spanish settlements outside of California or in ship's cargo of coastal explorers. These non-native plant invaders included very aggressive annual grasses and forbs from the grasslands of the Mediterranean region that quickly replaced the natives, both with and without the influence of livestock grazing (Hendry 1931; Blumler 1992; Bartolome et al. 2007). The grazing of livestock in the study area by European settlers became more widespread after the gold rush of the 1850s. The combination of livestock grazing, drought, and spread of aggressive grasses and herbs dramatically reduced the abundance of native grasses and the extent of native grasslands throughout California (Bartolome et al. 2007). Grazing by livestock and wildlife continues today in almost all of the grasslands and other natural communities linked to grasslands (woodlands, riparian woodlands, and shrublands) of the County, although less intensively than in the past. While most grasslands in the County are now dominated by nonnative annuals, small patches of native grasses, below the resolution of the land cover map in this Plan, are found in many of these grasslands. There is some controversy over whether perennial grasses ever dominated California grasslands. It is likely that the Spanish mostly encountered annual grasslands that had a small representation of perennial species intermixed (Blumler 1992).

Further, recent scientific research suggests many of California's modern grasslands were not "grasslands," but might have been dominated instead by shrubs or annual forbs during the Native American period before arrival of the settlers and most of the invading non-native grasses (Hopkinson and Huntsinger 2005; D'Antonio et al. 2007). Schiffman (2007) suggests that drier valley and interior Coast Range "grassland" habitats were dominated by forbs during prehistoric times. Thus, without further study, we cannot be certain of the locations or extents of prehistoric grasslands in the County.

## Common Wildlife Associations

Characteristic wildlife species in grasslands include reptiles such as western fence lizard (*Sceloporus occidentalis*), common garter snake (*Thamnophis sirtalis*), and western rattlesnake (*Crotalis viridis*); mammals such as black-tailed jackrabbit (*Lepus californicus*), California ground squirrel (*Spermophilus beecheyi*), Botta's pocket gopher (*Thomomys bottae*), western harvest mouse (*Reithrodontomys megalotis*), California vole (*Microtus californicus*), American badger (*Taxidea taxus*), and coyote (*Canis latrans*); and birds such as burrowing owl (*Athene cunicularia*), short-eared owl (*Asio flammeus*), horned lark (*Eremophila alpestris*), and western meadowlark (*Sturnella neglecta*). Annual grassland also provides important foraging habitat for turkey vulture (*Cathartes aura*), northern harrier (*Circus cyaneus*), American kestrel (*Falco sparverius*), white-tailed kite (*Elanus leucurus*), and red-tailed hawk (*Buteo jamaicensis*).

Grassland-associated wildlife species covered under this Plan that are known to occur in the study area include San Joaquin kit fox (*Vulpes macrotis mutica*), western burrowing owl (*Athene cunicularia hypugae*), California red-legged frog (*Rana draytonii*), California tiger salamander (*Ambystoma californiense*), western pond turtle (*Clemmys marmorata*), and tricolored blackbird (*Agelaius tricolor*) (**Table 3-5**). California red-legged frog and California tiger salamander breed in aquatic habitats (e.g., ponds) within grasslands, and use grasslands as movement and aestivation (summer hibernation) habitat. Western pond turtle use grassland land cover adjacent to aquatic habitat as year-round and movement habitat. Serpentine grassland provides valuable habitat in the study area for all life stages of the federally threatened Bay checkerspot butterfly (*Euphydryas editha bayensis*) (see the species account in **Appendix D** for more information). The butterfly also uses grasslands as movement corridors between isolated serpentine grassland patches. These grasslands also provide unique habitat for a variety of special-status invertebrates that are not covered by this plan, including several butterfly species and Horn's microblind harvestman (*Microcina homi*).

## Grassland Land Cover Types

Within the Plan study area, California annual grassland was identified by its smooth, pale signature on aerial photograph, lacking the dark green signatures of woody plants taken during the summer months. Native grasslands could not be distinguished reliably on the available imagery.

### California Annual Grassland

*Annual grassland* or *nonnative grassland* is an herbaceous plant community dominated by nonnative annual grasses (Holland 1986; Sawyer and Keeler-Wolf 1995). In the study area, annual grassland was mapped where grasses and forbs dominate the land cover and where trees and shrubs comprise less than 10% canopy cover. The dominant grasses in the study area generally consist of introduced annual grasses from the Mediterranean basin, including wild oats (*Avena barbata* and *A. fatua*), soft brome (*Bromus hordeaceus*), foxtail chess (*B. madritensis*), leporinum barley (*Hordeum murinum* ssp. *leporinum*), Italian ryegrass (*Festuca perennis* [*Lolium multiflorum*]), barbed goatgrass (*Aegilops triuncialis*), harding grass (*Phalaris aquatica*), shiver grass (*Aira caryophyllaea*), rat-tail fescue (*Festuca* [*Vulpia*] *myuros*), ripgut brome (*Bromus diandrus*), nit grass (*Gastridium phleoides* [*G. ventricosum*]), bentgrass (*Polypogon* [*Agrostis*] *viridis*), and small fescue (*Festuca* [*Vulpia*] *microstachys*) (Evens and San 2004). The associated herbaceous cover includes native and nonnative forbs. Common species in the study area include many clover species (*Trifolium* spp.), filaree species (*Erodium* spp.), lupine species (*Lupinus* spp.), four-spot (*Clarkia purpurea* ssp. *quadrivulnera*), California poppy (*Eschscholzia californica*), purple owl's-clover (*Castilleja exserta*), Ithuriel's spear (*Triteleia laxa*), black mustard (*Brassica nigra*), starthistle species (*Centaurea* spp.), wavyleaf soap plant (*Chlorogalum pomeridianum*), common yarrow (*Achillea millefolium*), and common fiddleneck (*Amsinckia menziesii*).

California annual grassland occupies an estimated 81,795 acres (18%) of the study area (Table 3-7 and Figure 3-10). This land cover type is generally found in valley bottoms. In the study area, it is found at low elevations along the eastern side of the Santa Clara Valley bordering the foothills, and on ridges on dry south- and west-facing slopes. Annual grassland is also common on both sides of the Pacheco Pass in the southern portion of the County. It is often found intermingling with oak woodlands and chaparral/scrub communities.

One covered plant that may be found on this land cover type is fragrant fritillary (*Fritillaria liliacea*). This species is restricted to specific habitat elements and micro-site characteristics within California annual grassland.

### Native Grassland (Non-Serpentine)

Native, *non-serpentine grasslands* are patchily distributed in the study area and generally occur as small patches within the larger annual grassland complex. Accordingly, *native grassland* contains an abundance of nonnative annual grasses mixed with perennial grasses and forbs. Native grassland could not be distinguished from annual grassland on aerial photographs of the study area. Consequently, this land cover type was mapped as annual grassland.

Soils which support populations of native non-serpentine grasslands tend to be deep (50–100 cm), high in clay content with few rocks, and mostly on north- and east-facing slopes (Keeley 1993). There are several types of native grasses present in the study area, including purple needlegrass (*Stipa* [*Nassella*] *pulchra*), big squirreltail (*Elymus multisetus*), Torrey's melicgrass (*Melica torreyana*), creeping ryegrass (*Elymus* [*Leymus*] *triticoides*), small fescue, small-flowered needlegrass (*Stipa* [*Nassella*] *lepida*), one-sided bluegrass (*Poa secunda*), blue

wildrye (*Elymus glaucus*), and California melica (*Melica californica*). Native, non-serpentine grasslands in the study area are characterized by the following grassland associations based on quantitative vegetation sampling conducted by the CNPS along extensive areas of Coyote Ridge (Evens and San 2004).

- **Italian ryegrass-purple needlegrass-Gambel's dwarf milkvetch-shining pepperweed (*Lepidium nitidum*) grassland association.** This association can be found on both serpentine and non-serpentine soils but typically occurs in herbaceous stands that have deep soils with high clay content (Evens and San 2004). Plants characteristic of this community are Italian ryegrass, purple needlegrass, hayfield tarweed (*Hemizonia congesta* ssp. *luzulifolia*), beaked cryptantha (*Cryptantha flaccida*), Douglas' microseris (*Microseris douglasii*), blue dicks (*Dichelostemma capitatum*), dwarf plantain (*Plantago erecta*), California poppy, Gambel's dwarf milkvetch, calf lotus (*Acmispon [Lotus] wrangelianus*) and reticulate seeded spurge (*Euphorbia spathulata*).
- **Italian ryegrass-purple needlegrass-coast range false bindweed grassland association.** This association can be found on both serpentine and non-serpentine soils but typically occurs in herbaceous stands that have deep soils with high clay content (Evens and San 2004). Plants characteristic of this community are Italian ryegrass, purple needlegrass, dwarf plantain, coast range false bindweed (*Calystegia collina*), California poppy, and common yarrow.
- **Creeping ryegrass-Italian ryegrass grassland association.** This association is found in the study area in both serpentine and non-serpentine soils of marine origin that experience seasonal flooding (Evens and San 2004). Characteristic species are creeping ryegrass, Italian ryegrass, common fiddleneck, wild oat, soft brome, reticulate seeded spurge, prickly lettuce (*Lactuca serriola*), and California blue-eyed grass (*Sisyrinchium bellum*).
- **Torrey's melicgrass grassland association.** This association is found on both non-serpentine and serpentine soils. Common species are Torrey's melicgrass, Italian ryegrass, soft brome, common yarrow, coast range false bindweed, shooting star species (*Dodecatheon* sp.), naked wild buckwheat (*Eriogonum nudum*), California poppy, and small fescue.
- **Big squirreltail (*Elymus multisetus*)-dwarf plantain-Italian ryegrass association.** Big squirreltail grassland is generally found on sedimentary and serpentine soils. Characteristic species are big squirreltail grass, Italian ryegrass, purple needlegrass, pine bluegrass, soft brome, California poppy, beaked cryptantha, dwarf plantain, California goldfields (*Lasthenia californica*), common yarrow, and wavyleaf soap plant.
- **Small fescue-dwarf plantain grassland association.** Small fescue grassland is typically found on well-developed soils on serpentine and on sedimentary soils that are mesic in spring. Common species are small fescue, common yarrow, soft brome, naked wild buckwheat, California poppy, Italian ryegrass, dwarf plantain, wavyleaf soap plant, Italian ryegrass, and common California-aster (*Corethrogyne [Lessingia] filaginifolia*).

The extent of non-serpentine native grassland in the study area is unknown.

No covered plants may be found on this land cover type.

### **Serpentine Bunchgrass Grassland**

*Serpentine bunchgrass grassland* occurs on ultramafic soils derived from serpentinite. Serpentine soils generally have lower overall cover of vegetation as well as lower cover of nonnative species than annual grasslands, and are characterized by low plant growth and productivity (McNaughton 1968; Holland 1986). This is due in large part to the high content of heavy metals in the soil such as chromium, nickel, and cobalt which are toxic to most plants, very low calcium/magnesium ratios, unusually high levels of iron, and limiting levels of nitrogen, phosphorous, potassium, and calcium, all of which are important plant nutrients (Kruckeberg 1984). Many serpentine species are partially or completely confined to growing on this substrate (Safford et al. 2005). Native bunchgrasses in serpentine habitat are generally similar to those in non-serpentine habitats, although serpentine populations may be more tolerant of heavy metals present in the soil and may have lower growth rates compared to non-serpentine populations (Huntsinger et al. 1996).

Serpentine bunchgrasses typically occur in patches of both single and multiple species (McCarten 1987). As noted above, nonnative annuals are much less dominant in serpentine areas, although increasing nitrogen deposition from air pollution has increased the productivity of serpentine soils and allowed a greater number of nonnatives to invade (Evens and San 2004; Harrison et al. 2003; Weiss 1999). Native grasses typically found on serpentine soils in the study area include big squirreltail, creeping ryegrass, purple needlegrass, Torrey's melicgrass, and small fescue. Some common herbaceous species are fringed sidalcea (*Sidalcea diploscypha*), jeweled onion (*Allium serra*), serpentine linanthus (*Leptosiphon* [*Linanthus*] *ambiguus*), and Franciscan wallflower (*Erysimum franciscanum*) (Evens and San 2004).

Although the total coverage of serpentine soils is relatively small state-wide (1.5%), 13% of plant species endemic to California are serpentine endemics (Safford et al. 2005). Many of these occur in the San Francisco Bay area. There are a variety of ultramafic affinities for serpentine species that can vary by geography. For instance, serpentine species can be strict endemics (95% of the time they are found growing on serpentine), strong indicators (about 70% of the time they are found growing on serpentine), and weak indicators (about 60% of the time they are found growing on serpentine). The herbaceous species listed above have serpentine affinities that fall between strict endemic and strong indicator.

Serpentine grasslands in the study area are characterized by the following associations based on quantitative vegetation sampling conducted by CNPS along extensive areas of Coyote Ridge (Evens and San 2004).

- **Italian ryegrass-purple needlegrass-Gambel's dwarf milkvetch-shining pepperweed grassland association.** Plants typical of this association can be found above in native grasslands. Additional species characteristic of this association on serpentine soils are smooth lessingia (*Lessingia micradenia* var. *glabrata*), most beautiful jewel-flower (*Streptanthus albidus* ssp.

*peramoenus*), and Santa Clara Valley dudleya (*Dudleya abramsii* ssp. *setchellii*).

- **Italian ryegrass-purple needlegrass-coast range false bindweed grassland association.** Plants typical of this association can be found above in native grasslands. Additional species characteristic of this association on serpentine soils are smooth lessingia, Mt. Hamilton thistle (*Cirsium fontinale* var. *campylon*), and jeweled onion.
- **Creeping ryegrass-Italian ryegrass grassland association.** Plants typical of this association can be found above in native grasslands. An additional species characteristic of this association on serpentine soils is smooth lessingia.
- **Torrey's melicgrass grassland association.** Plants typical of this association can be found above in native grasslands. Additional species characteristic of this association on serpentine soils are smooth lessingia, jeweled onion, and Santa Clara Valley dudleya.
- **Big squirreltail (*Elymus multisetus*)-dwarf plantain-Italian ryegrass association.** Plants typical of this association can be found above in native grasslands. Additional species characteristic of this association on serpentine soils are jeweled onion and most beautiful jewel-flower. Other occasional associates are Santa Clara Valley dudleya and serpentine linanthus.
- **Small fescue-dwarf plantain grassland association.** Plants typical of this association can be found above in native grasslands. Additional species characteristic of this association on serpentine soils are Franciscan wallflower, jeweled onion, and most beautiful jewel-flower. Fragrant fritillary and serpentine linanthus also occasionally may be present.

Covered plants that may be found in serpentine bunchgrass in the study area include the following: Tiburon Indian paintbrush (*Castilleja affinis* ssp. *neglecta*), coyote ceanothus (*Ceanothus ferrisiae*), fragrant fritillary, Santa Clara Valley dudleya, smooth lessingia, Mt. Hamilton thistle, Metcalf canyon jewel-flower, and most beautiful jewel-flower (Evens and San 2004; California Natural Diversity Database 2008, 2012; also see **Table 3-6**). These species are restricted to specific habitat elements and micro-site characteristics within serpentine bunchgrass grassland.

Certain species not considered serpentine endemics or indicators but commonly found in serpentine soil areas, host or provide nectar for the federally threatened Bay checkerspot butterfly. Such species include dwarf plantain, purple owl's-clover, California goldfields, common muilla (*Muilla maritima*), and lomatium species (*Lomatium* spp.) (Weiss 1999).

Serpentine bunchgrass grassland occupies approximately 10,308 acres (2.2%) of the study area (**Table 3-7** and **Figure 3-10**). This land cover type was mapped where grasslands intersected either serpentine soils or serpentine bedrock (**Figure 3-4**). In the study area, serpentine bunchgrass grassland is found primarily northwest of Anderson Lake along Coyote Ridge and the Silver Creek Hills. Smaller patches of serpentine bunchgrass grassland can be found in the

Santa Theresa Hills, on Communications Hill, Tulare Hill, and west of Morgan Hill.

### **Serpentine Rock Outcrop / Barrens**

*Serpentine rock outcrops* are exposures of serpentine bedrock that typically lack soil and are sparsely vegetated. Serpentine barrens are areas of exposed serpentine soil that support little vegetation. They were identified based on visible rock outcroppings or barren areas on the aerial imagery intersecting with the serpentine rock or serpentine soils layers respectively; there was no minimum mapping unit. Covered plants that may be found on this land cover type include Metcalf canyon jewel-flower, most beautiful jewel-flower, smooth lessingia, and Santa Clara Valley dudleya (California Natural Diversity Database 2008, 2012; California Native Plant Society 2007).

This land cover type is likely underrepresented in the land cover map for the study area (Kruckeberg 1984; Wagner et al. 1991) because these features are difficult to see on aerial photographs, and were difficult to recognize in the field from a distance.

Covered plants that may be found in serpentine rock outcrop/barrens in the study area include the following: Tiburon Indian paintbrush, Santa Clara Valley dudleya, smooth lessingia, Metcalf canyon jewel-flower, and most beautiful jewel-flower (**Table 3-6**). These species are restricted to specific habitat elements and micro-site characteristics within serpentine rock outcrop.

Serpentine rock outcrops occupy an estimated 260 acres (0.05 %) of the study area (**Table 3-7** and **Figure 3-10**). This land cover type is found strictly in areas of serpentine soils or geology. In the study area, serpentine rock outcrops are found in the same locations as serpentine bunchgrass grassland.

### **Serpentine Seep**

*Seeps* are otherwise dry areas where water penetrates the surface and creates a small wetland habitat that supports wetland vegetation. These provide a source of drinking water for wildlife in the area. Serpentine seeps typically occur within a matrix of serpentine grassland so they are discussed in the grassland natural community. Serpentine seep vegetation associations found in the Plan study area are described below (Evens and San 2004).

- **Mt. Hamilton thistle-twotooth sedge (*Carex serratodens*)-meadow barley forbland<sup>14</sup> association.** This association is found exclusively on serpentine seeps. Plants characteristic of this association are Mt. Hamilton thistle, twotooth sedge, meadow barley (*Hordeum brachyantherum*), hayfield tarweed, narrow-leaved wild-lettuce (*Lactuca saligna*), common yarrow, California poppy, Italian ryegrass, meadow barley, irisleaf rush (*Juncus xiphioides*), and seep monkey flower (*Mimulus guttatus*). Additional common species in this association are bentgrass, purple needlegrass, hoary coffeeberry (*Frangula californica* ssp. *tomentella* [*Rhamnus tomentella*]),

<sup>14</sup> A *forb* is another term for an herbaceous plant. A *forbland* is a vegetation association dominated by forbs (similar in concept to a grassland).

rabbit's foot (*Polypogon monspeliensis*), smooth lessingia, and most beautiful jewel-flower.

- **Mt. Hamilton thistle-hayfield tarweed forbland association.** This association is found exclusively on serpentine seeps. Plants characteristic of this association are Mt. Hamilton thistle, hayfield tarweed, irisleaf rush, rabbit's foot, hoary coffeeberry, and smooth lessingia.
- **Mt. Hamilton thistle-seep monkey flower-short-spiked hedge nettle forbland association.** This association is found exclusively on serpentine seeps. Plants characteristic of this association are Mt. Hamilton thistle, sourclover (*Melilotus indicus* [*M. indica*]), seep monkey flower, short-spiked hedge-nettle (*Stachys pycnantha*), yellow star thistle (*Centaurea solstitialis*), soft brome, California poppy, irisleaf rush, Italian ryegrass, common yarrow, California sagebrush (*Artemisia californica*), foxtail chess, Pacific false bindweed (*Calystegia purpurata*), medusa-head (*Elymus* [*Taeniatherum*] *caput-medusae*), and most beautiful jewel-flower.
- **Irisleaf rush herbaceous association.** This association is found exclusively on serpentine seeps. Plants characteristic of this association are irisleaf rush, Italian ryegrass, twotooth sedge, Mt. Hamilton thistle, Baltic rush (*Juncus balticus*), hyssop loosestrife (*Lythrum hyssopifolia*), and rabbit's foot.
- **Leather oak-hoary coffeeberry-bigberry manzanita shrubland.** This association is found in serpentine seeps and in riparian drainages on serpentine. Leather oak (*Quercus durata*) and hoary coffeeberry are co-dominant, followed by bigberry manzanita (*Arctostaphylos glauca*). The shrub layer has sparse to dense coverage (9–70% on Coyote Ridge) of Italian ryegrass, slender wild oat, ripgut brome, hayfield tarweed, seep monkey flower, and Mt. Hamilton thistle are all common in the open herb layer.

One covered plant, Mt. Hamilton thistle, is restricted to serpentine seeps and streams and drainages through serpentine soils (**Table 3-6**). Serpentine seeps were mapped on 34 acres (0.01%) of the study area (**Table 3-7** and **Figure 3-10**).

### Rock Outcrop (Non-Serpentine)

Frequently encountered features in grasslands are *rock outcrops*, which are exposures of bedrock that typically lack soil and have sparse vegetation. Within the study area, several types of rock outcrops are present and are derived from sedimentary, volcanic, and metamorphic sources. Rock outcrops identifiable on aerial photographs were mapped based on their unique aerial photograph signatures. Rock outcrop signatures appear as textured areas with mottled coloring that contrasted in color and texture with the surrounding cover types on aerial photographs. There was no minimum mapping unit.

Rock outcrops host common wildlife species such as western fence lizard and western rattlesnake. These species may use outcrops for basking and as foraging areas. Common birds include rock wren (*Salpinctes obsoletus*) and several species of raptors that use rock outcrops for nesting or roosting. Rock outcrops with crevices or caves could host roosting bats.

Most beautiful jewelflower may be found on non-serpentine rock outcrops (**Table 3-6**).

Rock outcrops are a rare land cover type, totaling 87 acres (0.02%) of the study area (**Table 3-7** and **Figure 3-10**). They are primarily found in annual grasslands although they also can be present in chaparral and oak woodlands. This land cover type is likely underrepresented in the land cover map because these features are difficult to see on aerial photographs, particularly if they were below a chaparral or woodland canopy, and were difficult to recognize in the field from a distance. Accordingly, many small areas of rock outcrops are likely included in the chaparral/scrub, grassland, and oak woodland land cover types.

## Ecosystem Functions

### Function and Integrity

The grassland types within the study area function as a dominant natural community, linking small and large patches of all other natural communities in the landscape such as oak woodland, riparian and aquatic communities, northern mixed chaparral/chamise chaparral, and northern coastal scrub/Diablan sage scrub. Rock outcrops, barrens, and seeps are contained within the larger matrix of grasslands, and in some cases, the functions and threats to the integrity of these land cover types differs from the larger grassland matrix. This section primarily addresses the grassland types. Differences, where relevant, are noted for the small-scale land cover types contained within grasslands.

Grasslands provide critical upland habitat for a variety of amphibians dependent on adjacent aquatic habitats such as ponds and seasonal wetlands. These amphibians move through grasslands during the rainy season to disperse to other aquatic sites, and may reside in moist refuges, such as burrows and piles of litter and debris, within grasslands during the dry season. Grasslands are important for burrowing rodents such as ground squirrels and gophers. Rodent burrows, in turn, provide key habitat for a variety of other species, including burrowing owls. The diverse and abundant rodent community supports an assemblage of raptors that feed on them, including golden eagle (*Aquila chrysaetos*), northern harrier, and white-tailed kite. Serpentine grasslands are important habitat for all life stages of the federally threatened Bay checkerspot butterfly, and a host of other rare species.

Grasslands also help maintain water supplies and water quality through soil moisture retention and infiltration and by filtering out sediment, nutrients, and pathogens from run-off. They provide wildlife habitat, storage of carbon, and forage for grazing livestock. The key characteristics of grassland habitat that contribute to these functions are a high cover of herbaceous vegetation. A mix of woody cover in grassland (mosaic of shrubs or savanna) is also important to resist soil erosion and mass-wasting, and benefits some special-status animals.

The replacement of native grasses and herbs by fast-growing nonnative annual grasses and herbs has had a profound effect upon ecosystem functions in grasslands. The complex system of native grasses, forbs, shrubs, and animals of

grassland habitats, plus the effects of lightning-caused wildfire and Native American management during prehistoric times has been dramatically altered. For example, the exotic annuals germinate and grow faster and can deplete soil moisture and reduce light and nutrient availability to the natives. However, seed limitation due to low production or small populations may also limit native grass establishment. Both native and non-native shrubs and trees can invade California grasslands, causing changes in fire fuel structure, carbon storage, animal habitat, and facilitation of the establishment of other woody plants. The exotic grasses and forbs have a larger and more persistent seed bank than the natives, and distribute seeds abundantly as seed rain. The exotic species can thus rapidly colonize disturbance areas, such as gopher mounds, and inhibit establishment of the native species. Grazing livestock are likely to be important dispersal agents for the exotic plants, but grazing intensity has not been linked by scientific evidence to current invasions of exotic plants into California grasslands (Jackson and Bartolome 2007).

The widespread occurrence of non-native species has altered the response of California grasslands to burning. Increased fuel loading around trees and native grasses can result in reduced survival of the native grasses. Non-native grasses are favored where atmospheric nitrogen deposition has increased or where nitrogen-fixing shrubs, such as brooms (*Genista* spp. or *Cytisus* spp.) have invaded and elevated soil nitrogen. Serpentine soils are particularly vulnerable to such means of invasion. Phenology of the converted grassland is dramatically different from that of the prehistoric native grasslands. The exotic annual grasses germinate and grow in synchrony with the rains of fall through spring, while the native perennial grasses extend their growth and transpiration of soil moisture into the summer months. The roots of the exotic annual grasses are generally less deep than those of the native perennial grasses, which can tap deeper soil moisture. The absence of perennial grasses in the converted grasslands can lead to reservoirs of deep soil moisture during the summer, which may be accessed by deep-rooted pest plants, such as yellow starthistle. Different microbial compositions have been found in the soils of California grasslands and planted containers with exotic annual versus native perennial grasses, but less is known about nutrient feedbacks and effects on soil structure. In a few cases, pathogens of grassland plants also appear to facilitate dominance of the exotic species.

### **Natural Disturbance**

The key natural disturbances that have shaped and continue to influence grassland composition and extent are fire and grazing. **Figure 3-11** shows areas currently grazed in the study area. Both of these disturbances are now largely controlled by humans. Therefore, by extension, the continuing introductions and naturalization of aggressive non-native plants should also be considered an important factor influencing grasslands, and one also largely controlled by humans (Randall and Hoshovsky 2000). Nitrogen deposition into grasslands near air pollution sources and the resultant increase in productivity of the soils that has facilitated the increased invasion by nonnative species is a relatively recent anthropogenic disturbance. The disturbances related to nitrogen deposition and non-native plant introductions are discussed further under *Threats* below.

Periodic fire is an important influence on the grassland community. Historically and prehistorically, fires from both lightning strikes and human ignition kept woody vegetation from invading grassland (where the soil conditions are appropriate) and converting it to coastal scrub or oak woodland. Grassland was likely the dominant vegetation community, especially near prehistoric and historic settlements and travel routes, and in association with brush clearing for “rangeland improvements” to increase livestock forage (Reiner 2007; Tyler, Odion, and Callaway 2007). The prehistoric burning apparently resulted in spatially patchy grasslands in a mosaic with woody vegetation (Keeley 2002). The grasslands were kept open by fire, drought, and possibly some influence of native grazers, such as tule elk and pronghorn. However, prior to Native American occupancy and their frequent burning, Ford and Hayes (2007) speculate that many of the grasslands within the range of coyotebrush would have been brushlands. Today, in the absence of frequent extensive fire and moderate or higher intensity livestock grazing, the grasslands within the range of coyotebrush have succeeded or will succeed in the future to northern coastal scrub and eventually mixed woodland, except on the hottest south-facing slopes and shallow soils.

Prescribed burning is considered an important management tool in grasslands and other natural communities, but it has significant practical limitations. Such burning is becoming increasingly difficult to implement due to cost, safety concerns from expanding urban and rural development, and difficulty obtaining permits because of air quality concerns. It has not been feasible in most places to burn frequently enough to control the spread of woody species into existing grassland, or to reduce the cover of woody vegetation within grasslands, because of the natural resistance and resilience of the woody plants to a single burn (Ford and Hayes 2007). Attempts to restore pre-historic or historic fire regimes in grasslands in order to increase native grassland plants is not recommended due to uncertainties of the prehistoric grassland characteristics and the risk of facilitating invasions by non-native plants (Reiner 2007). However, livestock grazing has continued on most rangelands of the study area (see **Figure 3-11**) since introduction by the Spanish settlers, and its effects on both fire hazard reduction and shrub invasion are understood and can be prescribed (Ford and Hayes 2007). While early livestock grazing practices are acknowledged to have been excessive and damaging to grasslands and associated resources in some places, they are far less so today. In fact, livestock grazing in the region is regarded as generally beneficial and has maintained suitable habitat conditions for many special-status grassland-dependent species since the conversion from native species to exotic annuals in the grasslands in the 18th century or earlier.

Grassland is considered a fire-tolerant community. The direct effect of fire on grassland is to remove much or nearly all of the aboveground herbaceous biomass, depending on fire severity. Often the low-intensity prescribed fire moves so quickly and the residue (or thatch) is moist enough that the fire burns only above the lower few centimeters of material, leaving much unburned or only charred on the ground. Fires in grassland are described as *stand-replacing fires*. However, the immediate effect of this biomass removal on annual grasses is negligible, as they have typically completed their growth cycle before fires occur (Howard 1998). Their seeds are typically well dispersed, and many can be

protected by the cover of litter and in cracks in the soil surface over which a fire passes. Perennial bunchgrasses suffer a temporary loss of foliage, but typically regenerate immediately through tillering and regrowth of green foliage that typically remains in the center of grass tussocks (Steinberg 2002).

The immediate effect of a fire in grasslands is typically an increase in annual forb germination and flowering and an increase in overall productivity in response to the light and nutrients made available by the removal of the thatch layer during the following growing season (Harrison et al. 2003). In the two to three years following a fire, the elimination of the thatch layer (if present) may shift the species composition of grasslands towards annual forbs and small-seeded species such as purple needlegrass and little quaking grass (*Briza minor*) (Howard 1998; Steinberg 2002). In the absence of grazing, however, a thatch layer can re-establish (depending on favorable weather), and this effect will disappear. Burning appears to have little long-term effect on annual grassland (Heady 1988; Paysen et al. 2000; Kyser and Di Tomaso 2002). In grasslands that are already dominated by nonnative annual grasses, nonnatives may increase their dominance following fire by outcompeting natives for the newly available space and light. Native grasses may increase their dominance in serpentine grasslands following fire through the same mechanism (Harrison et al. 2003).

Livestock grazing within grasslands is an important disturbance that mimics some of the functions of fires and of native herbivores that are no longer present (e.g., Tule elk, pronghorn). Livestock grazing is also an important management tool to combat relatively new threats such as loss of suitable habitat for special-status species due to dense growth during wet years and invasions of woody plants (Ford and Hayes 2007), and increased invasive nonnative plants in serpentine grasslands due to atmospheric nitrogen deposition (Weiss 1999). The primary drivers of annual grassland composition are the environmental conditions of each site, including soils and annual weather. Bartolome (2011) has estimated that annual weather fluctuations cause about 80% of the shifts in composition of California annual grasslands. Management, including grazing systems, therefore has a limited influence. As a result, studies of grazing effects on native species populations have mixed results, and must be interpreted carefully.

Properly timed grazing can be used to suppress non-native herbaceous competition with native plants, and may favor native grasses and wildflowers. The density and vigor of native perennial grasses can be improved when intensive spring grazing is curtailed just before the existing native perennial grasses re-grow, flower, and set seed (Menke 1992). This specialized grazing removes much of the density and mass of the non-native annual grasses through their growing season, which is shorter than for the native perennial grasses. Curtailing grazing at that time simultaneously allows the native perennial grasses to grow, flower, and set seed before the soil moisture is exhausted. Other research has shown mixed results, and suggests caution in grazing prescriptions to favor native grasses. A study at Jepson Prairie by Dyer, Fossum, and Menke (1996) found that grazing was not effective to increase purple needlegrass and that climate is the more influential factor. Hatch et al. (1999) suggest that different native grasses and forbs have different and sometimes conflicting

responses to management, and therefore more research is needed to guide grazing and burning practices. In a study of coastal prairie, Hayes and Holl (2003) found that native grasses were not more abundant where grazed than where ungrazed. However they found native forbs were more abundant where grazed due the suppression of non-native herbaceous competition and build-up of thatch. Spring and summer wildflowers of grasslands are typically more showy where grazing has occurred (Edwards 1992). Furthermore, Hayes and Holl (2011) found that stands of native grasses are slow to respond to treatments, and fluctuated in response to multiple factors other than management, including annual weather patterns; and that grazing, even when controlled with specific frequencies, holds little promise for increasing native species over the long term.

Grazing may have little effect on species diversity in serpentine grasslands (Harrison 1999). In one case in Santa Clara County reported by McCarten (1987), grazing was associated with a decrease in native bunchgrass species compared to recently ungrazed sites, but that could have been related to non-grazing management or microhabitat differences. Because invasive nonnatives are generally not tolerant of serpentine soils, these species are less invasive in serpentine bunchgrass grasslands than in non-serpentine grasslands (Harrison 1999). Studies in Bay checkerspot butterfly habitat have found that livestock grazing is necessary to prevent nonnative species from becoming dominant, and promote the establishment and persistence of nectar species preferred by the Bay checkerspot butterfly (Harrison 1999; Weiss 1999; Weiss and Wright 2005, 2006; Weiss, Wright, and Niederer 2007). Harrison and Viers (2007) caution that the known invasions of non-natives into serpentine grasslands can be partly a result of slower rates of spread, and that factors other than nitrogen deposition could undermine the resistance of these grasslands, including evolution of serpentine-tolerance in existing non-natives, arrival of new serpentine tolerant non-natives (notably goatgrass [*Aegilops cylindrica*] and medusa-head), and modification of the soils to favor more invasions. They also caution that livestock grazing and infrequency of fire in serpentine grasslands can contribute to declines in native species.

In general, livestock grazing has been associated with benefits to serpentine grasslands (Harrison and Viers 2007). Reported studies indicate that removal of grazing had either no effect on plant species composition or the abundance of native forbs decreased, while grazing increased diversity of native annual forbs. Low-statured native annual forbs are expected to benefit from moderate grazing by reducing the thatch produced by the non-native annual grasses.

Grazing might have a negative effect on the physical structure and native seed banks of serpentine seeps, serpentine rock outcrops, and serpentine barrens that are contained within the larger grassland matrix, but no scientific research has been published on this topic. These small land cover types might be somewhat sensitive to cattle traffic. Most seep soils are moist or saturated for most or all of the year, while rock outcrop/barrens usually have low plant cover and minimal soil and seed bank accumulations. Depending on intensity and frequency of grazing traffic, this can be a long-term effect that is very difficult to restore. Fencing can be used to eliminate or minimize access by livestock to sensitive serpentine seeps, rock outcrops, or barrens.

### Threats

The primary known threats to conservation of California grasslands are: climate change; human development (habitat destruction and fragmentation); invasive species (pathogens, plants, animals); altered disturbance regimes; and air pollution.

The conservation threats associated with human development, including habitat destruction and fragmentation due to conversion of natural grasslands to residential and commercial development, conversion to cultivated agriculture, road construction, and the patterns of such development across the landscape, are the subjects of this Habitat Plan, and are discussed in other chapters.

The threats to conservation of grasslands posed by continuing invasions and infestations of aggressive non-native plants have been described above. In general, and perhaps most significantly, the non-native grasses and forbs of modern grasslands now pose the threat of significant habitat degradation if not grazed by livestock or otherwise treated to maintain suitable habitat structure and reduce competition.

Atmospheric nitrogen enrichment fosters the invasion of nonnative species, which replace native species. This is a threat in all grasslands downwind of air pollution sources, but particularly in serpentine grasslands, where the nectar plant hosts to the bay checkerspot butterfly are affected (Weiss 1999). Absence of grazing thus threatens the butterfly populations. In Santa Teresa County Park and other locations, several populations of Bay checkerspot butterfly declined substantially after grazing was halted. Once grazing ceased, the numerous non-native grasses and forbs present in the serpentine grasslands grew tall and dense each year, and through competition reduced the butterfly's host plants (U.S. Fish and Wildlife Service 2001). The USFWS recognizes activities that threaten the butterfly's critical habitat, include ground disturbance, removing vegetation, altering or removing grazing practices, application of pesticides and biological agents, and some recreational activities. In the case of Santa Teresa County Park, the USFWS recognized that re-introduction of grazing would be needed to ensure recolonization of the butterfly.

In addition, introduced pathogens can indirectly facilitate the invasions of non-native plants, reduce savanna and woodland canopies and thus expand grasslands, and reduce populations of key native grassland birds and rodents (D'Antonio et al. 2007). The threats to conservation of grasslands posed by altered disturbance regimes due to fire and grazing have been discussed above. Studies have demonstrated that well-managed livestock grazing within grasslands is critical to maintain populations of Bay checkerspot butterfly (Harrison et al. 2003; Weiss and Wright 2005, 2006; Santa Clara Valley Transportation Authority 2006). However, as noted above, grazing might be detrimental to serpentine seeps and most rock outcrop/barrens. The threat of reduction or elimination of grazing as a habitat management has also been discussed above.

Serpentine seeps are a type of wetland and many of the threats discussed in the wetland section below are applicable to seeps within grasslands. In particular, alteration of hydrologic regimes by adjacent land uses and development can

change and in some case remove the water source for these seeps. This can result in partial or complete loss of seep wetlands.

Other threats to grasslands include feral pigs, power lines, off-road vehicle activity, improper burning regimes, and road and trail construction (Evens and San 2004).

## Chaparral and Northern Coastal Scrub

*Chaparral shrub communities* are found throughout California on rocky, porous, nutrient-deficient soils and on steep slopes up to 2000 m in elevation (Keeley 2000). These communities are dominated by densely packed and nearly impenetrable drought-adapted evergreen woody shrubs, 1.5–4 meters tall, that possess small, thick, leathery sclerophyllous leaves (Hanes 1988; Keeley 2000). Herbaceous and arboreal growth forms are often lacking or play minor roles in this community (Keeley 2000). Chaparral species have both deep and shallow roots that allow them to tap water in several soil layers (Schoenherr 1992). The deep roots also allow chaparral to tolerate summer drought conditions and stay active during this period of water stress. Chaparral is divided into two land cover types for this Plan.

- Northern mixed chaparral/chamise chaparral.
- Mixed serpentine chaparral.

CDFG considers the latter a sensitive biotic community (California Department of Fish and Game 2007). *Northern coastal scrub*, in comparison, is generally characterized by low shrubs, usually 0.5–2 meters tall with soft non-sclerophyllous leaves, interspersed with grassy openings (Holland 1986). Although coastal scrub is found in both northern and southern California, the form and variety of species varies greatly between the two regions. Coastal sage scrub in southern California is characterized by drought-deciduous shrubs that lose their leaves with the onset of arid summer conditions. In southern California this community lacks a significant herb layer. Northern coastal scrub is characterized by the absence of drought-deciduous shrubs and the presence of an herb-rich community, which is likely a result of plentiful annual rainfall and regular summer fog (Heady et al. 1988; California Partners in Flight 2004). Northern coastal scrub is also less diverse floristically than coastal sage scrub and shrubs are generally taller and more densely spaced (California Partners in Flight 2004). The range of this northern community can be defined as a narrow coastal strip from southern Oregon to Pt. Sur in Monterey County (Holland 1986; Heady et al. 1988). Northern coastal scrub in this study was divided into two land cover types.

- Northern coastal scrub/Diablan coastal scrub.
- Coyote brush scrub.

## Historical Extent and Composition

Native Americans frequently burned shrublands to encourage grass and forb development as dense scrub or chaparral had little value to them (Keeley 2002). A fire-return interval of more than once or twice per decade is detrimental to non-sprouting shrubs such as most *Ceanothus* and *Arctostaphylos* species and tends to promote the reduction of shrublands in favor of grasslands (Keeley 2002). With the Spanish and Mexican settlement, most of the burning by native Americans stopped and fire frequency declined (Greenlee and Langenheim 1990); however, ranchers still burned chaparral areas to expand the prairie for pasture (Greenlee and Langenheim 1990). With the influx of people from the Gold Rush of 1849, rangelands became crowded and settlers increased the conversion of shrublands to nonnative grasslands (Keeley 2004). The historic extent and composition of shrublands in the study area is unknown. However, the fact that chaparral and shrublands are so common today suggests that the study area may not have seen the type conversion of chaparral to grassland experienced in other parts of California.

## Common Wildlife Associations

Common wildlife species that use chaparral and scrub habitats in the study area include gopher snake (*Pituophis melanoleucus*), western rattlesnake, western fence lizard, brush rabbit (*Sylvilagus bachmani*), California pocket mouse (*Perognathus californicus*), Botta's pocket gopher, California ground squirrel, spotted skunk (*Spilogale gracilis*), mule deer, coyote, and bobcat (*Lynx rufus*). Common bird species include mourning dove (*Zenaida macroura*), California quail (*Callipepla californica*), Anna's hummingbird (*Calypte anna*), western scrub-jay, Bewick's wren (*Thryomanes bewickii*), California towhee (*Pipilo crissalis*), lesser goldfinch (*Carduelis psaltria*), fox sparrow (*Passerella iliaca*), white-crowned sparrow (*Zonotrichia leucophrys*), and dark-eyed junco (*Junco hyemalis*).

## Chaparral and Northern Coastal Scrub Land Cover Types

### Northern Mixed Chaparral/Chamise Chaparral

*Northern mixed chaparral/chamise chaparral* is classified by Holland (1986) as "broad-leaved sclerophyll shrubs, 2–4m tall, forming dense, often nearly impenetrable vegetation...[with] usually little or no understory vegetation [and] often considerable accumulation of leaf litter." Northern mixed chaparral/chamise chaparral appeared darker green in color than other chaparral types in all seasons, and frequently occupied larger areas. Chamise chaparral was originally split into a separate land cover type but could not be distinguished on the aerial photograph from northern mixed chaparral.

Dominant shrubs in this community in the study area are chamise (*Adenostoma fasciculatum*), manzanita (*Arctostaphylos* spp.), scrub oak (*Quercus berberidifolia*), and ceanothus (*Ceanothus* spp.). Other important species are

toyon (*Heteromeles arbutifolia*), coffeeberry (*Frangula [Rhamnus] californica*), madrone (*Arbutus menziesii*), California bay (*Umbellularia californica*), birchleaf mountain-mahogany (*Cercocarpus betuloides*), poison-oak (*Toxicodendron diversilobum*), bush monkey flower (*Mimulus aurantiacus*), and California yerba santa (*Eriodictyon californicum*). Some chaparral stands may be almost entirely composed of dense stands of chamise (Holland 1986). Northern mixed chaparral/chamise chaparral in the study area includes the following shrubland associations based on quantitative vegetation sampling conducted by the CNPS along extensive areas of Coyote Ridge (Evens and San 2004):

- **Chamise (pure) shrubland association.** Chamise is the dominant species in this association of dense shrubs<sup>15</sup> that generally occurs on extremely dry sites on south-facing, moderately steep to steep slopes. The herbaceous component is minor and sometimes absent in this association. Additional species which may have sparse representation are black sage (*Salvia mellifera*), coast live oak (*Quercus agrifolia*), wild mustard (*Hirschfeldia incana*), toyon, California cudweed (*Pseudognaphalium [Gnaphalium] californicum*), Napa star thistle (*Centaurea melitensis*), coyote brush (*Baccharis pilularis*), buck brush (*Ceanothus cuneatus*), California yerba santa, and silk tassel species (*Garrya* spp.).
- **Chamise-bigberry manzanita-bush monkey flower shrubland association.** This association of open to dense shrubs can be found on both serpentine and non-serpentine soils. The understory herbaceous layer is a small component of the community and is relatively open. The dominant shrubs are chamise and bigberry manzanita. Bush monkey flower and redberry buckthorn (*Rhamnus crocea*) are present in this shrubland. Other species that sometimes are present in this association are Torrey's melicgrass, California sagebrush, woolly-fruited lomatium (*Lomatium dasycarpum*), chaparral silk tassel (*Garrya congdonii*), hounds tongue (*Cynoglossum grande*), wavyleaf soap plant, coyote brush, scarlet pimpernel (*Anagallis arvensis*), and shiver grass.
- **Chamise-black sage (pure) shrubland association.** This association features chamise and black sage as co-dominants on south-facing slopes. Bigberry manzanita is present with lower coverage. There may also be a small open hardwood overstory component and herbaceous layer. Other species which may be present but sparse are slender wild oats, lichen, small-flowered needlegrass, California sagebrush, ceanothus species and coast live oak.
- **Bigberry manzanita-mixed (California sagebrush-black sage) shrubland association.** This mixed shrubland is found on serpentine and non-serpentine soils. Bigberry manzanita is dominant in a layer of somewhat openly spaced to more densely packed shrubs. There is an herbaceous understory layer and a small tree layer comprising conifers and hardwoods. Additional shrubs that may be found are California sagebrush, black sage, and less frequently chamise. Grasses commonly present are small-flowered

<sup>15</sup> On Coyote Ridge, chamise has an absolute cover of 50–60% (Evens and San 2004).

needlegrass, foxtail chess, slender wild oats, and Italian ryegrass. Coast live oak and foothill pine (*Pinus sabiniana*) may be present in the overstory.

- **Coyote brush/annual grass shrubland association.** This association consists of coyote brush, which is dominant in an open canopy, and a continuous herbaceous understory composed primarily of grasses with wild oats as the dominant. Additional grasses include ripgut brome, soft chess, Italian ryegrass, foxtail chess, and purple needlegrass. Other herbaceous elements include turkey mullein (*Croton [Eremocarpus] setigerus*), yellow star thistle, common yarrow, bull thistle (*Cirsium vulgare*), Kellogg's yampah (*Perideridia kelloggii*), California cudweed, gumweed (*Grindelia* spp.), hayfield tarweed, wild mustard, and wavyleaf soap plant.
- **Coyote brush-California sagebrush-toyon shrubland association.** This association occurs both on serpentine and non-serpentine soils generally on southeast- to southwest-facing slopes. The shrub layer can be more openly spaced or have denser coverage (30–80% on Coyote Ridge) and has an open herbaceous understory layer. Coyote brush is the dominant shrub, with toyon, California sagebrush, and bush monkey flower as associates. Other characteristic species are moss and California cudweed. Also frequently present are lichen, foxtail chess, and California figwort (*Scrophularia californica*). Black sage, deerweed (*Acmispon glaber [Lotus scoparius]*), and nit grass are less frequently encountered in this association.
- **Birchleaf mountain mahogany-chamise-bush monkey flower association.** This is a mixed shrub association with open cover (30% on Coyote Ridge). Birchleaf mountain mahogany, chamise, and bush monkey flower are dominants. The herbaceous layer is open and is composed primarily of Torrey's melic grass. An open hardwood layer may also be present. Other species that may be present in small numbers are hollyleaf cherry (*Prunus ilicifolia*), poison-oak, bedstraw (*Galium* spp.), sticky cinquefoil (*Drymocallis [Potentilla] glandulosa*), goldenback fern (*Pentagramma triangularis*), common yarrow, nit grass, purple sanicle (*Sanicula bipinnatifida*), foxtail chess, shiver grass, and Spanish broom (*Spartium junceum*).

Northern mixed chaparral/chamise chaparral occupies an estimated 23,763 acres (5.2%) of the study area (**Table 3-7** and **Figure 3-10**). This land cover type is found in the northeastern part of the study area in the Western Diablo and Diablo Ranges (**Figure 3-10**). It is also found in the central western portion of the study area. Northern mixed chaparral may intermingle with northern coastal scrub/Diablan sage scrub, foothill pine and oak woodlands, and mixed oak woodland and forest.

The covered plant that may be found on this land cover type is Loma Prieta hoita (*Hoita strobilina*), which grows in loose talus in chaparral (**Table 3-6**). Several wildlife species may be found in this land cover type as well. Given the presence of adjacent aquatic habitat, California tiger salamander, California red-legged frog and western pond turtle may use northern mixed chaparral/chamise chaparral as movement, avestation, or foraging habitat (**Table 3-5**).

### Mixed Serpentine Chaparral

*Mixed serpentine chaparral* consists of fire-adapted shrubs found on serpentine soils (California Partners in Flight 2004). Serpentine chaparral is generally more open than other chaparral types and shrubs tend to be shorter and have leaves which are reduced, curled, or thickened (Hanes 1988; California Partners in Flight 2004). Species present in mixed serpentine chaparral with a high affinity for serpentine are coyote ceanothus, *Calistoga navarretia* (*Navarretia heterodoxa*), Santa Clara Valley dudleya, Mt. Hamilton thistle, smooth lessingia, and Tiburon Indian paintbrush (*Castilleja affinis* ssp. *neglecta*).

Mixed serpentine chaparral in the study area includes the following associations based on quantitative vegetation sampling on Coyote Ridge (Evens and San 2004):

- **Bigberry manzanita/Torrey's melic grass shrubland association.** This association is found on serpentine soils with bigberry manzanita as the dominant shrub in an open shrub layer. Species that follow in dominance are Torrey's melic grass and soft brome. Other species that may be present in the understory are foxtail chess, small fescue, Italian ryegrass, slender wild oats, California sagebrush, and leather oak. Less frequently encountered species are purple needlegrass, toyon, rat-tail fescue, dwarf plantain, one-sided bluegrass, and ripgut brome.
- **Hollyleaf cherry-poison-oak/grass shrubland association.** The dominant shrub in this open serpentine shrub association is hollyleaf cherry. Coast live oak and valley oak (*Quercus lobata*) are often present in the overstory. Scrub oak and poison-oak are ubiquitous but in low cover. Other commonly associated shrubs with higher cover are bush monkey flower, bigberry manzanita, and California sagebrush. The most common species in the herbaceous layer, which is scattered to more frequent in coverage, include Italian ryegrass and soft brome. Foxtail chess, slender wild oats, wild mustard, Napa star thistle, phlox-leaved bedstraw (*Galium andrewsii*), Torrey's melic grass, ripgut brome, and common yarrow may also be present.
- **Leather oak-bigberry manzanita-chaparral silktassel/Torrey's melic grass shrubland.** This association occurs on north-facing rocky slopes on serpentine parent material. It has also been documented on talus deposits in the Mt. Hamilton Range. Leather oak is the dominant species in the shrub layer, which tends to be open to more continuously present (30–78% cover on Coyote Ridge). Bigberry manzanita and chaparral silktassel are also characteristic, with the former sometimes occurring as a co-dominant with leather oak. Other shrubs sporadically but frequently present are redberry buckthorn, poison-oak, toyon, hoary coffeeberry, hollyleaf cherry, and birchleaf mountain mohagany. The hardwood overstory tree layer may include scattered coast live oak.
- **Leather oak-bigberry manzanita-coast sagebrush/grass shrubland.** This serpentine shrubland association can be found on all aspects. Leather oak and bigberry manzanita are co-dominants in a shrub layer that is open to more continuously present (12–45%). California sagebrush has the third greatest shrub coverage in the association. In the herb layer, Torrey's melic

grass, slender wild oat, and soft brome are characteristic species. Other grasses and herbs that may be present are Italian ryegrass, ripgut grass, foxtail chess, small-flowered needlegrass, poison-oak, California poppy, scrub oak, and hayfield tarweed. Santa Clara Valley dudleya may occur on rock outcrops within this association.

- **Leather oak-toyon-California bay shrubland association.** This association is found on north-facing slopes on serpentine parent material. The shrub layer is discontinuous to continuous and is dominated by leather oak. Poison-oak, bigberry manzanita, and toyon are subdominant but can be dominant in certain stands. This association is also characterized by an emergent layer of California bay. Additional characteristic shrubs are hoary coffeeberry, birchleaf mountain mahogany, bush monkey flower, California gooseberry (*Ribes californicum*), chaparral mallow (*Malacothamnus fasciculatus*), and blue elderberry (*Sambucus nigra* ssp. *caerulea* [*S. mexicana*]). Torrey's melic grass, soft brome, Italian ryegrass, and reddened clarkia (*Clarkia rubicunda*) are often present in low cover.
- **Hoary coffeeberry-Mt. Hamilton thistle-seep monkey flower shrubland.** This association occurs on northwest- and southwest-facing slopes in wetlands and seeps on serpentine soils. The shrub layer is open to more continuous with hoary coffeeberry as the dominant shrub. Italian ryegrass dominates a semi-continuous herbaceous layer but Mt. Hamilton thistle, seep monkey flower, hayfield tarweed, and common yarrow are also characteristic. Barley species (*Hordeum* spp.), bentgrass, irisleaf rush, and California poppy are frequently encountered as well.

Associations that occur both in serpentine and non-serpentine soils and are described above under *northern mixed chaparral/chamise chaparral* include

- **Chamise-bigberry manzanita-monkey flower shrubland association.**
- **Bigberry manzanita-mixed (California sagebrush-black sage) shrubland association.**
- **Coyote brush-California sagebrush-toyon shrubland association.** Coyote ceanothus is often present when this association occurs on serpentine soils.

Mixed serpentine chaparral occupies an estimated 3,712 acres (0.8%) of the study area (**Table 3-7** and **Figure 3-10**). Mixed serpentine chaparral is found east of U.S. 101 in the small canyons along Coyote Ridge and in small patches at higher elevations mostly in Henry W. Coe State Park. Small patches are also found on either side of Highway 152 near Pacheco Peak, in the upper Llagas Creek watershed, and in the vicinity of Anderson Reservoir and Dam. Mixed serpentine chaparral is most abundant (although never common) in the Santa Cruz Mountains south of Calero Reservoir and west of Morgan Hill.

Covered plants that may be found on this land cover type include, coyote ceanothus, Loma Prieta hoita, and most beautiful jewel-flower (**Table 3-6**). Several covered wildlife species may be found in this land cover type as well. Given the presence of adjacent aquatic habitat, California tiger salamander, California red-legged frog and western pond turtle may use mixed serpentine

chaparral as movement, aestivation, or foraging habitat. Bay checkerspot butterfly uses mixed serpentine chaparral as movement habitat (**Table 3-5**).

### **Northern Coastal Scrub/Diablan Coastal Scrub**

*Northern coastal scrub/Diablan coastal scrub* is composed primarily of evergreen shrubs with an herbaceous understory in openings. This land cover type is usually found at elevations below 300 feet (California Partners in Flight 2004).

On aerial photographs, Northern Coastal Scrub appeared a distinctive shade of pale turquoise-green in summer images and pale tan in fall and winter images; this land cover type typically occurs on south facing slopes, often in relatively small stands interspersed with annual grassland and oak woodland.

Northern coastal scrub/Diablan coastal scrub communities are dominated by California sagebrush and black sage, with associated species including coyote brush, California buckwheat (*Eriogonum fasciculatum*), poison-oak, and bush monkey flower (Holland 1986). Northern coastal scrub/Diablan coastal scrub occurs on both serpentine and non-serpentine substrate; however Northern coastal scrub that occurred on mapped serpentine soils was mapped as serpentine chaparral. The dominant woody plants in this land cover type are nearly the same among different soil types. Northern coastal scrub/Diablan coastal scrub in the study area includes the following vegetation associations based on quantitative vegetation sampling conducted on Coyote Ridge (Evens and San 2004).

- **California sagebrush-coyote ceanothus shrubland.** This association is found on serpentine and on the edges of serpentine on non-marine sedimentary substrate. California sagebrush and coyote ceanothus dominate the sparse shrub layer. Foothill pine is found in the sparse conifer tree layer. Toyon is also common. California yerba santa, Torrey's melic grass, bigberry manzanita, slender wild oats, coyote brush, small-flowered needlegrass, Napa star thistle, common yarrow, woolly-fruited lomatium, hoary coffeeberry, California bee-plant, blue elderberry, and lichen may be present in low amounts. Coyote ceanothus has a strong affinity for serpentine substrates.
- **California sagebrush/California poppy-grass shrubland.** This association is found on serpentine and on the edges of serpentine (on non-marine sedimentary substrate). California sage is the dominant shrub in a relatively open shrub layer (5–45% cover on Coyote Ridge). Slender wild oat, foxtail brome, California poppy, soft brome, and purple needlegrass are common associates. Common yarrow, Santa Clara Valley dudleya, nude buckwheat, Torrey's melic grass, Italian ryegrass, woolly-fruited lomatium, small-flowered needlegrass, Napa star thistle, and blue dicks may also be present.
- **California sagebrush-black sage shrubland.** This association, characterized by California sagebrush and black sage, is also found on serpentine and diabase. The shrub layer is relatively open (30–40% cover on Coyote Ridge) and the herbaceous layer is a minor component. Species

present include bigberry manzanita, coyote brush, toyon, foxtail brome, chaparral mallow, bush monkey flower, and coast live oak.

- **Black sage (pure) shrubland association.** This association occurs on serpentine on northwest- and southwest-facing slopes. Black sage forms a sparse to relatively dense cover of shrubs (average 54% cover on Coyote Ridge). California sage may be present at very low cover. The herbaceous layer is almost non-existent. Other species occasionally encountered are coast live oak, chamise, bigberry manzanita, blue elderberry, poison-oak, Napa star thistle, and scarlet pimpernel.

Northern coastal scrub/Diablan coastal scrub occupies an estimated 10,306 acres (2.2%) of the study area scattered throughout the Santa Cruz Mountains and Diablo Range (**Table 3-7** and **Figure 3-10**).

Covered plants that may be found on this land cover type fragrant fritillary, and most beautiful jewel-flower (**Table 3-6**). Several wildlife species may be found in this land cover type as well. Given the presence of adjacent aquatic habitat, California tiger salamander, California red-legged frog and western pond turtle may use northern coastal scrub/diablan coastal scrub as movement, upland, or foraging habitat (**Table 3-5**).

### **Coyote Brush Scrub**

*Coyote brush scrub* is a type of northern coastal scrub dominated by coyote brush. Common associated shrub species in Santa Clara County include California sagebrush, California lilac (*Ceanothus* spp.), lupine species, bush monkey flower, hoary coffeeberry, and poison-oak. This land cover type is generally found on windy, exposed sites with shallow, rocky soils (Holland 1986); it also occurs on river terraces. Typically it represents the first stage (and least mature in terms of composition development) of scrub occupation of former grassland sites in the succession stage described above (Ford and Hayes 2007). Coyote brush scrub occupies an estimated 180 acres (0.04%) of the study area (**Table 3-7** and **Figure 3-10**). In the study area, it is found adjacent to a few riparian areas and on mid-slopes in the northeastern portion of the study area.

Several wildlife species may be found in this land cover type. Given the presence of adjacent aquatic habitat, California tiger salamander, California red-legged frog and western pond turtle may use northern mixed chaparral/chamise chaparral as movement, upland, or foraging habitat. Bay checkerspot butterfly uses this land cover as movement habitat (**Table 3-5**).

## **Ecosystem Functions**

### **Function and Integrity**

Northern coastal scrub/Diablan sage scrub and coyote brush scrub intermingle with California annual grassland, northern mixed chaparral/chamise chaparral, coastal prairie (grassland), and mixed evergreen forest (Ford and Hayes 2007) and serve as an important corridor for wildlife. In addition, small mammals tend to forage on grassland species that are close to shrub canopies because they

afford greater protection (Keeley 2000). Because sage scrub species are less woody than chaparral species and tend to direct their energy to leaf growth, the structure of coastal scrub communities tends to be open with an herbaceous ground layer (California Partners in Flight 2004). This open structure is important to the white-crowned sparrow (*Zonotrichia leucophrys nuttalli* and *Z. l. pugetensis*) and the sage sparrow (*Amphispiza belli*). The Allen's hummingbird (*Selasphorus sasin*) and the orange-crowned warbler (*Vermivora celata lutescens*) are also associated with this land cover type. The leaves of sage scrub contain important nutrients for herbivorous insects, more so than northern mixed chaparral/chamise chaparral. Peak leaf nutrient levels in scrub appear to coincide with the height of bird breeding season and may be an important food source (California Partners in Flight 2004). California sage and black sage, members of both northern coastal scrub/Diablan sage scrub and northern mixed chaparral/chamise chaparral communities, are important food resources for small mammals, reptiles, and bird species. In addition, both communities have a relatively low proportion of nonnative species due to dense shrub canopies, soil types, and dry conditions, and thus are important resources to wildlife.

The fire-following forbs associated with northern mixed chaparral/chamise chaparral are abundant for one or more years after a fire and provide high-quality habitats for a diversity of insects and other wildlife. The unique flora of post-fire chaparral contributes to its trait of supporting the highest concentration of special-status plants of any community in California (California Native Plant Society 2001). Many species that inhabit chaparral also inhabit adjacent grassland and oak woodlands; however, some birds and mammals are found largely in the dense cover and shade of mature chaparral stands.

### Natural Disturbance

Many of the plants in the chaparral and northern coastal scrub communities have evolved to be dependent on periodic fire for regeneration (Holland 1986; Hanes 1988; Schoenherr 1992). In fact, communities dominated entirely by chamise cannot sustain themselves in the absence of fire (U.S. Fish and Wildlife Service 2002). Some species of chaparral have peeling bark or volatile oils that promote fire (Schoenherr 1992). Many of the dominant shrubs, such as manzanita and ceanothus, have adapted to fire by resprouting from basal burls or woody root crowns following a fire event. Other species have seeds that require fire to initiate growth (U.S. Fish and Wildlife Service 2002; Rundel and Gustavson 2005). Regrowth is triggered by removal of the overstory, typically by fire. Chemicals in smoke and charred wood also stimulate germination in a wide variety of native forbs that lie dormant as seeds in the soil for decades before a fire. Fire occurrence that is too frequent, however, can lead to the elimination of these communities altogether and promote annual grassland succession.

Ford and Hayes (2007) described the dynamic successional relationship between California grasslands and northern coastal scrub. Frequent fire, rodent herbivory, livestock grazing and trampling, and drought tend to maintain grassland and limit succession from grassland to northern coastal scrub as well as the succession from scrub to mixed oak woodland. The succession from grassland to scrub can be as rapid as >5% per year after suppression of fires and livestock grazing, and the succession from scrub to woodland can occur within 50 years after that.

Returning such sites to grassland would typically require management that included manual clearing and herbicides or repeated burning at times of maximum herbaceous understory and dry weather, followed by at least moderate intensity summer seasonal or year-long livestock grazing.

### Threats

Threats to chaparral and northern coastal scrub include habitat fragmentation and loss due to urbanization, fire suppression, competition, and/or hybridization with nonnative plants, trampling, and natural events (U.S. Fish and Wildlife Service 2002).

Fire-suppression policies and growth of human habitation in chaparral and shrub communities pose a great threat to these communities. With buildup of fuel over many years, the risk of catastrophic fire is greatly increased (U.S. Fish and Wildlife Service 2002). Such a fire can kill threatened and endangered wildlife, which might otherwise be able to escape. Severe topsoil erosion is also a problem after these intense fires (Schoenherr 1992). Native serpentine chaparral is threatened by air pollution and resultant nitrogen deposition. Nitrogen enrichment fosters the invasion of nonnative species that replace native ones (Weiss 1999).

## Oak Woodland

The most common land cover types in the study area are dominated by upland hardwood trees, usually various species of oaks (*Quercus* sp.). These land cover types were defined as part of the *oak woodland* natural community, an upland tree-dominated community with at least 10% cover of hardwood tree species. The oak-dominated land cover types that occur in the study area are listed below.

- Valley oak woodland.
- Mixed oak woodland and forest.
- Coast live oak woodland and forest.
- Blue oak woodland.
- Foothill pine-oak woodland.
- Mixed evergreen forest.

CDFG considers valley oak woodland and blue oak woodland sensitive biotic communities (California Department of Fish and Game 2007).

### Historical Extent and Composition

Oak woodland land cover types were historically more extensive and less fragmented relative to current conditions. The deep alluvial soils found throughout the lowland areas of the Santa Clara Valley formerly supported a wide range of oak forests and woodlands. Historical photos, maps, and

observational accounts indicate that large areas of the Santa Clara Valley within the Coyote Watershed were dominated by Valley oak woodland, all of which has been converted to urban development and agricultural uses (Grossinger et al. 2006).

Native Americans and European settlers manipulated local oak woodlands, through burning, grazing, and planting, to serve their needs. Large shifts in the composition and function of oak woodland communities began with the gold rush and increased in the latter part of the 20<sup>th</sup> century when previously grazed oak woodlands were converted to rural residential parcels leading to a decline in abundance and distribution of these oak communities (Pavlik et al. 1991). Recent studies show that the median parcel size in parts of California once dominated by oaks has decreased exponentially, from 550 acres in 1957 to just nine acres in 2001. As a result, the urban interface with oak woodlands is much more pervasive than at any other time in history (Giusti et al. 2004).

## Common Wildlife Associations

Oak woodlands provide food and cover for many species of wildlife (County of Santa Clara 2005). Mature oak trees bear natural cavities, which are important resources for cavity-nesting birds and small mammals. Also, mature oak forests typically contain snags (standing dead trees), which are valuable resources for woodpeckers because they prefer dead trees and limbs for excavation of roost and nest sites (Thomas 1961). Snags receive high levels of use by secondary cavity-nesting birds (e.g., chickadees and wrens) and mammals. Snags also support wood-boring insects that provide food for bark-gleaning insectivorous birds. Oak forests also provide acorns, which as a seasonal food are important for the survival of many species of wildlife in fall and winter. Birds that are dependent on acorns as a seasonal food include acorn woodpeckers, scrub-jays, band-tailed pigeons, and California quail.

Characteristic wildlife species that can be found in these land cover types include amphibian species such as California red-legged frog and California tiger salamander that use these habitat types for summer aestivation and movement when aquatic habitats are present; reptile species such as gopher snake and western fence lizard; bird species such as red-tailed hawk, American kestrel, barn owl (*Tyto alba*), great horned owl (*Bubo virginianus*), acorn woodpecker (*Melanerpes formicivorus*), Nuttall's woodpecker (*Picoides nuttallii*), northern flicker (*Colaptes auratus*), white-breasted nuthatch (*Sitta carolinensis*), California quail, spotted towhee (*Pipilo maculatus*), Bewick's wren, and bushtit (*Psaltiriparus minimus*); and mammal species such as deer mouse (*Peromyscus maniculatus*), western gray squirrel (*Sciurus griseus*), mule deer, and coyote (County of Santa Clara 2005).

Oak woodland-associated wildlife species covered by the Plan include Bay checkerspot butterfly, California tiger salamander, California red-legged frog, western pond turtle, tricolored blackbird, and San Joaquin kit fox (**Table 3-5**).

California tiger salamanders use the grassy understory of open woodlands for terrestrial aestivation or refuge and aquatic sites for breeding. The California red-legged frog uses this habitat type for breeding, foraging, and refugia. The western pond turtle utilizes aquatic habitat often found in oak woodlands. The turtle is known to overwinter in leaf litter or soil at upland sites. San Joaquin kit foxes may use this community for movement through the study area. The western burrowing owl uses open woodlands, with low-stature vegetation for foraging and burrowing. Bay checkerspot butterfly may use this community for movement between habitat patches.

## Oak Woodland Land Cover Types

The six different oak woodland land cover types mapped showed quite different signatures on aerial photographs, in terms of color and texture, and each typically occupied different landscape positions.

### Valley Oak Woodland

Valley oak woodland was distinguished by a combination of crown size and spacing and landscape position. In the Plan study area, valley oak tree crowns are typically larger than any other oak species except some blue oaks, and are typically well-spaced; valley oak woodland is almost always adjacent to annual grassland and either mixed oak or blue oak woodland types.

Although valley oak is typically found in alluvial soils in California, it also occurs in nonalluvial sites on broad ridgetops and mid-slope benches. *Valley oak woodland* is characterized by a fairly open canopy of mature valley oaks with a grassy understory, generally on valley bottoms and north-facing slopes (Griffin 1971; Holland 1986; Sawyer and Keeler-Wolf 1995). Valley oak woodlands often form a mosaic with annual grasslands, and are also found adjacent to other land cover types, including mixed oak woodland, blue oak woodland, and riparian woodland types. Valley oak woodland is generally denser on valley bottoms where the tree roots can penetrate to the groundwater, and less dense on ridges where trees need wider spacing to develop larger root systems (Griffin 1973).

Trees in the valley oak community are typically mature and well spaced. They are usually the only trees present in this open-canopy woodland, have no shrub layer, and the understory is dominated by nonnative annual grasses. As with most oak communities, regeneration typically is episodic, occurring periodically in “mast years” when acorn production is high and some acorns germinate by avoiding acorn predators such as acorn woodpeckers and California ground squirrels. Creeping wild rye, poison-oak, mugwort (*Artemisia douglasiana*), and California rose (*Rosa californica*) are common native species in riparian portions of valley oak woodland.

Covered plants that may be found within the valley oak woodland include Santa Clara Valley dudleya, fragrant fritillary, and Loma Prieta hoita (**Table 3-6**). These species are restricted to specific habitat elements and micro-site characteristics within this land cover. Valley oak woodland occupies

approximately 12,895 acres (2.8%) of the study area (**Table 3-7** and **Figure 3-10**). This land cover type is most common on the valley floors of the southeast corner of the study area, but it also occurs on ridgetops in the central eastern portion of the study area.

### **Mixed Oak Woodland and Forest**

The *mixed oak woodland and forest* land cover type is a significant land cover type in the study area. It contains oak woodland habitats where no species is clearly dominant, or where different types of oak woodlands are present in a small-scale mosaic and each type occurs in patches too small to map. It includes a mixture of live and deciduous oaks; foothill pine may be present as scattered individuals.

Mixed oak woodland and forest in the Plan study area is generally a closed-canopy woodland, with the signature on aerial photographs showing a variety of colors and textures of the different oak species; winter images clearly show that deciduous and evergreen oaks are mixed. This land cover type occurred on a variety of aspects and slope positions, and was typically adjacent to other oak woodland types.

Covered plants that may be found within mixed oak woodland and forest include Santa Clara Valley dudleya, fragrant fritillary, and Loma Prieta hoita (**Table 3-6**). These species are restricted to specific habitat elements and micro-site characteristics within this land cover. Mixed oak woodland and forest occupies approximately 84,488 acres, (18.4%) of the study area (**Table 3-7** and **Figure 3-10**). It is found predominantly at middle elevations in the foothills of the Diablo and Santa Cruz Mountains on either side of Santa Clara Valley. It is, taxonomically, the broadest and most geographically widespread of the oak woodland land cover types in the study area. It was mapped in most areas within the study area where oaks are found, with the exception of an eastern portion of the study area where foothill pine-oak woodland is dominant.

### **Coast Live Oak Woodland and Forest**

The *coast live oak woodland and forest* land cover type mostly includes stands of coast live oak, although California bay is often a major component, and other live oaks and scattered deciduous trees are often present.

Coast live oak woodland and forest was identified by its closed canopy and even dark green color that was the same in all seasons, and by its landscape position, occurring generally on north-facing valley slopes and valley bottoms. There was often an abrupt transition between annual grassland and coast live oak woodland, with coast live oak woodland occupying valley slopes and annual grassland occurring on the surrounding ridges. Coast live oak woodland also occurred adjacent to other oak woodland types.

Grasses and herbs are common in this land cover type. Other species found in this cover type include coffeeberry, bush monkey flower, redberry buckthorn, and California sagebrush (Allen-Diaz et al. 1999). In addition, California blackberry (*Rubus ursinus*), bugle hedge nettle (*Stachys ajugoides*), wood fern (*Dryopteris arguta*), and poison-oak are often present.

Across the Central Coast Ranges, stands occur at lower elevations (200–3,250 feet, mean 1,205 feet) on north and northeast aspects. Slopes are generally steep (36% on average), and parent material is primarily sedimentary sandstone and shale, with loam soils (Allen-Diaz et al. 1999).

Covered plants that may be found within coast live oak forest and woodland include Santa Clara Valley dudleya, fragrant fritillary, and Loma Prieta hoita (**Table 3-6**). These species are restricted to specific habitat elements and micro-site characteristics within this land cover.

Coast live oak woodland and forest occupies approximately 31,652 acres of the study area (6.9%) of the study area (**Table 3-7** and **Figure 3-10**).

### **Blue Oak Woodland**

*Blue oak woodland* is highly variable in the study area, occurring as single-species canopy stands with virtually no shrub layer understory or with a shrub layer of California sage, as open-canopy stands of widely spaced, mature trees on broad ridges, and as more mixed overstory stands with a dense and diverse shrub understory.

Blue oak woodland was identified by the color of the canopy: pale to mid green in summer imagery in contrast to coast live oak, and leafless in winter imagery. The canopy of blue oak woodland could be closed or relatively open. Aspect was important in distinguishing blue oaks from other deciduous oak species: blue oak woodland in the study area typically occurred on south-facing aspects; however, ridge-top stands of large, well-spaced blue oaks also occurred, and could be difficult to distinguish from valley oaks.

Blue oak woodland is dominated by blue oak (*Quercus douglasii*), a highly drought-tolerant species adapted to growth on thin soils in the dry foothills. Blue oaks grow slowly in these soils and may take decades to reach maturity. They generally occur on sites that are drier and have lower levels of nitrogen, phosphorus, and organic matter than those where valley oak or coast live oak are found (Griffin 1973; Baker et al. 1981). Although blue oaks can become established on south-facing slopes during wetter years or where mesic conditions are present, they are generally found on north-facing slopes (Griffin 1971). However, in the Central California Coast Ranges, blue oak woodland is more common on south-facing slopes (Miles and Goudey 1997). California buckeye and foothill pine are associate tree species in this community.

The understory varies from shrubby to open, with a composition similar to that of the adjacent nonnative grassland. Understory species include annual grasses, hollyleaf cherry, poison-oak, and coffeeberry. Blue oak woodland is considered a sensitive community by CDFG (California Department of Fish and Game 2007) when the following species are present: blue oak, valley oak, and coast live oak.

Fragrant fritillary is the only covered plant that may be found within blue oak woodlands (**Table 3-6**). This species is restricted to specific habitat elements and micro-site characteristics within this land cover.

Blue oak woodland and forest occupies approximately 11,160 acres (2.4%) of the study area (**Table 3-7** and **Figure 3-10**). It is present in scattered locations mostly in the low to mid-elevation hills of the watershed on dry or well-drained north or northeast facing slopes.

### **Foothill Pine-Oak Woodland**

Foothill pine-oak woodland was identified by the obvious signatures on aerial photographs of well-spaced emergent foothill pine crowns, which appear pale gray-green with clear shadows over the lower canopy of contrasting darker green evergreen oaks. Foothill pine-oak woodland often occurred along valley floors within chaparral communities in the eastern foothills, and also occurred adjacent to other oak land cover types and on serpentine soils.

Found at elevations ranging from 200–2,100 feet, foothill pine integrates with blue oak and mixed oak woodlands at higher elevations, forming the *foothill pine-oak woodland* land cover type. Here, the canopy is dominated by emergent foothill pine with a typically dense understory of scattered shrubs, often those found in adjacent chaparral and scrub communities, and nonnative annual grasses and forbs. Oaks become more prevalent at lower elevations, often forming a closed canopy layer below the emergent pines, and the understory lacks an appreciable shrub layer. In the foothills to the east, associated canopy species include blue oak, interior live oak, coast live oak, and California buckeye (Griffin 1977). Closer to the coast, coast live oak, valley oak, blue oak, and California buckeye are typically found.

Associated shrub species include ceanothus species, bigberry manzanita, California coffeeberry, poison-oak, silver lupine (*Lupinus albifrons*), blue elderberry, California yerba santa, rock gooseberry (*Ribes quercetorum*), and California redbud (*Cercis occidentalis* [*C. orbiculata*]).

Covered plants that may be found within foothill pine-oak woodlands include fragrant fritillary and Loma Prieta hoita (**Table 3-6**). These species are restricted to specific habitat elements and micro-site characteristics within this land cover.

Foothill pine-oak woodland occupies approximately 10,960 acres (2.4%) of the study area (**Table 3-7** and **Figure 3-10**). It is found throughout the hills of the Diablo range in the eastern pocket of the study area, interspersed with stands of blue oak.

### **Mixed Evergreen Forest**

Mixed evergreen forest was identified on aerial photographs primarily by its geographic location and aspect; it occurred on the west side of the valley usually on north-facing slopes. The closed canopy was dark green on imagery from any season, but appeared less even in texture than coast live oak woodland because of the mix of different tree species.

Dominant species in the *mixed evergreen forest* land cover type are evergreen broadleaved trees, such as California bay, madrone, tanoak (*Notholithocarpus* [*Lithocarpus*] *densiflorus*), and all three species of live oak: coast live oak, interior live oak (*Quercus wislizenii*), and canyon live oak (*Quercus chrysolepis*).

Conifers—Douglas fir (*Pseudotsuga menziesii*), Coulter pine (*Pinus coulteri*), and foothill pine—occur occasionally as scattered individuals. Deciduous species such as California buckeye and bigleaf maple (*Acer macrophyllum*) frequently occur in this land cover type. The transition between oak woodland and mixed evergreen forest land cover types in the study area is gradual and is characterized by a decrease in cover of live oaks and an increase in California bay, madrone, and tanoak.

Similar to the understory of oak woodlands, the understory of mixed evergreen forest varies from dense shrub thickets to areas dominated by sparse grass and forb cover. Water and light availability appear to be the controlling factors in determining the density of understory vegetation. Mixed evergreen forests lack drought adaptations and generally grow in more mesic habitats (Griffin 1971, 1973). North-facing slopes with well-drained, coarse soils provide ideal substrate conditions. The understory vegetation of mixed evergreen forests consists primarily of shade-tolerant species, such as toyon, poison-oak, and various species of ferns, due to low light levels underneath the canopy (Parker and Muller 1982; Marañón and Bartolome 1994).

Covered plants that may be found within mixed evergreen forest include Santa Clara Valley dudleya, fragrant fritillary, and Loma Prieta hoita (**Table 3-6**). These species are restricted to specific habitat elements and micro-site characteristics within this land cover.

Mixed evergreen forest occupies approximately 5,775 acres (1.3%) of the study area (**Table 3-7** and **Figure 3-10**). In the study area, it occurs on slopes with north and northeast aspects, almost exclusively at the western boundary of the study area, along high-elevation ridges in the Santa Cruz mountains.

## Ecosystem Functions

### Function and Integrity

Oak woodlands perform a variety of ecological functions, including nutrient cycling, water storage and transport, and wildlife habitat (Giusti et al. 2004). Oak woodlands share many of the same functions as the adjacent grassland and chaparral communities. However, the structure and food provided by the dominance of oak trees in this community distinguish it from the other natural community types. Oak woodland is one of the most biologically diverse communities in California, providing essential habitat for approximately 2,000 plant, 5,000 insect, 80 amphibian and reptile, 160 bird, and 80 mammal species (Merelender and Crawford 1998). Large acorn crops and a diverse insect fauna provide high-quality food for a wide variety of amphibians, reptiles, birds, and mammals.

Dense oak woodlands provide cool, shady refugia for wildlife during the hot, dry summer, and more sparse oak woodlands offer raptors ideal hunting perches. Open-canopy oak woodlands provide critical upland habitat for California tiger salamander, which aestivates in burrows in the grassland understory or beneath isolated oaks. These oak woodlands also provide nesting and foraging habitat for

a variety of bird species. The grassland understory provides habitat for fossorial rodents such as ground squirrels and gophers, which are prey for red-tailed hawks, coyotes, and great horned owls. Rodent burrows, in turn, provide habitat for a variety of other species, including burrowing owls.

### **Natural Disturbance**

Oak woodland is a fire-adapted ecosystem, and fire has likely played a large role in maintaining this community type in the study area. Fire creates the vegetation structure and composition typical of oak woodlands, and this natural community has experienced frequent, low-severity fires that maintain woodland or savannah conditions. In the absence of fire, the low or open understory that characterizes the land cover type is lost. Ultimately, closed-canopy oak forests are replaced by shade-tolerant species because oaks cannot regenerate and compete in a shaded understory. Soil drought may also play a role in maintaining open-tree canopy in dry woodland habitat.

Grazing, including precolonial grazing by deer and elk, may also have helped to maintain a more open understory that favors oaks and grasses.

### **Threats**

The two main processes influencing the prevalence of oak woodlands in California are land conversion (for development and intensive agriculture) and the parcelization of large blocks of contiguous habitat for urban development (Giusti et al. 2004).

A lack of oak regeneration, which may be related to development pressures, is also a serious threat for some species. Shortages of apparent regeneration are reported for stands of valley oak, blue oak, and coast live oak. Where regeneration is a problem, mature trees and seedlings are usually adequately abundant, but intermediate-sized trees and saplings are rare or uncommon, suggesting the mature trees will not be replaced (McCreary 2009). Research on the causes of this decline has yet to identify a single causal mechanism. However, potential interacting mechanisms include livestock herbivory and trampling, fire suppression, noxious weed invasion, herbivory by small mammals, and the dominance of annual grasses (over native perennial grasses) that compete with the oak seedlings for soil moisture during the critical early spring period. McCreary (2009) provides a decision-key for determining whether a stand of oaks has a regeneration problem.

Recent research on the effects of wild pigs in California showed that they can disturb up to 35–65% of the ground annually where they occur in high densities, and that they significantly reduce acorn survival (Sweitzer and Van Vuren 2002). In addition to feral pigs, a high density of invasive weeds and nonnative plants in the understory affect oak regeneration. Some studies have found browsing by deer livestock, or other large mammals to be an important factor negatively impacting recruitment (Borchert et al. 1989; Bartolome et al. 2002). Another study found that herbivory by small mammals (Tyler et al. 2002) is very detrimental to oak recruitment. Recruitment in many tree species, particularly oaks, can be highly cyclical and dependent on long-term rainfall patterns.

A more recent influence on oak woodlands is sudden oak death. The disease, first identified in 1995, has since spread to 12 counties and killed tens of thousands of oaks. Research indicates that coast live oaks and black oaks appear to be the most susceptible to this disease (Rizzo et al. 2003). Sudden oak death, caused by the pathogen *Phytophthora ramorum*, is a serious threat to oak woodlands and mixed evergreen forests in northern California. The pathogen can kill adult oaks and madrone; California bay, buckeye, and maple host the pathogen without being killed by it. Blue oak and valley oak have not shown symptoms of the pathogen. Sudden oak death has been confirmed in San Mateo, Santa Cruz, Alameda, Contra Costa, and Santa Clara Counties. It is unknown whether climatic or other factors will limit the spread of sudden oak death into the study area.

Due to the rarity and slow regeneration of some species of oak, several oak-dominated land cover types are considered sensitive communities by CDFG (Table 3-1).

Additionally, when urban land is in close proximity to these land cover types, there is a considerable reduction in habitat value. Noise, light, irrigation, and frequent disking for fire protection can substantially degrade habitat conditions. Habitat is also threatened by invasion of exotic plant species in the understory.

## Riparian Forest and Scrub

Riparian vegetation in the study area was classified into three land cover types.

- Willow riparian forests, woodlands, and scrub.
- Central California sycamore alluvial woodland.
- Mixed riparian woodland and forest.

CDFG considers central California sycamore alluvial woodland a sensitive biotic community (California Department of Fish and Game 2007).

Because stream systems are so closely tied to riparian forest and scrub land cover, the *riverine* land cover type is also discussed in this section.

## Historical Extent and Composition

From the foothills to the valley floor, riparian forest, woodland, and scrub communities surround riverine watercourses, thriving along stream banks and floodplains. While the largest and most diverse riparian forests occurred on mainstem rivers with natural levees, well-developed riparian forest and scrub was found along virtually all watercourses in central California (Katibah 1984). Historically, riparian vegetation was shaped by its proximity to streams and was maintained by seasonal flooding in the winter and spring and by summer drought. Riparian forests developed on the natural levees of river-deposited silt, lining many of the study area's drainages. Virtually all streams supported dense

vegetation from the water's edge to the outer moist-soil zone, whether or not natural levees were present. Precolonial riparian vegetation was characterized by corridors of dense, broadleaf vegetation of varying widths bounding the stream channel with widths determined by local geologic and hydrologic conditions (Katibah 1984).

With the gold rush in 1849, rapid development of some portions of California began. Riparian vegetation removal was one of the first significant losses in the natural environment. Although they are more fragmented today, these land cover types still support many plant species and a diverse collection of birds, amphibians, and mammals. Significant impacts have also resulted from the expansion of agriculture and livestock grazing, along with water diversion and flood control projects (Katibah 1984).

Historically, most of Coyote Creek along the valley floor may have been intermittent (often with isolated persistent pools) or dry during dry years and droughts while in wet years much of the stream may have been perennial. Streams draining the Diablo Range traveled overland, down the mountain slopes until reaching the valley floor where water spread out over the loose alluvial soils, percolating into the groundwater basin (Grossinger et al. 2006). Water traveled underground until reaching the main stem of Coyote Creek, where it surfaced and continued to drain through the salt marshes and into the San Francisco Bay. As land was claimed for agriculture, streams leading from the mountains were channelized into ditches to be used for drinking water and irrigation. The modern-day network of constructed drainage ditches and channels took place largely prior to 1900. Today nearly 50% of the valley floor watercourses draining into Coyote Creek are constructed channels (Grossinger et al. 2006).

The two main tributaries to the Guadalupe River, Guadalupe Creek and Los Gatos Creek, were historically connected to the Guadalupe River much as they are today. Much like the small tributaries of Coyote Creek, smaller tributaries of the Guadalupe River, such as Ross Creek, historically percolated into the valley floor but were not connected via surface flow to the Guadalupe River. Today, many of these small tributaries are now connected to the Guadalupe River via man-made channels (Oakland Museum of California n.d.). The Guadalupe River historically flowed into Guadalupe Slough but has since been redirected to Alviso Slough for navigation purposes.

As discussed above, the existing stream network was largely developed through human intervention and has been manipulated by the introduction of canals and ditches to provide additional flexibility in water supply, to increase the amount of developable land around streams, and to reduce flooding in the valley. As such, channels and ditches now cross between previously disparate riverine systems. One example of this is the Coyote-Alamitos Canal that was built to carry water from the Coyote Canal along Coyote Creek to Alamitos Creek and the Guadalupe percolation basin in the Almaden Valley (Horii 2004).

Historically, the defining feature of the Pajaro River watershed was a broad lowland basin that straddled the south Santa Clara County/north San Benito

County border. Covering 14 miles between Gilroy and Hollister, the remnants of this natural basin are now referred to as the Soap Lake floodplain. This historical basin was fed by the converging alluvial fans of Llagas Creek, Uvas/Carnadero Creek, and Pacheco Creek. As the streams left their steeper alluvial fans and converged into the basin, they tended to have less well defined channels than at present. Streamflow spread into an array of wet meadows, freshwater marshes and ponds, and willow swamps, and eventually coalesced again into a well-defined channel—the origin of the Pajaro River (San Francisco Estuary Institute 2007).

The head of the Pajaro River was originally wetlands associated with San Felipe Lake, a sag pond within the greater Soap Lake floodplain, located near Highway 152 east of Gilroy. When the Soap Lake floodplain was inundated, the lake and wetlands drained into the river. To facilitate agricultural development in the late 19<sup>th</sup> century, Miller Canal was constructed from San Felipe Lake directly to a downstream portion of the Pajaro River near its confluence with Llagas Creek, bypassing the flat, meandering wetland channel (San Francisco Estuary Institute 2007). The canal allowed for quicker spilling of the lake at a lower elevation, allowing farming around the lake. The original upper Pajaro River channel is now a shallow, seasonal ditch. Additional channelization of both Lower Llagas Creek and Cardanero (Uvas) Creek in the late 1800's eliminated much of the historic seasonal flows received by the Soap Lake Basin.

## Common Wildlife Associations

Riparian habitats provide food, water, migration and dispersal corridors, and nesting and cover habitat for numerous wildlife species (Grenfell 1988). These habitats have high value due to their limited extent and widespread use by an abundant and diverse assemblage of wildlife species.

Wildlife species that are often associated with this land cover type include amphibians such as Pacific tree frogs (*Pseudacris regilla*), California newts (*Taricha torosa*), and California slender salamander (*Batrachoseps attenuatus*); reptiles such as western aquatic garter snake (*Thamnophis couchii*) and San Francisco garter snake (*Thamnophis sirtalis tetrataenia*); birds such as Wilson's warbler (*Wilsonia pusilla*), Swainson's thrush (*Catharus ustulatus*), California yellow warbler (*Dendroica petechia brewsteri*), green heron (*Butorides striatus*), wood duck (*Aix sponsa*), spotted towhee, and red-shouldered hawk (*Buteo lineatus*); and mammals such as long-tailed weasel (*Mustela frenata*), San Francisco dusky-footed woodrat (*Neotoma fuscipes annectens*), gray fox (*Urocyon cinereoargenteus*), mountain lion (*Puma concolor*), and California myotis (*Myotis californicus*).

Riverine systems, particularly healthy riverine systems, provide habitat for aquatic macroinvertebrates, which are an important food source for local and downstream populations of birds and other animals.

Bay checkerspot butterfly and California tiger salamander use riparian forest and scrub land cover as movement habitat. California red-legged frog uses riparian

habitat type for breeding, foraging, and refugia. Foothill yellow-legged frog (*Rana boylei*) and western pond turtle utilize aquatic habitat for thermoregulation, foraging, and avoidance of predators. The turtle is also known to overwinter in leaf litter or soil at upland sites and uses sparsely-vegetated upland sites for nesting. Least Bell's vireo has been found foraging in riparian areas in the southern portion of the county and may be nesting, especially when a dense shrub layer exists, although no confirmed nests have been found. Tricolored blackbird uses this land cover type as breeding and year-round habitat. San Joaquin kit fox has been known to use this land cover as movement habitat.

Loma Prieta hoita is the only covered plant associated with riparian forest and scrub land cover types (**Table 3-6**).

Riverine associated wildlife species covered under this Plan that are known to occur in the study area include Bay checkerspot butterfly (for movement), California red-legged frog, foothill yellow-legged frog, western pond turtle, least Bell's vireo (*Vireo bellii pusillus*), tricolored blackbird, and San Joaquin kit fox (**Table 3-5**).

## Riparian Forest and Scrub Land Cover Types

Within the Plan study area, riparian forest and scrub land cover types were identified primarily by their landscape position along creeks and around open water bodies. Several common riparian trees species—willows, cottonwood, and sycamore—appeared to hold their leaves after they turn color in fall, and early winter imagery clearly showed these distinctive yellow crowns, either in pure stands or mixed with the dark green canopies of coast live oak and bay in more mixed riparian woodland. The plant assemblage and width of riparian corridors found along the banks and floodplains of rivers and streams, vary. Dominant influencing factors include the steepness of the channel, the frequency of disturbance, and the hydrologic regime present.

The *riparian forest and scrub* land cover type is dominated by woody vegetation associated with permanent water sources. Riparian woodland is dominated by trees and contains an understory of shrubs and forbs. Riparian scrub is dominated by young willow trees and shrubs, typically representing an early successional stage of riparian woodland.

At the state level, riparian plant communities are considered sensitive because of habitat loss and their value to a diverse community of plant and wildlife species. Additionally, CDFG has identified them as a sensitive natural community (California Department of Fish and Game 2007).

### Willow Riparian Forests, Woodlands, and Scrub

*Willow riparian forests, woodlands, and scrub* land cover types occur in and along the margins of active channels on intermittent and perennial streams. Yellow willow (*Salix lasiandra*), red willow (*Salix laevigata*), arroyo willow (*Salix lasiolepis*), and narrowleaf willow (*Salix exigua*) are the dominant canopy species in this habitat. In addition, Fremont cottonwood, white alder (*Alnus*

*rhombifolia*), bigleaf maple, California sycamore (*Platanus racemosa*), and coast live oak are often found in these communities.

A range of conditions exists among the willow riparian forest, woodland, and scrub communities. Forests are typically composed of dense, mature willows integrating with central coast live oak riparian forest and white alder riparian forest on well-established stream terraces, often with scattered California sycamore trees. Woodland communities contain dense willow riparian scrub, dominated by young trees and shrubs, on young and dynamic alluvial deposits. Scrub communities typically consist of scattered willows and mulefat (*Baccharis salicifolia*) occurring in and along the margins of open sandy washes. Understory development in willow forest or scrub land cover types is controlled by canopy density.

Willow riparian forests, woodlands, and scrub occupy approximately 2,544 acres (0.6%) of the study area (**Table 3-7** and **Figure 3-10**). This land cover type is associated with streams throughout the study area. Particularly large stands of this land cover types are found along the major creek and streams including Guadalupe River, Coyote Creek, Uvas Creek, Llagas Creek, Pacheco Creek, and the Pajaro River along the county line.

Willow riparian forests, woodland, and scrub provide important habitat for many covered wildlife species (**Table 3-5**). For example, this land cover type provides the primary habitat for least Bell's vireo in the study area. California red-legged frog and western pond turtle will also utilize this land cover type within the aquatic systems. The California tiger salamander moves through or forages in this land cover type.

### **Central California Sycamore Alluvial Woodland**

Central California sycamore alluvial woodland was readily identified by the large well-spaced sycamore crowns. In early winter aerial imagery the large pale branches and halo of fallen golden-yellow leaves were visible. The landscape position, on broad alluvial valley floors, was also indicative of this land cover type.

The *central California sycamore alluvial woodland* land cover type is generally present on broad floodplains and terraces along low gradient streams with deep alluvium. Areas mapped as sycamore alluvial woodland are generally open canopy woodlands dominated by California sycamore, often with white alder and willows (*Salix* spp.). Other associated species include bigleaf maple, valley oak, coast live oak, and California bay.

The understory is disturbed by winter flows, and herbaceous vegetation is typically sparse or patchy. Typically, plants such as willows, coyote brush, mulefat, California buckeye, blackberry, Italian thistle (*Carduus pycnocephalus*), poison-oak, common chickweed (*Stellaria media*) and bedstraw (*Galium aparine*) populate the stream banks.

Central California sycamore alluvial woodland occupies 367 acres (0.1%) of the study area (**Table 3-7** and **Figure 3-10**). All stands of this land cover type are

found along Coyote Creek and Pacheco Creek. Air photos and field mapping conducted by CDFG of this land cover type in 1992 identified only 17 major stands statewide occurring on 2,032 acres (Keeler-Wolf et al. 1997). Among the stands mapped by this project were three sites in the study area on Coyote Creek (40.1 acres between Ogier Ponds and Anderson Dam), Upper Coyote Creek (49.2 acres above Coyote Reservoir), and on Pacheco Creek along Highway 152 (135.4 acres). At that time, the study area supported 11% of this land cover type in the state. All stands were also quantitatively sampled by CDFG, providing a basis for a detailed description of this land cover type in California. Results from the CDFG study differ from the mapping conducted for the HCP/NCCP (225 acres vs. 374 acres<sup>16</sup>). Sycamore woodland is also found along lower Cedar Creek (a tributary to Pacheco Creek) and the North Fork of Pacheco Creek upstream of Pacheco Reservoir.

California red-legged frog and western pond turtle may be found in this land cover type year-round, while California tiger salamander and foothill yellow-legged frog may move through this land cover type (**Table 3-5**). Least Bell's vireo may forage in this land cover type.

### **Mixed Riparian Woodland and Forest**

*Mixed riparian woodland and forest* land cover types are similar to willow riparian forests and woodlands in species occurrences. They are found in and along the margins of the active channel on intermittent and perennial streams. Generally, no single species dominates the canopy, and composition varies with elevation, aspect, hydrology, and channel type. This land cover type captures much of the riparian woodland and forest in the study area and includes several associations that could not be distinguished on the aerial photographs. The major canopy species throughout the study area are California sycamore, valley oak, coast live oak, red willow, and California bay. Associated trees and shrubs include California black walnut, other species of willow, California buckeye, Fremont cottonwood, and bigleaf maple. Nonnative invasive species that may be present include giant reed (*Arundo donax*) and Himalayan blackberry (*Rubus armeniacus* [*R. discolor*]).

Covered plants that may be found within mixed riparian forest and woodlands are limited to Loma Prieta hoita (**Table 3-6**). This species is restricted to specific habitat elements and micro-site characteristics within this land cover.

Mixed riparian woodland and forest occupies approximately 3,717 acres (0.7%) of the study area (**Tables 3-7** and **Figure 3-10**). Mixed riparian is found in association with streams throughout the study area.

Covered species associated with this land cover type are the same as willow riparian forests, woodlands, and scrub (**Table 3-5**).

<sup>16</sup> Differences in results are likely due to differences in mapping techniques, differences in air photos used, and changes in environmental conditions over the 13 years between the studies.

### Riverine (Streams)

The *riverine* land cover type includes perennial, intermittent, and ephemeral watercourses characterized by a defined bed and bank. *Perennial streams* support flowing water year-round in normal rainfall years. These streams are often marked on USGS quadrangle maps with a blue line, known as *blue-line* streams. In the semi-arid Mediterranean climate of the study area with its wet and dry seasons, perennial stream flows are enhanced in the dry season through groundwater aquifer contributions, flows from shallower springs/seeps, and reservoir releases. *Intermittent (seasonal) streams* carry water through most of the wet season (November–April) and are dry through most or all of the dry season (May–October) in a normal rainfall year. More specifically, in the wet season, intermittent streamflow occurs when the water table is raised, or rejuvenated, following early season rains that fill shallow subsurface aquifers. Intermittent flows can also be considered as the ‘baseflows’ between storm events that continue on through much of the winter season. *Ephemeral streams* carry water only during or immediately following a rainfall event. The principal named waterways in the northern half of the study area (the Santa Clara Basin) are perennial due to urban runoff, reservoir releases, and/or high groundwater (Santa Clara Basin Watershed Management Initiative 2003). The principal waterways in the Pajaro River Basin have some perennial reaches due to a combination of high groundwater levels (primarily in headwater reaches of tributaries and in the Pajaro River), agricultural runoff, and releases from dams in the valley floor reaches.

The riverine land cover type is most closely associated with riparian plants (see the *Riparian Forest and Scrub* section above for discussion of riparian land cover types). The riparian plant composition and width of the riparian corridor vary depending on channel slope, magnitude and frequency of channel and overbank flows, and the frequency/duration of flooding flows that inundate the broader floodplain. Some of the riverine areas in the study area, particularly on the valley floor streams include braided stream forms with multiple channel threads and swales, intermediary channel bars, raised side channel benches (that are still actively flooded), and higher terrace sequences that may no longer be actively flooded. In such systems where there is frequent flooding, gravel bars with mulefat scrub occur as an early seral community (Santa Clara Basin Watershed Management Initiative 2003). Willows may become established in-channel in areas of sediment deposition, unless suppressed by intensive browsing by wildlife or livestock, lack of water, or high flows. Woody debris, such as fallen trees that are submerged in streams, provides good habitat and shelter for aquatic invertebrates.

Several invasive, nonnative plant species are found in riverine land covers within the study area. One of the most prevalent is giant reed, which is often found in large pure stands. Other invasive, nonnative plants potentially found in the study area include blue gum eucalyptus, acacia, fennel (*Foeniculum vulgare*), periwinkle, English ivy, French broom, black locust, Algerian ivy (*Hedera canariensis*), Cape ivy, Himalayan blackberry, weeds, curly dock (*Rumex crispus*), thistle, blackwood acacia (*Acacia melanoxylon*), tree-of-heaven (*Ailanthus altissima*), glossy privet (*Ligustrum lucidum*), fig, poison hemlock,

black mustard, black walnut, and almond (Santa Clara Basin Watershed Management Initiative 2003).

Major streams in the study area include Coyote Creek, Guadalupe River, Uvas Creek, Llagas Creek, Pajaro River, Pacheco Creek, and their various tributaries (**Figure 3-6**). Riverine habitats were not mapped as polygons but are derived from USGS and SCVWD stream data. Based on this information there are an estimated 3,032.2 miles of riverine habitat in the study area.

Wildlife species covered by this Plan that may be found living in or nearby the riverine land cover type include California tiger salamander, California red-legged frog, foothill yellow-legged frog, and western pond turtle (**Table 3-5**).

Common fish species found in the watersheds draining towards San Francisco Bay (Guadalupe River and Coyote Creek) include native species such as California roach (*Lavinia symmetricus*), hitch (*L. exilicauda*), Sacramento sucker (*Catostomus occidentalis*), threespine stickleback (*Gasterosteus aculeatus*), resident rainbow trout and anadromous steelhead (*Oncorhynchus mykiss*), prickly sculpin (*Cottus asper*), and riffle sculpin (*Cottus gulosus*), and introduced fishes such as green sunfish (*Lepomis cyanellus*), largemouth bass (*Micropterus salmoides*), and mosquitofish (*Gambusia affinis*). Common native fish species found in the Pajaro River Watershed including Uvas, Llagas, and Pacheco Creek, include resident rainbow trout and anadromous steelhead, hitch (*Lavinia exilicauda*), California roach (*Lavinia symmetricus*), Sacramento blackfish (*Orthodon microlepidotus*), Sacramento sucker, threespine stickleback, Sacramento pikeminnow (*Ptychocheilus grandis*), riffle sculpin and prickly sculpin (J. Smith pers. comm. 2007).

Native and nonnative fish assemblages and in-stream aquatic habitat types throughout the major stream systems in the study area are shown in **Figure 3-12** and described in detail in **Appendix L**. The figure illustrates the distribution of the native fish assemblages and riverine habitat types developed for the Science Advisors report (Spencer et al. 2006) and updated by SCVWD fisheries biologist Jae Abel for the GIS layer. **Table 3-8** documents the relationship of the native fish communities to native fish.

Canals and ditches were included in the riverine land cover type due to their similar function to degraded streams and their very low acreage in the study area. Due to the nature of these man-made structures, canals and ditches are often managed for minimal vegetation to enhance the flow of water through the channels. Vegetated canals and ditches that cross serpentine areas (e.g., Coyote Ridge, Santa Teresa Hills) often support several covered species including Santa Clara Valley dudleya, most beautiful jewelflower, smooth lessingia, Mt. Hamilton thistle, and California red-legged frog. Garter snakes and some ducks use canals and ditches throughout the study area.

## Ecosystem Functions

### Function and Integrity

While riparian land cover types occupy a very small percentage of the total land cover in the study area, they are particularly important because they are among the most structurally complex and richly diverse habitat types in terms of plant and animal associations.

Riparian communities support both terrestrial and aquatic species by providing movement corridors across the landscape and both nesting and foraging habitat. They can also support high levels of invertebrate production; provide moist, cool refugia during the hot, dry summer; have moderate stream temperatures; help armor stream banks; and support the aquatic food chain by means of input of vegetative and other detritus.

Riparian areas are integrated into the working rangelands of the study area. They are typically managed in conjunction with adjacent grasslands, shrublands, and oak woodlands. They are often used by livestock for forage, shade and drinking water.

Denser canopies reduce direct solar radiation to streams and creeks, thereby lowering water temperatures and may increase habitat value for aquatic wildlife. However, algal growth, which increases aquatic insects, requires a partially open canopy for light. Differences in vegetative structure between riparian communities lead to varying effectiveness in providing these ecosystem functions. For example, riparian scrub, with its lower vegetation structure, is often less effective in reducing stream temperatures than riparian woodland. On the other hand, riparian scrub may provide better nesting and foraging habitat for migratory passerine birds that prefer the dense thicket habitat provided by scrub. Living and dead woody debris that enter the stream channel from the riparian forest provides valuable habitat benefits for native fish.

Physically, riverine systems, most notably natural streams, provide the essential conduits to convey flows, sediments, and nutrients across the watershed. Streams transport weathered minerals and eroded sediments from upper watershed source areas through intermediate watershed positions ultimately to lower watershed depositional areas or discharges beyond the watershed. While the general, and classical, characterization of watersheds into 'upper erosional', 'middle transitional', and 'lower depositional' areas may often hold true; in greater detail, all areas of the watershed can witness erosion, transport, or storage functions. Nutrients from exposed soil and decomposed organic matter are also carried downstream with the sediment, across the valley floor and finally into the estuary. Alluvial soils, high in organic content and nutrients, are excellent for agriculture. Sediment influx to estuaries helps maintain a marshland buffer along the shoreline that supports a myriad of wildlife.

Streams provide ecosystem functions and values much greater than the proportion of the landscape they occupy. Streams provide habitat for a wide array of aquatic insects that, in turn, function as food for amphibians, birds, and other insectivorous species. Perennial streams function as permanent water

sources in an otherwise dry landscape. Streams also provide movement corridors between different terrestrial communities. In this way, networks of ephemeral, seasonal, and perennial streams link chaparral/scrub, oak woodland, oak savanna, riparian woodland, and grassland habitats. These links are not only important for the movement of wildlife, but also represent the fastest means of transporting energy and nutrients through a watershed. Thus, it is through stream networks that organic matter and minerals are transported from the highlands and deposited in the lowlands.

Stream channels are modified for a variety of purposes. In the study area, stream channels are modified primarily for flood conveyance, ground water percolation, and agricultural and drinking water distribution. Canals and ditches are usually hardened structures for the transport of water for agricultural irrigation and urban and suburban uses. Earthen levees or channel walls are a common, engineered stream channel modification to protect property adjacent to streams from flooding. Most stream channel alterations, whether hardened structures like canals, or earthen structures such as some ditches and levees, are designed to convey water quickly, to either reduce evapotranspiration (water lost to the atmosphere) during transport, costs associated with water delivery, or to increase the flow, and thus the volume of runoff, that can be moved out of areas prone to flooding. Regardless of the type of modification, the result is often the same—a more linear alignment that does not allow a channel to meander as it would in its natural state. This results in higher flows and potential scour of the stream channel, in hardened structures such as canals, this scour typically occurs upstream and/or downstream of the solid infrastructure. Channel modifications and/or solid infrastructure such as canals also disconnect the stream from the floodplain, resulting in the loss of nutrient delivery upstream and increased sediment deposition downstream.

Agricultural ditches often play a key role in providing connectivity between larger open space areas, especially in urbanizing areas such as the Santa Clara Valley. Maintaining connectivity between open space patches that provide habitat supports a diversified genetic pool due to the ability of populations to disperse and co-mingle. Agriculture also often is associated with streams, canals, and ditches used for irrigation that may support riparian vegetation, trees (planted as windbreaks), and shrubs. These areas may provide habitat to songbirds, raptors, amphibians and reptiles, as well as provide a movement corridor for other species.

### **Natural Disturbance**

Riparian communities are shaped by their proximity to water and by periodic flooding that maintains the structure and composition of this land cover type. Wet-season flooding replenishes alluvial soils that are deficient in minerals and organic matter. Flooding also subjects riparian forest to frequent disturbance that benefits regeneration of certain species, including California sycamore, white alder, and black willow. Regeneration from seed appears to occur in pulses correlated with large flood events (Shanfield 1984). Additionally, trees that are damaged by flooding can resprout from the roots and trunk (Shanfield 1984).

The flowing nature of streams encourages regular mixing as water flows over rocks, tree stumps, and changes gradient. Depending on other environmental influences including temperature and dissolved oxygen levels, mixing may also trigger the hatching of larvae that will become food for fish, birds, and bats. Erosion and sedimentation processes are forms of natural and artificial disturbance in the area. Flood and drought cycles of natural streams tend to result in a mosaic of structure and composition in riparian plant communities (this mosaic may be lost in altered flow regimes downstream of reservoirs). Flooding is also a key disturbance process that has largely been eliminated from portions of the study area. For example, large flood-control projects on the Guadalupe River and Coyote Creeks have greatly reduced flooding frequency and intensity. Similarly, channelization of Llagas Creek and portions of Uvas Creek has reduced (but not eliminated) flooding in Morgan Hill and Gilroy, respectively. Flooding still occurs regularly in the Soap Lake area (lower Llagas Creek, lower Pacheco Creek, and upper Pajaro River).

### Threats

In the greater Bay Area, flood control activities, cultivated agriculture, aggregate mining, and urban development have significantly reduced the distribution of this land cover type. Riparian forest can also be severely impacted by improper grazing management. Therefore it is possible that this cover type was much more abundant prior to the onset of intensive livestock grazing. Finally, seedling establishment and growth is heavily dependent on access to surface water or shallow groundwater during the majority of the year (Sacchi and Price 1992). As such, water operations and land alterations that result in reduced stream baseflows and/or increased depth to the water table will have a significant negative effect on this land cover type. Sycamores in the study area, including those that dominate Sycamore alluvial woodland, are frequently infected by Sycamore anthracnose (*Apiognomonina veneta*), a fungal disease that affects trees throughout the state (Keeler-Wolf et al. 1997).

Livestock grazing can substantially degrade riparian woodland and scrub communities when cattle and other livestock have uncontrolled access to streams. However, modifying traditional grazing practices can protect riparian areas. Using shortened grazing periods during times of increased vulnerability (late summer and fall) can reduce damage to the vegetation, eliminate or reduce impacts to soils, and buffer the overland transport of sediments and nutrients from grazed lands into the surface water.

All riverine systems within the study area have been altered significantly by human impacts including impoundments, creation of permanent or temporary barriers to movement, water diversions, channelization, flood control projects, loss of riparian vegetation, and increased rates of sedimentation. These impacts reduce habitat complexity and habitat quality, affecting such things as pool/riffle relationships, level of dissolved oxygen, and substrate composition. Loss of riparian vegetation results in decreased shading, increased water temperatures, reduced cover, and decreased input of nutrients (Santa Clara Basin Watershed Management Initiative 2003). Trash and other pollutants that are washed into streams may degrade water quality to the point the aquatic life cannot persist.

Aquatic invertebrates, often sensitive to water quality, may die off, thus disrupting the food chain.

## Conifer Woodland

In addition to hardwood-dominated upland land cover types, conifer dominated land cover types also occur in the study area. The three conifer-dominated communities listed below occur in the study area.

- Redwood forest.
- Ponderosa pine woodland.
- Knobcone pine woodland.

## Historical Extent and Composition

Prior to European settlement, the Santa Clara Valley supported a mosaic of plant and wildlife communities. Upland regions were heavily forested with redwoods that flanked creeks and rivers as they traversed the landscape to lower elevations. Under mesic habitat conditions, pine and oak forests dotted the land (Bolton 1927, 1930). The foothill forests and woodlands were heavily thinned in the mid- to late-1800s to house and support the growing population in the region. With habitat alterations came the replacement of native plant communities with nonnative, invasive species. These new communities contain lower quality habitat for native wildlife species.

## Common Wildlife Associations

Wildlife species often found in conifer dominated upland land cover types include: birds such as acorn woodpecker, scrub-jay (*Aphelocoma californica*), California quail, golden eagle, Cooper's hawk (*Accipiter cooperii*), olive-sided flycatcher (*Contopus cooperi*), and sharp-shinned hawk (*Accipiter striatus*); amphibians such as arboreal salamanders (*Aneides* spp.), California slender salamander, and California newt; reptiles such as common king snake (*Lampropeltis getula*), garter snake (*Thamnophis* spp.), and ringneck snake (*Diadophis* spp.); and mammals such as broad-footed mole (*Scapanus latimanus*), deer mouse, western gray squirrel, gray fox, and striped skunk (*Mephitis mephitis*).

Associated wildlife species covered under this Plan that are known to occur in the study area include California tiger salamander, foothill yellow-legged frog and western pond turtle (**Table 3-5**).

California tiger salamanders use the grassy understory of open woodlands for terrestrial aestivation or refuge and aquatic sites for breeding. Foothill yellow-legged frogs and western pond turtles utilize aquatic habitat often found in

redwood forest and oak woodlands. The turtle is also known to overwinter in leaf litter or soil at upland sites.

## Conifer Woodland Land Cover Types

Coast redwood (*Sequoia sempervirens*) forests are primarily distributed in the Santa Cruz Mountains. They occur in ravines, along streamsides, and in areas that are moistened by coastal fog (Thomas 1961). At higher elevations of the Diablo Range, stands of ponderosa pine (*Pinus ponderosa*) are found. Stands of knobcone pine (*Pinus attenuata*) occur on ridgetops of the Santa Cruz Mountains at the western edge of the study area.

### Redwood Forest

Redwood forest was identified on aerial imagery by the large, irregular crown outlines formed by the whorled branches, and by the landscape position along creeks and valleys and on lower north- and east-facing slopes in the foothills on the western side of the valley. The irregular crown signatures on aerial photographs contrasted with the adjacent land cover types, usually mixed oak woodland or mixed evergreen woodland.

The *redwood forest* land cover type is dominated by an overstory of redwood with a variety of associated tree, shrub, and forb species in the understory. This land cover type is uncommon in the study area, only occurring in the Santa Cruz Mountains in the west portion of the study area along creeks and valleys, generally on north-facing slopes. Stands of redwoods are found along Uvas (Uvas Canyon County Park), Llagas, and Arthur Creeks. Most redwood forests have been logged since the second half of the nineteenth century, and most of the existing trees are stump sprouts. However, in many areas, particularly along creeks, dense cover of redwood trees has been maintained. Areas that were burnt following logging now support chaparral or oak-dominated communities. Redwood forests occur in areas that receive substantial rainfall, generally more than 35 inches per year. Common plants associated with these forests include trees such as tanoak, madrone, and California bay; the shrub layer include species such as hazelnut (*Corylus cornuta* var. *californica*), thimbleberry (*Rubus parviflorus*), and black huckleberry (*Vaccinium ovatum*). In riparian areas, California bay and bigleaf maple are common, California nutmeg (*Torreya californica*) may occur, and ferns such as sword fern (*Polystichum munitum*) often form a dense layer.

Redwood forest occupies approximately 9,628 acres (1.9%) of the study area (**Table 3-7** and **Figure 3-10**). This land cover type is found in the study area exclusively in the Santa Cruz Mountains, mostly along drainages and near ridgelines.

Covered wildlife species that may be found in this land cover type California red-legged frog, foothill yellow-legged frog, and western pond turtle (**Table 3-5**).

Fragrant fritillary and Loma Prieta hoita may occur within redwood forest landcover, however, data is insufficient for the study area (**Table 3-6**). These

species would be restricted to specific habitat elements and micro-site characteristics within this land cover.

### **Ponderosa Pine Woodland**

Ponderosa pine woodland has a very restricted distribution within the Plan study area and was identified by the widely-scattered dark green crowns of individual Ponderosa pine trees, which cast long oblong shadows across the adjacent grassland.

The *Ponderosa pine woodland* type is dominated by an overstory of ponderosa pine, with oaks and oak woodland understory species as associates. This land cover type is uncommon in the study area, only occurring on three high elevation ridges in Henry W. Coe State Park—Pine Ridge, Middle Ridge, and Blue Ridge—and extending downslope into north-facing canyons and valleys. On the ridges, Ponderosa pine trees are often large and well spaced, forming very open stands over annual grassland. Regeneration is often common and many age classes are present. Associated tree species include black oak (*Quercus kelloggii*), coast live oak, and Pacific madrone. Few shrubs are present, although bigberry manzanita is common in some areas. Ponderosa pine is uncommon in the Coast Ranges; these stands are likely relicts of a wider distribution in the past when the climate was cooler.

Ponderosa pine woodland occupies approximately 419 acres (0.1%) of the study area (**Table 3-7** and **Figure 3-10**).

California tiger salamander, California red-legged frog and western pond turtle may move through this land cover type during dispersal events (**Table 3-5**).

Loma Prieta hoita may occur within ponderosa pine woodlands, however, data is insufficient for the study area (**Table 3-6**). This species would be restricted to specific habitat elements and micro-site characteristics within this land cover.

### **Knobcone Pine Woodland**

Knobcone pine woodland was identified by its geographical location on ridges in the western portion of the Plan study area and the mid-green, relatively even signature on aerial photographs contrasting with adjacent signatures of redwood forest, northern mixed chaparral, and mixed evergreen forest.

*Knobcone pine woodland* land cover types consist of dense stands of knobcone pines that regenerate following fire. This land cover type is uncommon in the study area, occurring only in the Santa Cruz Mountains on ridgetop sites, often on serpentine-derived soils. It is thought that the water-retaining properties of serpentinite, combined with the pine's ability to intercept marine fog, allow knobcone pine to persist in these locations (Vogl 1973). Knobcone pine is an obligate fire-climax species—fire is required to melt the resin that seals the cones, releasing the seed, and fire also creates the bare mineral soil required for the seeds to germinate. Stands of knobcone pine are therefore even-aged, dating back to the last stand-replacing fire. Knobcone pine is fast growing, with a relatively short lifespan of 75 to 100 years, although approximately half the trees may die by 60 years of age (Vogl 1973). Knobcone pine woodland is replaced

by chaparral at lower elevations and by conifers (redwood or Douglas fir) at higher elevations, and it may occur as a mosaic with chaparral, conifer- and oak-dominated woodlands. Although knobcone pine usually occurs as dense, monodominant stands, it can also be associated with chaparral species such as manzanitas, bush poppy (*Dendromecon rigida*), and bush chinquapin (*Chrysolepis chrysophylla* var. *minor*) that form a sparse to dense understory layer.

Knobcone pine woodland occupies an estimated 711 acres (0.1%) of the study area (**Table 3-7** and **Figure 3-10**). This land cover type is found along the summit of the Santa Cruz mountains at the western edge of the study area.

Covered species do not forage and breed in this land cover type. Species that may move through this land cover type include California red-legged frog and western pond turtle (**Table 3-5**).

Fragrant fritillary and Loma Prieta hoita may occur within land cover type; however, data is insufficient for the study area (**Table 3-6**). These species would be restricted to specific habitat elements and micro-site characteristics within this land cover.

## Ecosystem Functions

### Function and Integrity

Similar to oak woodland, these forests and woodlands provide food, nesting, and cover to a variety of wildlife. However, the structure and food resources that conifer-dominated forests provide make them a valuable resource. Evergreen oaks such as coast live oak, as well as California bay, madrone, and foothill pine, provide year round shelter unlike the largely deciduous vegetation of riparian forest and scrub. A largely continuous, dense leaf canopy and abundant tree cavities act to shade wildlife, provide habitat for nesting, and offer protection from predators. In addition, thick layers of leaf litter, ephemeral ponds, and wetlands can provide secondary habitat for soil invertebrates and amphibians by offering protection from desiccation and foraging habitat.

### Natural Disturbance

A major factor influencing the distribution of conifer-dominated land cover types is fire intensity and frequency. The combination of logging and burning at the end of the nineteenth century resulted in the conversion of conifer-dominated forests (redwood and Douglas fir) in the Santa Cruz Mountains to chaparral and oak-dominated woodlands. Periodic stand-replacing fire is required for the regeneration of knobcone pine woodland.

### Threats

Conifer-dominated land cover types have been heavily affected by timber harvesting, urban development, and agricultural conversion. When urban land is adjacent to or surrounds these natural communities, there is a significant reduction in habitat value. Noise, light, irrigation, and frequent disking for fire protection can substantially degrade habitat conditions and the chance of fire

increases. Habitat is also threatened by invasion of exotic plant species in the understory.

## Wetlands

Wetland habitat includes areas subject to seasonal or perennial flooding or ponding, or that possess saturated soil conditions and that support predominantly hydrophytic or “water-loving” herbaceous plant species. Because wetlands are periodically waterlogged, the plants growing in them must be able to tolerate low levels of soil oxygen associated with waterlogged or hydric soils. The presence of flood-tolerant species is often a good indication that a site is a wetland even if the ground appears to be dry for most of the year (Barbour et al. 1993; Santa Clara Valley Water District 2002a), or if hydrologic influences are less obvious.

Wetland habitat in the study area was classified into two land cover types.

- Coastal and valley freshwater marsh.
- Seasonal wetland.

In general, wetlands represent a sensitive biotic community due to their limited distribution and importance to special-status plant and wildlife species.

## Historical Extent and Composition

Wetland habitats, in particular seasonal wetlands, were almost certainly more abundant in the study area than they are today. Historically, vernal pools and other seasonal wetlands and ponds were likely scattered throughout the lowland portions of the study area and streams flowed unimpeded by the channels, water diversions, and barriers that are present today. At the time of the Portola expedition in 1769, large marshes, especially near the lower portions of Coyote Creek and the Guadalupe River, reportedly made overland travel by foot very difficult (Santa Clara Basin Watershed Management Initiative 2003).

Two large freshwater wetland areas, Laguna Socayre and Laguna Seca, were located within the Coyote Watershed prior to reclamation activities. These lagunas were a type of perennial emergent freshwater wetland that has groundwater at or near the surface through most, if not all of the year. Laguna Socayre, located east of downtown San José, above and below Capitol Expressway between Story and Tully Road, was a series of historic freshwater wetlands, which included a large freshwater marsh which partly overlaps with modern-day Lake Cunningham (Grossinger et al. 2006). It was created by an old levee of Coyote Creek and intercepted flood flows from the surrounding tributary creeks and may have received emergent groundwater as well. Laguna Seca in Coyote Valley, was an approximately 1,000-acre spring-fed perennial wetland complex formed as the Santa Teresa Hills forced groundwater to the surface. Drainage was blocked by the bedrock of the Santa Teresa Hills and the natural levees of Coyote Creek (Grossinger et al. 2006). In certain years

during the dry season, Laguna Seca would dry up completely. It was reclaimed from 1916–1917.

In the low-lying bottomlands, poorly drained basin areas between alluvial fans, flooded wet meadows or marshes sometimes were formed around smaller perennial freshwater marshes and lagunas. In addition, the heavy organic clay soils characteristic of the bottomland areas, often referred to as “black adobe” soils resulted in surface expression of groundwater in seasonally flooded wet meadows and perennial wetland complexes (Grossinger et al. 2006). In addition, bedrock hills prevented drainage of the lower Coyote Valley, which created vast wet meadows with perennial marshes and ponds. The natural levees of Coyote Creek and flat topography also prevented surface runoff and helped created these wet meadows. The dominant plant species in wet meadows or marshes were probably rhizomatous ryegrasses (*Elymus* spp.) (Grossinger et al. 2006). Large stands of saltgrass and alkali meadow were also extensive in the Coyote Watershed, particularly in the lowlands near lower Penitencia Creek and downgradient from Laguna Socayre (Grossinger et al. 2006). Remnant stands of alkali meadows are still present around the fringes of Lake Cunningham in San José. Historic patterns of wetlands in the Guadalupe Watershed are likely to be similar to those in the Coyote Creek Watershed. In the Uvas/Llagas/Pacheco/Pajaro watersheds seasonal or perennial wetlands were present near the mouths of Uvas and Llagas creeks, and the Soap Lake wetland complex of wetlands, vernal pools and alkali meadows was much more extensive than at present in the upper Pajaro River/lower Pacheco Creek area (San Francisco Estuary Institute 2008).

In a statewide study of vernal pools, CDFG identified large portions of Santa Clara County as potentially supporting vernal pools based on the presence of vernal pool species<sup>17</sup> (California Department of Fish and Game 1998). Vernal pools recognized in Santa Clara County are fault-zone sag-pond pools and serpentine vernal pools (California Department of Fish and Game 1998; Santa Clara Basin Watershed Management Initiative 2003). A vernal pool just north of the study area in southern Alviso is known to have existed prior to urban development in the area (Sally Casey pers. comm. 1998 in Santa Clara Basin Watershed Management Initiative 2003). Detailed investigations of historic records of wetlands and other land cover types in the Coyote Creek Watershed revealed no evidence of historic vernal pools (R. Grossinger pers. comm.). Vernal pools may have always been rare in the study area.

European settlement saw the introduction of nonnative aquatic species such as the bullfrog, into wetland habitats. Those areas whose hydrology has been altered by damming (e.g., stock ponds) or channelization have been particularly impacted.

<sup>17</sup> Vernal pools in most other regions were identified based on the unique signature on air photos of vernal pool landscapes and wetland complexes.

## Common Wildlife Associations

Wetland land cover types provide drinking water, as well as foraging, breeding, and resting habitat for many forms of fish and wildlife, including birds, amphibians, reptiles and mammals. Wetlands provide stopovers for many species of waterfowl and songbirds. Many wildlife species, particularly invertebrates, spend their entire lives in wetlands.

Perennial wetlands are important habitat for a wide variety of wildlife species. Representative waterbirds that forage and rest in permanent wetlands and associated open-water areas include great blue heron (*Ardea herodias*) and great egret (*Ardea alba*); as well as various ducks, including wood duck, green-winged teal (*Anas crecca*), mallard (*Anas platyrhynchos*) and American coot (*Fulica americana*); killdeer (*Charadrius vociferus*); and greater yellowlegs (*Tringa melanoleuca*). Typical amphibians and reptiles in this cover type include red-legged frog, western pond turtle, and garter snakes. Many of the larger mammals, such as mule deer, may frequent permanent wetlands and use them as a source of drinking water.

Seasonal wetlands (i.e., wet meadows, seeps) are commonly used by a variety of wildlife during the wet season, including various amphibians such as Pacific chorus frog (*Pseudacris regilla*), western toad (*Bufo boreas*), and California tiger salamander; shorebirds such as killdeer, black-necked stilt (*Himantopus mexicanus*), and American avocet (*Recurvirostra americana*); and passerines such as Brewer's blackbird (*Euphagus cyanocephalus*), red-winged blackbird (*Agelaius phoeniceus*), brown-headed cowbird (*Molothrus ater*), and American pipit (*Anthus rubescens*). During the dry season, a variety of small mammals may use seasonal wetland areas as forage source, including deer mouse, California vole, and long-tailed weasel; however, wet meadows and seeps are generally too wet to provide suitable habitat for small mammals. Raptors such as white-tailed kites, northern harrier, and red-tailed hawk may forage in this land cover type.

Wetland-associated wildlife species covered under this Plan include bay checkerspot butterfly, California tiger salamander, California red-legged frog, western pond turtle, western burrowing owl, tricolored blackbird (*Agelaius tricolor*), and San Joaquin kit fox (**Table 3-5**).

## Wetland Land Cover Types

Within the study area, wetlands were identified and mapped on the basis of their aerial photograph signatures and landscape positions that would support wetland hydrology. In late season imagery, wetlands appear greener than surrounding annual grassland. The minimum mapping unit for all wetland land cover types was 0.25 acre, with the exception of serpentine seeps (see *Grasslands*), which had no minimum mapping unit. Wetland subtypes were distinguished based on the color and texture of the signature on air photos.

On early spring imagery, coastal and valley freshwater marsh appeared pale brown and rough in texture because the emergent plants (cattails and bulrushes) have died back and have not yet started to grow. In contrast, at this time of year, seasonal wetlands appeared dark green, but are difficult to distinguish from the surrounding annual grassland, which also appears dark green at this time of year. In early winter imagery, both types of wetlands appear dark green, the color of the seasonal wetlands contrasting with the adjacent annual grasslands, which at that time of year appeared brown.

The USFWS's National Wetlands Inventory (NWI) data layer was examined and compared with the aerial photographs to assist in the recognition of additional wetland areas, particularly seasonal wetlands with ambiguous signatures.

### **Coastal and Valley Freshwater Marsh**

*Coastal and valley freshwater marsh* is dominated by emergent herbaceous plants (reeds, sedges, grasses) with either intermittent flooded or perennially saturated soils. Freshwater marshes are found throughout the coastal drainages of California wherever water slows down and accumulates, even on a temporary or seasonal basis. A freshwater marsh usually features shallow water that is often clogged with dense masses of vegetation, resulting in deep peaty soils. Plant species common to coastal and valley freshwater marsh predominantly consist of cattails (*Typha* spp.), bulrushes (*Schoenoplectus* and *Bolboschoenus* spp.), sedges (*Carex* spp.), and rushes (*Juncus* spp.). Dominant species in perennial freshwater wetland in the study area include rabbitsfoot grass (*Polypogon* sp.), nutsedge (*Cyperus eragrostis*), willow weed (*Persicaria lapathifolia* [*Polygonum lapathifolium*]), and water cress (*Rorippa* spp.). Broadleaf cattail (*Typha latifolia*) and water-primrose (*Ludwigia* spp.) are common associates (Jones & Stokes 2000). Dominant species in nontidal freshwater marsh are narrow-leaved cattail (*Typha angustifolia*), rice cutgrass (*Leersia oryzoides*), bur-reed (*Sparganium eurycarpum*), alkali bulrush (*Bolboschoenus* [*Scirpus*] *robustus*), and perennial peppergrass (*Lepidium latifolium*) (Jones & Stokes 2002).

Coastal and valley freshwater marsh occupy an estimated 381 acres (0.1%) of the study area (**Table 3-7** and **Figure 3-10**). This land cover type is generally found in lowland areas adjacent to diked tidal wetlands, along the margins of lakes and reservoirs, and along the lower reaches of the Guadalupe River and Coyote Creek, upstream of tidal influence (Santa Clara Basin Watershed Management Initiative 2003). Wetlands in the study area range in size from less than an acre to up to 42 acres. The largest wetland can be found along Coyote Creek north of Morgan Hill and just west of U.S. 101. Along the lower reaches of the Guadalupe River and Coyote Creek, freshwater wetlands transition downstream into wetlands influenced by brackish water with less cattail and other freshwater-adapted species to more salt-tolerant species such as California bulrush.

One of the largest freshwater wetlands in southern Santa Clara County is San Felipe Lake, immediately adjacent to the study area in San Benito County and adjacent to Highway 152. San Felipe Lake, sometimes referred to as Soap Lake, is a natural, seasonal lake, fed by Ortega Creek, Pacheco Creek, and Tequisquita Slough. The lake drains through Millers Canal in San Benito County, which in

turn feeds the Pajaro River. The lake is part of a large floodplain called Bolsa de San Felipe (RMC 2005).

Covered species that may be found breeding in the coastal and valley freshwater marsh land cover type (**Table 3-5**) include tricolored blackbird, California red-legged frog, California tiger salamander, and western pond turtle. In addition, Bay checkerspot butterfly may move through this land cover type.

### Seasonal Wetlands

*Seasonal wetlands* are freshwater wetlands that support ponded or saturated soil conditions during winter and spring and are dry through the summer and fall until the first substantial rainfall. The vegetation is composed of wetland generalists, such as hyssop loosestrife, cocklebur (*Xanthium* spp.), and Italian ryegrass that typically occur in frequently disturbed sites, such as along streams. Common species in seasonal wetlands within the study area include water cress, water speedwell (*Veronica anagallis-aquatica*), and smartweeds (*Persicaria* [*Polygonum*] spp.) (Jones & Stokes 2000). Other dominant species are California aster (*Symphyotrichum chilense* [*Aster chilensis*]), white sweet clover (*Melilotus albus*), and narrow-leaved cattail (Santa Clara Valley Water District 2002a).

Seasonal alkali wetlands historically occurred in two locations in the study area, around what is now Lake Cunningham in San José (San Francisco Estuary Institute 2006) and in the Soap Lake area near the Pajaro River (San Francisco Estuary Institute 2008). Small remnant stands of seasonal alkali wetlands may still persist in these areas but they were too small to be mapped in our regional mapping effort.

Vernal pools are seasonal wetlands that pond water on the surface for extended durations during winter and spring and dry completely during late spring and summer. They support a typical flora largely composed of native wetland plant species. Vernal pools in eastern Alameda and Contra Costa Counties occur in distinctive topography with low depressions mixed with hummocks or mounds.

Vernal swales and pools have been documented from one location in the study area, on private ranches north of Gilroy (WRA Environmental Consultants 2008). These swales and pools are dominated by meadowfoam (*Limnanthes* spp.), button celery (*Eryngium aristulatum* var. *hooveri*), and calicoflower (*Downingia* spp.).

“Vernal basins,” which are seasonal wetland habitats found in grassland swales, have been documented in Coyote Lake-Harvey Bear Ranch (Rana Creek Habitat Restoration 2004)<sup>18</sup>. These basins host a limited flora that includes species such as coyote thistle (*Eryngium vaseyi*), African pricklegass (*Crypsis vaginiflora*), and flowering quillwort (*Triglochin* [*Lilaea*] *scilloides*). Historically, there may have been more vernal pools and vernal basins in the study area.

<sup>18</sup> Features such as these vernal basins or swales may have been the source of the vernal pool records in California Department of Fish and Game (1998).

Seasonal wetlands were first mapped using only air photo interpretation. When only 25 acres were mapped using this method, we supplemented this approach with additional data (NWI data and large project mapping). As a result, 201 acres, (0.04%) of the study area, of seasonal wetlands were mapped in the study area **Table 3-7** and **Figure 3-10**. Seasonal wetlands are likely still underrepresented in the land cover map because of their typically small size, isolated locations, and difficulty in interpreting the photographic signature of individual features. Because the land cover mapping was conducted primarily using aerial photos taken in December (2003 and 2005), some seasonal wetlands may have been mapped as coastal and valley freshwater marsh.

Western burrowing owl, San Joaquin kit fox, and Bay checkerspot butterfly may use seasonal wetlands as movement habitat. Both California tiger salamander and California red-legged frog use this land cover type for breeding and foraging (**Table 3-5**). Western pond turtle uses this land cover type for foraging. Tricolored blackbirds are known to use seasonal wetlands for foraging and breeding habitat.

Fragrant fritillary may occur within seasonal wetland land cover, however, data is insufficient for the study area (**Table 3-6**). This species would be restricted to specific habitat elements and micro-site characteristics within this land cover.

## Ecosystem Functions

### Function and Integrity

Wetland functional values are provided through several physical and biological processes (National Research Council 2001). Perennial and seasonal wetlands function as essential habitat for amphibians that depend on aquatic environments for reproduction and juvenile development. These wetlands also provide high levels of insect production, which in turn creates a major food source for amphibians, birds, and other insectivorous species. The cyclical nature of inundation and drought in seasonal wetlands allows these systems to support a unique suite of highly adapted biota. Perennial wetlands are permanent water sources during the dry season in an otherwise arid landscape and thus function as essential habitat for a wide variety of water-dependant wildlife.

Wetlands also perform important functions with regard to physical processes. For example, wetlands play an important role in regulating biogeochemical cycles such as the nitrogen cycle. Wetlands also mediate flows in local streams and springs by providing temporary surface water storage and gradual recharge to local aquifers. On a small scale, wetlands in the study area also reduce erosion and sedimentation by reducing surface runoff.

Marshes recharge groundwater supplies and moderate streamflow by providing water to streams. This is an especially important function during periods of drought. The presence of marshes in a watershed helps to reduce damage caused by floods by slowing and storing floodwater. As water moves slowly through a marsh, sediment and other pollutants settle down to the bottom of the marsh. Marsh vegetation and microorganisms also use excess nutrients for growth that

can otherwise pollute surface water such as nitrogen and phosphorus from fertilizer.

### **Natural Disturbance**

Seasonal flooding is a key natural disturbance in seasonal wetlands. Marsh and other wetland plant species must tolerate flooding during the growing season and thus be able to tolerate anoxic conditions. Prolonged flooding can kill off wetland plants if the shoots have been destroyed by grazing or fire prior to the flood event (Keddy 2000). Dry periods can function as a disturbance as well. Sediment deposition is a key feature of wetland communities. Seedlings are sensitive to sediment burial, which can prevent or reduce germination (Keddy 2000). As a marsh ages, vegetation accumulates and may fill the pools of open water present which can eventually lead to meadow creation (Faber 1982).

### **Threats**

Threats to wetland land cover types include pollution, grazing, changes in hydrologic regime, conversion to other land uses such as agriculture or urban development, nonnative species invasion, and natural processes such as fire or flood. Fertilizer, pesticides, and untreated sewage contribute to pollution and result in a decrease in oxygen, which can kill vegetation within wetlands. Grazing disturbs the vegetation around marshes and can result in invasion of nonnative plant species into the marsh area (Holland and Keil 1995). The establishment and spread of invasive nonnative species can also result from urban ornamental landscape species (e.g., weeping willow [*Salix babylonica*], red sesbania [*Sesbania punicea*]) that are transported or reseed within drainages and watersheds, ultimately finding their way into downstream wetlands. Hydrologic regime changes can result from the construction of dams and weirs, extraction of groundwater and the creation of artificial drainages. Conversion of land to other uses can lead to the direct loss of wetland habitats as such lands are regraded and/or filled for such uses. In addition, increased stormwater runoff from impermeable surfaces can flow so rapidly into adjacent wetlands that it causes excessive scour and wetland habitat loss. Excessive sediment deposition following fire can virtually fill in wetlands, burying marsh vegetation.

## **Open Water**

*Open water land cover types* consist of open water or aquatic habitats such as lakes, reservoirs, water-treatment ponds, sloughs, and ponds (including percolation and stock ponds) that do not support emergent vegetation. Open water habitat in the study area is classified into two land cover types.

- Pond.
- Reservoir.

Natural lakes were originally included as a separate land cover type. However, no natural lakes were mapped in the study area and therefore are not discussed below.

## Historical Extent and Composition

Open water land cover types were historically less prevalent than they are currently. With only a few exceptions, lakes, reservoirs, and ponds did not exist in the Plan study area until they were built to support livestock and provide a water supply for the population of Santa Clara County.

Very few naturally occurring ponds existed historically in the study area. At least two large perennial freshwater ponds were located along the valley floor in the Coyote Watershed (Grossinger et al. 2006). Beginning in earnest in the mid-1800s with the advent of the gold rush, the population of the Santa Clara Valley grew rapidly. With this growth came ranchers who built hundreds of stock ponds in the study area to water grazing livestock, largely with technical and financial assistance from the U.S. Department of Agriculture (USDA) Soil Conservation Service. Stock ponds continue to dot the study area, including in now-protected open spaces.

Percolation ponds were also built throughout the study area to recharge the groundwater basin during wet and dry seasons. Currently, 71 percolation ponds are managed by SCVWD in the county for this purpose (Santa Clara Valley Water District 2002b). They are actively managed as “industrial water production facilities,” and most are in urbanized areas.

At least one seasonal lake, Laguna Seca, was located at the north end of the area now known as Coyote Valley at the base of the saddle between Tulare Hill and the Santa Theresa Hills (Grossinger et al. 2006). One or two perennial freshwater wetlands, which may have functioned more as a lake than a wetland during the wet season, also existed along the valley floor in the Coyote Creek watershed (Grossinger et al. 2006). These features were drained in 1919 to allow farming in the area.

Most lakes in the study area are man-made reservoirs that were built in the 1930s and 1950s, mostly for water supply purposes. SCVWD owns and operates seven dams and associated reservoirs (Almaden, Anderson, Calero, Coyote, Guadalupe, and Uvas, and Vasona) in the study area for water supply, and one reservoir, Chesbro Reservoir built in 1955, for flood protection and water supply purposes (Santa Clara Valley Water District 2005). Other reservoirs in the study area include the North Fork Pacheco Reservoir (built for agricultural water supply) and several small reservoirs located in unincorporated areas of the County along the western foothills of the Diablo Range.

## Common Wildlife Associations

Open water land cover types provide drinking water, as well as foraging, breeding, and resting habitat for a variety of terrestrial and aquatic wildlife, including birds, amphibians, reptiles, and large mammals. Reptiles such as western pond turtle and garter snakes use available water resources and the

vegetation surrounding open waters as habitat. Mammals use all types of open water resources for drinking and hunting.

All open water land cover types support a variety of ducks including mallard, green-winged teal, cinnamon teal (*Anas cyanoptera*), gadwall (*A. strepera*), American wigeon (*A. americana*), and American coot. Raccoons forage for adult and larval amphibians, fish, and crayfish.

Ponds attract many birds that are normally found in the adjacent grasslands; for example, California quail, mourning dove, and barn and cliff swallows (*Hirundo rustica* and *H. pyrrhonota*) all require daily water and are known to use ponds as water sources. The tricolored blackbird relies on vegetation associated with ponds (cattails and bulrush) for nesting. Many covered species, including California tiger salamander, California red-legged frog, and western pond turtle, use ponds as essential habitat; western pond turtle can be found inhabiting perennial ponds year-round and nesting in adjacent upland habitat during the nesting period. Ponds that contain either submerged or emergent vegetation are of particular importance to native amphibians as breeding habitat, although in ponds with little or no vegetation, California tiger salamander females may attach eggs to objects, such as rocks and boards on the bottom (Jennings and Hayes 1994). In perennial ponds, nonnative bass (*Micropterus* spp.) and bullfrog (*Rana catesbeiana*) are common and are often prevalent wildlife species. Bass and bullfrog are known to prey on special-status California red-legged frog and California tiger salamander and, as such, the presence of bullfrogs and bass limits the opportunity for success of these covered species.

Percolation ponds have minimal habitat values due to their location in urban areas. Percolation ponds require aggressive maintenance to maintain percolation capacity and preserve groundwater recharge for the water supply. Ponds with wetland fringe habitat (i.e., emergent vegetation) provide potential habitat for western pond turtle, California red-legged frog, and California tiger salamander. Most percolation ponds have only marginal habitat value for the covered species.

Reservoirs support several gull species as well as raptors that fish out of the lake and often nest in tall trees nearby. Shore and wading birds including killdeer, black-necked stilt, greater yellowlegs, and several gull species are found in and at the edges of reservoirs within the study area. Reservoirs provide habitat for some native fish such as hitch, Sacramento blackfish, California roach, and Sacramento sucker, but favor nonnative fish such as bluegills, sunfish, brown bullheads, carp, goldfish and largemouth bass. Reservoirs can also provide suitable rearing habitat for non-migratory rainbow trout if conditions are favorable. Reservoirs also promote the presence of nonnative fish in the watershed by providing suitable habitat. Nonnative fish often prey on native fish; for example, largemouth bass may prey on juvenile steelhead trout (Santa Clara Basin Watershed Management Initiative 2003).

Covered species found within the open water community include Bay checkerspot butterfly (for movement), California tiger salamander, California red-legged frog, western pond turtle, and tricolored blackbird.

## Open Water Land Cover Types

### Ponds

*Ponds* are small (less than 20 acres) perennial or seasonal water bodies with little or no vegetation. If vegetation is present, it is typically submerged or floating. Ponds may occur naturally or may be created or expanded for livestock use (stock ponds). All ponds discernible on aerial photographs were mapped.

Ponds were easily discernible on the basis of two distinctive aerial photograph signatures. One signature—smooth, uniform, and dark black—indicates deeper and less turbid ponds. The other signature—light gray-brown—generally indicates a shallower or more turbid pond. The latter signature was more difficult to discern on the aerial photographs and in some cases required field verification or corroboration with other wetland mapping (e.g., National Wetland Inventory). Where discernible, this land cover type was mapped to the high water line. Some wetland land cover types were likely included as ponds if vegetation was sparse or not visible on photos. The minimum mapping unit was 0.25 acre.

Off-stream groundwater recharge ponds, (commonly referred to as *percolation ponds*) are used in the study area in the following locations (Santa Clara Basin Watershed Management Initiative 2003):

- along Los Gatos Creek downstream of Lexington and Vasona Reservoirs;
- along Alamitos Creek, Guadalupe Creek, and the Guadalupe River downstream of Almaden, Calero, and Guadalupe Reservoirs;
- along Coyote Creek downstream of Anderson Reservoir; and
- along Llagas Creek downstream of Chesbro Reservoir.

Percolation ponds are located at sites where gravels and sands have been naturally deposited at or near ground level and where water can soak down most easily into the aquifer(s) (Santa Clara Valley Water District 1978 as cited in Santa Clara Basin Watershed Management Initiative 2003). These ponds are designed to allow infiltration of water at specified rates and must be cleaned out periodically when fine sediments build up, impeding percolation. These off-stream ponds are filled in the winter months with natural flow from rainwater. During the drier months, the SCVWD augments groundwater recharge in percolation ponds with imported water, including water from the Central Valley Project (Santa Clara Basin Watershed Management Initiative 2003).

Stock ponds are also used throughout the study area to provide water to grazing livestock. Lands historically used for grazing, but currently protected as open space, also contain old stock ponds that may be in disrepair. One example is in Henry W. Coe State Park where many stock ponds still exist (A. Palcovik pers. comm.). Many of these ponds currently support California red-legged frog or California tiger salamander. Park managers have reclaimed some ponds, returning them to a more natural state. Pond reclamation typically includes removal of the dam. The result is a shortened or eliminated hydroperiod of standing water, which may reduce the habitat value for covered species.

Pond vegetation is influenced by surrounding land use, livestock and wildlife activity, and site soil and hydrology. Plants often associated with ponds include floating plants such as duckweed (*Lemna* spp.) or rooted plants such as cattails, bulrushes, sedges, rushes, water cress, and water-primrose. Stock ponds are often surrounded by grazing land with grazing livestock. Immediately adjacent to the stock pond, soil may be exposed due to the continued presence of livestock or wildlife (e.g., feral pigs). As a result, many stock ponds are devoid of vegetation. Covered species, such as California tiger salamander may still use this habitat for breeding. Females may attach eggs to objects, such as rocks and boards on the bottom (Jennings and Hayes 1994). Stock ponds, removed from grazing pressures or excessive wildlife activity, may be surrounded by wetland vegetation including willows, cattails, reeds, bulrushes, sedges, and tules (*Schoenoplectus* [*Scirpus*] *californicus*) if the appropriate soil and hydrology is also present. Land uses surrounding percolation ponds may vary depending on the location of the pond. Percolation ponds are often found in more urbanized areas; therefore, the vegetated buffer may be narrower than it would be in a natural setting or managed for weed abatement.

Ponds are scattered throughout the study area, with the heaviest concentrations in the southeast corner of the study area, away from urbanized areas. **Figure 3-13** depicts the distribution of pond density in the study area. There are an estimated 716 ponds that occupy approximately 1,110 acres (0.2%) of the study area (**Table 3-7** and **Figure 3-10**).

Several species covered by this Plan can be found in or using ponds including California tiger salamander, California red-legged frog, western pond turtle, and tricolored blackbird. Bay checkerspot butterfly may pass over ponds on their way to habitat patches.

### Reservoirs

*Reservoirs* are large open water bodies, greater than 20 acres that are highly managed for water storage, water supply, flood protection, or recreational uses. These features were easily targeted on aerial photographs based on the smooth, uniform, dark signatures of open water. Where discernible, reservoirs were mapped to the high water line. The high water line was observed on the aerial photographs as either obvious rings of sparse vegetation or an open water signature.

Plants often associated with reservoirs include those plants common to deep water systems. Algae are the predominant plant life found in the open waters of reservoirs. Depending on reservoir temperature, water level, and other environmental conditions, algal blooms may occur, resulting in thick algal mats on the surface of the reservoir. If the reservoir edges are shallow, plant species similar to those found in ponds may be present. If the reservoir has steeper edges, water depth and fluctuations in reservoir height may prevent the establishment of vegetation. Upland and riparian trees that were not removed during the construction of the reservoir, or that were planted afterwards, may be present around the perimeter of the reservoir. Fluctuations in water levels may also affect the type of shoreline habitat that occurs around reservoirs (Santa Clara Basin Watershed Management Initiative 2003). The upstream end of several

reservoirs including Coyote Reservoir support large and important stands of riparian forest and woodland (these areas were mapped as riparian woodland).

Surrounding land uses at reservoirs vary depending on the location of the reservoir and the land cover type present in the area prior to reservoir development. Reservoirs are dispersed throughout the study area. Vasona, Guadalupe, and Almaden Reservoirs are located on the western border of the study area. Calero, Chesbro, and Uvas Reservoirs are located in the foothills of the Santa Cruz Mountains, west of Coyote Valley, Morgan Hill, and San Martin. Anderson and Coyote Reservoirs are located in the foothills of the Diablo Range, east of Morgan Hill and San Martin. Pacheco Reservoir is located in the southeast corner of the County, north of SR 152. Reservoirs occupy approximately 2,767 acres (0.6%) of the study area in 18 locations (**Table 3-7** and **Figure 3-10**).

Species covered by this Plan that may be found living in or using reservoirs are western pond turtle and tricolored blackbird.

## Ecosystem Functions

### Function and Integrity

Open water land cover types perform a variety of functions in both biological and physical terms. Biologically, water is the most critical component required to support the lifecycle of all aquatic and terrestrial species. Open water land cover types support the species at the lowest level of the food chain, algae. Aquatic invertebrates feed on algae and other plant debris in creeks, ponds, and reservoirs. In turn, these invertebrates become food for fish, birds, bats, and other insect-feeding species. The cycle continues, supporting species of the highest trophic levels including coyotes, mountain lions, and humans.

Ponds enhance all other habitats in terms of value for wildlife. Mammals, birds, reptiles, and amphibians from adjacent habitats are likely to use ponds en route to surrounding areas (Santa Clara Basin Watershed Management Initiative 2003). Many upland species rely on streams and ponds as water sources, especially during the dry summer months.

Percolation ponds, while often seasonally stable in water level, are highly manipulated and provide varying degrees of habitat value. While emergent vegetation frequently develops along the shoreline of percolation ponds, the buffer zone between these emergent wetlands and adjacent urban land uses, such as parks or housing, limit wildlife access and use of these ponds by mammals, amphibians, and reptiles. While birds maintain access to percolation ponds, human activity and domestic pets around the shoreline limit nesting by waterfowl and other birds (Santa Clara Basin Watershed Management Initiative 2003). Periodic maintenance of percolation ponds can interrupt aquatic system functions, resulting in the loss of those primary food chain constituents such as detritus, algae, and emergent vegetation.

Reservoirs are sediment sinks, obstructing the natural sediment transport of streams. Through natural processes, streams erode sediment from stream banks and move it down stream. In an unimpeded setting, sediment carried from the upper watershed is deposited along the length of the stream, thus creating an equilibrium of eroded and deposited sediment. When a dam is built across a stream, all but some of the finest sediment transported from the upper watershed drops out of suspension in the reservoir, where velocities are too low to maintain the sediment load. The resulting effect is that downstream reaches are sediment-starved, and no new sediment is available to replace eroded sediment downstream of the dam. This results in the stream downcutting and deepening and also results in a reduction in gravels downstream of reservoirs. In addition, large reservoirs fill with and store large amounts of turbid storm runoff. Settling of the finer clay and silt particles may take months, resulting in persistent releases of turbid water in winter and early spring. The slowly settling materials may also result in much higher turbidities near the bottom outlet valve than in the surface waters. While the natural streams upstream of reservoirs rapidly clear between storms, the streams downstream of reservoirs may be persistently turbid. In addition, the slowly released fine sediments may result in silty substrate below the reservoirs, reducing abundance of insects. During parts of the year, the reservoir conditions may produce bioturbidity from organic production in the water column. Turbidity can also be caused by bio-productivity in the water column, which may affect the efficiency of visual feeding organisms.

Reservoirs disrupt the natural flow cycle of streams. In addition, because the reservoirs are deep and store cool winter runoff, the water released out of the bottom of the reservoir can be much cooler than the surface water and also cooler than the stream upstream of the reservoir in late spring and summer.

### **Natural Disturbance**

The role of disturbance in open water land cover types focuses on the mixing of water from the surface to the bottom. Wind contributes heavily to mixing of water in ponds and lakes. Mixing brings oxygen to the bottom of ponds and lakes while releasing nutrients into the water column that will feed plants and invertebrates. Disturbances to standing water bodies often relate to *eutrophication*, the natural processes by which excessive nutrients are deposited into the water body, stimulating plant growth. This rapid plant growth, often referred to as an *algal bloom*, reduces dissolved oxygen in the water as anaerobic microbes break down dead plant material. Reduced levels of dissolved oxygen, as well as reduced penetration of sunlight into the water, often lead to the die-off of other aquatic organisms. Eutrophication eventually leads to the filling in of the water body. Both ponds and reservoirs are susceptible to rapid eutrophication. In urbanized areas, or in areas with septic tanks or grazing livestock, this process is enhanced by excess nutrient input. Oxygen-depleting algal blooms may lead to fish kills.

Reservoirs may also suffer from a lack of mixing surface waters with water at deeper depths. Mixing distributes oxygen to the reservoir floor, preventing anaerobic conditions that may reduce the dissolved oxygen in the reservoir. Maintaining appropriate levels of dissolved oxygen is important for aquatic life in the reservoir and downstream of the reservoir, as well as for drinking water

supplies. Dissolved oxygen levels are also affected by water temperature. Warmer water contains lower levels of dissolved oxygen.

### Threats

Open water land cover types are threatened by pollution; livestock disturbance, including trampling and excessive nutrient inputs leading to rapid eutrophication; high water flows which cause erosion; habitat destruction; and unnatural channel modification resulting from the need to contain flows. The manipulation of otherwise natural processes (flooding, natural stream meandering) changes the ecosystem function of aquatic communities and generally reduces overall biodiversity and native survivorship by eliminating a dynamic component of the ecosystem. The various open water land cover types have different primary threats, as described below.

Pond breaching, berm failure, livestock and wildlife impacts, including feral pigs, and inadequate management practices can increase soil erosion and result in increased sedimentation of the pond (Hamilton and Jepson 1940; Prunuske 1987). This reduces habitat quality for amphibian habitat. Alternatively, ponds with insufficient turbidity provide inadequate cover for California tiger salamander larvae (69 FR 47216). Heavy livestock and excessive wildlife use (e.g., feral pigs) use can degrade ponds quickly, leading to loss of emergent vegetation and eutrophication from increased nitrogen due to cattle urine. High flows cause erosion, unless fully cemented channels are in place. To control flooding, channels are modified in an unnatural way (i.e., placement of rip rap, lined with concrete) and results in a decrease of riparian vegetation and aquatic habitat for fish and other species. Some cities are working to address this issue. For example, the City of San José requires that riparian vegetation be avoided during construction activities, and if it cannot be avoided, mitigation is required. Mitigation requires replacement of riparian vegetation and/or compensation for any adverse affects to creeks (City of San José 2005). Additionally, pollution sources along the channels can degrade water quality within riverine systems.

## Irrigated Agriculture

Irrigated agriculture encompasses all areas where the native vegetation has been cleared for irrigated agricultural use. This natural community does not include rangeland, which is often characterized as an agricultural land use. The irrigated agriculture community is classified into four land cover types.

- Orchard.
- Vineyard.
- Agriculture developed.
- Grain, row-crop, hay and pasture, disked/short-term fallowed<sup>19</sup>.

In all of these cases, the land may have been irrigated in the past but show little or no sign of irrigation currently (e.g., fallow fields). In some instances these

<sup>19</sup> This land cover type may or may not be irrigated.

land cover types were indistinguishable on aerial photographs (e.g., newly planted orchards strongly resemble row crops). In such cases the area in question was mapped as grain, row-crop, hay and pasture, and disked/short-term fallowed.

## Historical Extent and Composition

Father Junípero Serra gave Santa Clara Valley its name when he consecrated the Mission Santa Clara de Asís in 1777 (National Park Service 2006). The establishment of the mission also heralded the beginning of large-scale agriculture in the Santa Clara Valley. Soon, the Guadalupe River dam (located near Mission Santa Clara) was constructed for irrigation of wheat, corn, bean, and other crops. Fruit trees and grapes were also cultivated. Settlers' accounts during 1850 describe the whole plain of Alameda County to San José as a vast unfenced field of grain (Santa Clara Basin Watershed Management Initiative 2003).

The Santa Clara Valley has experienced continued population growth since 1850. By 1866, artesian wells could no longer meet water demands. In 1870, Los Gatos Creek was diverted in order to meet the water demands for agriculture and a booming population (Santa Clara Basin Watershed Management Initiative 2003). Agricultural success in the Santa Clara Valley was supported by access to railroads that could take goods to port. Large aquifers were also discovered underlying the valley and were tapped by artesian wells. These two factors bolstered a rapid increase in agriculture in the region. The area produced carrots, almonds, tomatoes, prunes, apricots, plums, walnuts, cherries, and pears for the world market (National Park Service 2006). In 1870, seed farms became another dominant form of agriculture in the valley. Other agricultural commodities harvested from the Santa Clara Valley included lumber and grapes for wineries (National Park Service 2006).

By 1930, there were 120,000 acres of orchards in production (Santa Clara Basin Watershed Management Initiative 2003). The Santa Clara Valley remained largely rural and agricultural, supporting farms, orchards, wineries, and ranches until after World War II (National Park Service 2006). Due to an increased demand for urban services, there was a one-third reduction in the amount of cultivated lands between 1947 and 1961 (Santa Clara Basin Watershed Management Initiative 2003). Despite these changes, the South Valley in Santa Clara County continues to support rural homesteads and agriculture.

## Common Wildlife Associations

Some native wildlife, such as small mammals, certain raptors, and migratory waterfowl, utilize irrigated agriculture seasonally or year-round. Year-round activity tends to be concentrated along the margins of active farmland where vegetation is less disturbed or where trees and shrubs tend to occur (some are planted deliberately as windbreaks). Open fields that are irrigated for forage crops are also used by wildlife. Cultivated agriculture is bisected by streams,

ditches, and channels. Some amphibians and reptiles utilize these linear aquatic features and the adjacent upland habitat.

Orchard and vineyard fruits attract common wildlife species such as scrub-jay, European starling (*Sturnus vulgaris*), western tanager (*Piranga ludoviciana*), Brewer's blackbird, American crow, yellow-billed magpie (*Pica nuttalli*), raccoon, opossum, California vole, and coyote. Orchards and vineyards that are not plowed provide foraging, cover, and denning sites for native gray fox and nonnative red fox (*Vulpes vulpes*), burrowing owl, California ground squirrel, and various gophers, mice, and snakes (Santa Clara Basin Watershed Management Initiative 2003). Insects are important pollinators of blossoms to ensure fruit. Owls and other raptors such as white-tailed kite, red-shouldered hawk, red-tailed hawk, and burrowing owl feed on rodents and insects found in orchards and vineyards. Old buildings and barns may provide shelter for bats and owls (Santa Clara Basin Watershed Management Initiative 2003).

Data collected in Sonoma County indicate that vineyards generally support a far higher abundance of nonnative predators such as red fox and feral cats than do adjacent natural habitats (Hilty and Merenlender 2004). Other common wildlife species found in most vineyards include California ground squirrel, European starling, and Brewer's blackbird. As in other forms of agriculture, site-specific production methods are directly correlated with wildlife use. Some vineyard practices may encourage habitat use by birds of prey such as American kestrel and great horned owl (Locke 2002). Wildlife use of vineyards may be related to the timing and intensity of pesticide application with heavy pesticide use decreasing wildlife use and reproductive success.

Dryland crops are usually established on fertile soils that have historically supported a variety of wildlife (Mayer and Laudenslayer 1988). Although grain cropland cover supports reduced wildlife habitat richness and diversity for native species, it does support a greater variety of wildlife species than traditional irrigated agricultural land cover (e.g., vineyards and orchards). Short-grass habitat associated with dryland grain production is compatible with foraging by raptors such as western burrowing owl. During winter, this type of agricultural land also provides important foraging and roosting habitat for wintering waterfowl.

Pastures support a variety of wildlife, particularly ground-nesting birds such as western meadowlarks (*Sturnella neglecta*). Irrigated pasture, particularly alfalfa, can provide a variety of wildlife benefits due to its relatively high production of small rodents. Several birds that forage in open grasslands, such as white-tailed kites and great blue herons, may also use this land cover type.

## **Irrigated Agriculture Land Cover Types**

### **Orchard**

*Orchards* are those areas planted in fruit-bearing trees. Orchard was distinguished on the basis of its tree cover, canopy characteristics, and distinctive production rows. In Santa Clara County, orchards mostly include apricots,

cherries, prunes, and walnuts (County of Santa Clara, Department of Agriculture 2004).

Orchards comprise an estimated 2,697 acres (0.06%) of the study area (**Table 3-7** and **Figure 3-10**). Orchards are scattered in relatively small patches throughout the Santa Clara Valley floor from the southern point of San José south to the county line. The largest patch of orchard is found in Coyote Valley in the area designated as the Coyote Greenbelt. Small orchards are also present south of Highway 130 in the Diablo Range foothills.

Some covered species may be found in orchards. For example, where natural open spaces abut, some individuals of San Joaquin kit fox may forage in and disperse through orchards. Western burrowing owl may forage in and move through orchards. Tricolored blackbirds may move through and/ or forage in and over orchards. Bay checkerspot butterfly, California red-legged frog and California tiger salamander may migrate through orchards between areas of suitable habitat. Western pond turtle may nest along the open margins of orchards, particularly if situated adjacent to suitable aquatic habitat (**Table 3-5**).

### **Vineyard**

*Vineyard* was identified on the basis of its row production pattern and canopy characteristics. Vineyards appeared similar to orchards on the aerial photographs but were characterized by more closely spaced rows with a smaller, less dense vegetation canopy.

Vineyards occupy 1,393 acres (0.3%) of the study area (**Table 3-7** and **Figure 3-10**). Vineyards are mostly located in the southern portion of the county, in the foothills west of San Martin, along Uvas Creek and its tributary Little Arthur Creek, and along SR 152 east of Gilroy. Similar covered species are expected to be found in vineyards as in orchards, with the exception of burrowing owl (**Table 3-5**).

### **Agriculture Developed**

*Agriculture developed* was identified by the presence of large agricultural buildings such as greenhouses, shadehouses, nurseries, corrals, or dairies. These intensive uses were found within agricultural areas rather than urban settings. Air photo signatures were generally distinctive because of their large agricultural structures or high densities of livestock.

This land cover type occupies 1,935 acres (0.4%) of the study area in small patches scattered throughout the Santa Clara Valley from Coyote Valley to the county line (**Table 3-7** and **Figure 3-10**). Covered species that may be found in this land cover type include western burrowing owl (e.g., in some of the larger corrals that may be less intensively used), tricolored blackbird, and migrating Bay checkerspot butterfly and San Joaquin kit fox (**Table 3-5**).

### **Grain, Row-Crop, Hay and Pasture, Disked/Short-Term Fallowed**

Tilled land not appearing in the aerial photographs to support orchard or vineyard was mapped as grain, row-crop, hay and pasture, disked/short-term fallowed.

*Grain, row-crop, hay and pasture, disked/short-term fallowed* is the most

common of the agriculture land cover types in the low-lying areas of the study area, occupying 33,648 acres (7.3%) of the study area (**Table 3-7** and **Figure 3-10**). These lands are abundant throughout the Santa Clara Valley south of San José, and are most dense just north of the southern county border.

*Row-crops* are those areas tilled and cultivated for agricultural crops such as corn, lettuce, peppers, and pumpkins. *Fallow fields* include fields that were not in production at the time aerial photos and/or site visits were conducted, but may be utilized for grain, row-crops, and hay and pasture in subsequent years. This land cover type includes ruderal areas that had been left fallow for several growing seasons. Ruderal sites may be dominated by weeds such as black mustard or thistles.

*Hay and pasture* include both dryland settings and irrigated areas. The key difference between hay production and pasture is that crops are harvested on site and consumed off site, whereas pasture is consumed by livestock on site (hay is also cut, baled, and trucked off site). In addition to production for consumption, hay is also produced in Santa Clara Valley for grain. The pasture land cover type consists of fast-growing annual and perennial grasses mixed with irrigated forage crops in the legume family. Pastures typically function as onsite sources of forage for livestock. These areas are distinguished from other cultivated land types by the presence of livestock and livestock fencing (paddocks). Pastures tend to occur in lowland areas adjacent to cropland. Pasture was mapped on aerial photographs based on its location and smooth texture on the photographs, indicating land that is covered by vegetation and not currently tilled for cropland.

Common vegetation includes fast-growing forage grasses, such as wild oats and Italian ryegrass, as well as irrigated legumes such as alfalfa (*Medicago sativa*), sweet clover (*Melilotus* spp.), and true clover (*Trifolium* spp.). In some areas, nonnative weedy vegetation, such as thistles, mustards, and a variety of other weedy forbs, are also common.

Covered species expected to be found in this land cover type are tricolored blackbird, and western burrowing owl all of which forage in grain crops and pastures (**Table 3-5**). Tricolored blackbird and western burrowing owls may also breed in agricultural settings. San Joaquin kit fox may move through this land cover type if it occurs near suitable grassland areas. California tiger salamander, California red-legged frog, and western pond turtle move through croplands to reach suitable breeding and aestivation habitat. Bay checkerspot butterfly migrate through these habitats between patches of serpentine grassland.

## Ecosystem Functions

### Function and Integrity

This land cover type has relatively low value for native plants and wildlife in terms of habitat that supports full lifecycle needs. Nonetheless, agriculture does provide some benefit, although species composition depends heavily on the planting cycle. For example, cropland has a higher value for terrestrial mammals (e.g., black-tailed jackrabbit) and herbivorous birds (e.g., red-winged blackbird)

near harvest time, when the standing crop is mature and produces a quantity of food (e.g., fruit, seeds), than it does after the harvest when the cropland is fallow. Agricultural production methods can also have an impact on wildlife use. For example, production practices such as *clean farming*, where farm edges are maintained as vegetation-free areas, reduce cover and movement opportunities for wildlife; on the other hand, *wildlife friendly farming*, where native cover crops and hedge rows are used between crops and on farm edges, can increase opportunities for wildlife use in croplands.

In addition, agricultural lands often play a key role in providing connectivity between larger open space areas, especially in urbanizing areas such as the Santa Clara Valley. Maintaining connectivity between open space patches that provide habitat supports a diversified genetic pool due to the ability of populations to disperse and co-mingle. Agriculture also often is associated with streams, canals, and ditches used for irrigation that may support riparian vegetation, trees (planted as windbreaks), and shrubs. These areas may provide habitat to songbirds, raptors, amphibians and reptiles, as well as provide a movement corridor for other species.

### **Natural Disturbance**

Disturbances common to cropland, orchards, and vineyards relate to the standard operations of farming practices. Seasonal tilling, planting, and harvesting prevent the long-term establishment of plants or animal burrows on this land. Management practices also usually include the application of pesticides, discouraging the establishment of plants or presence of wildlife. Furthermore, offsite drift may harm wildlife or plants in adjacent open space areas.

### **Threats**

Orchards, vineyards, and row-crops are often found in areas of low to moderate topographical variation—areas such as valley floors or foothills. In these areas, the major threat to irrigated agriculture is land conversion to urban uses, often as residential housing.

## **Developed**

Developed land cover types were mapped and described for the study area in order to describe the extent and distribution of modified lands. Developed areas were classified into the land cover types listed below.

- Urban-suburban.
- Rural-residential.
- Barren.
- Landfill.
- Golf courses/urban parks.
- Ornamental woodland.

Developed land cover types were mapped on the basis of their distinct signatures on aerial photographs and are readily distinguishable from naturally occurring signatures in any terrain. The minimum mapping unit for all developed land cover types was 10 acres.

## Common Wildlife Associations

Developed, or urban, areas tend to support a low diversity of wildlife (Dickman 1987; Gilbert 1989). However, what species do exist in urban areas tend to be present at greater concentrations than is typical of other habitat types (Gilbert 1989). A limited number of mostly nonnative species such as dogs, cats, house mice, Norway brown rats, pigeons, European starlings, and opossums thrive in urbanized habitats in the study area (Santa Clara Basin Watershed Management Initiative 2003).

Several species are common to urban areas, including a variety of bird species that adapt well to urban landscapes. Typical bird species found in the urban landscape include the American robin (*Turdus migratorius*), mockingbird (*Mimus polyglottos*), American crow (*Corvus brachyrhynchos*), and European house sparrow (*Passer domesticus*). These species are typically generalized opportunistic foragers that are highly tolerant of human activity. Few special-status avian species occur in urban areas, however, there are some notable exceptions. As discussed below, western burrowing owl, covered in this Plan, may be found in ruderal or barren remnant patches in urban areas. Peregrine falcons (*Falco peregrinus*) are found even in downtown San José, where one pair nested in 2006. In 2006 a colony of approximately 200 red-winged blackbirds and tricolored blackbirds was documented during field work for this project using the southern fringe of a pond located adjacent to U.S. 101 in a vacant lot in Morgan Hill.

Some wildlife species are abundant in the ruderal areas of agricultural sites where there is no disturbance from tilling and pest control measures. This is especially true for burrowing mammals such as California ground squirrels. Western fence lizards and gopher snakes, which often use mammal burrows for cover, are also more common in these urban areas. Other common wildlife found in urban areas include rodents, grey squirrel, opossum, raccoon, and skunk. Other wildlife, once less common in urban areas but now on the rise across the country, include deer, coyote, and wild turkeys.

Ornamental woodlands, including eucalyptus stands, are occasionally planted as wood lots or shelter belts. The overall wildlife value of ornamental woodlands is highly variable and depends on the species planted. For example, eucalyptus trees provide night roosts, foraging perches, and nest sites for a few bird species, particularly raptors. Eucalyptus bark peels can create microhabitats for some small vertebrate species, such as alligator lizards and woodrats (Santa Clara Basin Watershed Management Initiative 2003).

## Developed Land Cover Types

*Developed areas* comprise all types of development for residential, commercial, industrial, transportation, landfill, landscaping, and recreational uses (e.g., sites with structures, paved surfaces, horticultural plantings, golf courses, and irrigated lawns). Developed sites were mapped on the basis of their distinct signatures on aerial photographs. Developed areas are often characterized by geometric or regular shapes, and are readily distinguished from naturally occurring signatures in any terrain. This category was separated into six land cover types: urban-suburban, rural residential, barren, landfill, golf courses/urban parks, and ornamental woodland.

### Urban-Suburban

The *urban-suburban* land cover comprises areas where the native vegetation has been cleared for residential, commercial, industrial, transportation, or recreational structures, and is defined as one or more structures per 2.5 acres. These include areas that have structures, paved and impermeable surfaces, horticultural plantings, and lawns smaller than 10 acres (irrigated lawns larger than 10 acres were mapped as urban parks). Many small, rural residential areas were observed in the inventory area. Such areas were mapped as urban if they exhibited at least 10 acres of buildings, turf, and pavement. Rural residential areas of less than 10 acres that were adjacent to or surrounded by agriculture and/or natural land cover types were mapped as the adjacent land cover type. Parcels of non-urban land cover types within the study area on which development projects were already approved were mapped as urban-suburban.

Vegetation found in the urban-suburban land cover type is usually in the form of landscaped residences, planted street trees (i.e., elm, ash, liquidambar, pine, palm), and parklands. Most of the vegetation is composed of nonnative or cultivated plant species. One invasive nonnative tree, the tree-of-heaven, has become established in yards and vacant lots in the City of San José area (Santa Clara Basin Watershed Management Initiative 2003).

The major urban-suburban area in the study area is San José, located in the northern portion of the Santa Clara Valley. Other urban-suburban areas include areas within Morgan Hill and Gilroy. Urban-suburban areas comprise 89,438 acres (19.4%) of the study area (**Table 3-7** and **Figure 3-10**).

It is unlikely that any covered species would be found in urban-suburban areas; however, Bay checkerspot butterfly may migrate across urban-suburban areas (i.e., parking lots) between patches of serpentine grassland. Still, this land cover type is largely characterized by impermeable surfaces and extreme hazards to wildlife that provide no habitat value.

### Rural Residential

The *rural residential* land cover type is similar to the urban-suburban type except that it is typically much less dense (defined as less than 1 structure per 2.5 acres) and usually contains extensive landscaping and/or irrigated lands (including small areas of pasture).

Rural residential areas are mainly located in the foothills along the eastern edge of San José, at the southern point of San José near Almaden Quicksilver County Park and Santa Teresa County Park, and south of Morgan Hill and north of Gilroy. Rural residential areas comprise 12,414 acres (2.7%) of the study area (**Table 3-7** and **Figure 3-10**).

Several covered species may be found in rural residential areas. Species such as California red-legged frog, western pond turtle, western burrowing owl, tricolored blackbird, or San Joaquin kit fox may move through rural residential land cover if it occurs adjacent to or near open space. Bay checkerspot butterfly will move through rural residential areas to disperse between patches of serpentine grassland. Rural residential areas that contain small patches of serpentine soils may be used by dispersing Bay checkerspot butterflies as temporary foraging sites.

### **Barren**

*Barren* land cover types are non-agricultural areas that have been historically and recently disturbed. Land uses in this type include aggregate facilities and mine tailings. Barren land use types are uncommon throughout the study area. Barren land use types comprise only 211 acres (0.05%) of the study area in 6 locations.

While barren landscapes do not provide high quality for most covered species, this land cover type is often suitable for foraging and breeding western burrowing owls (**Table 3-5**). San Joaquin kit fox and tricolored blackbird may move through and/or forage in barren areas. California tiger salamander, California red-legged frog and Bay checkerspot butterfly may migrate through barren areas between habitat patches.

### **Landfill**

*Landfills* are those areas where vegetation has been cleared and large amounts of soil have been moved for solid waste disposal. Typically, these areas are excavated pits into which refuse is placed and compacted. After a landfill is closed and capped, it may be returned to natural habitats through planting and management. Only active landfills were mapped in this category.

There are three landfills within the study area: San José's Guadalupe and Kirby Canyon landfills, and a landfill east of Gilroy. The Guadalupe landfill is located on the border of the study area; it has a 411-acre permitted facility boundary and a 115-acre permitted disposal area. Eighty-eight acres of this facility (21%) is inside the study area. The Kirby Canyon landfill has a 760-acre facility boundary and a 311-acre disposal area, all of which is in the study area. The Gilroy landfill is approximately 82 acres.

Landfills were mapped as occurring on 364 acres (0.02%) of the study area (**Table 3-7** and **Figure 3-10**). The difference in mapped acreage and locally-approved boundaries indicates that the landfills are expected to expand in the future.

Landfills are highly disturbed areas while in use. They often attract some wildlife such as gulls, crows, pigeons, and rats. The only covered species that

may be found in landfill areas is Bay checkerspot butterfly as it migrates between suitable habitat patches.

### **Golf Courses/Urban Parks**

Urban parks are located within cities in the study area and tend to be smaller in scale than a county or regional park. Many serve as neighborhood or community parks.

*Urban parks* and *golf courses* are located throughout the urbanized areas of the study area. Urban parks and golf courses comprise 8,673 acres (1.9%) of the study area (**Table 3-7** and **Figure 3-10**).

Golf courses and urban parks provide limited habitat for native wildlife. Urban parks are unlikely to support any covered species. Golf courses on the fringe of urban areas are known to support California tiger salamander, California red-legged frog, western pond turtle, western burrowing owl, San Joaquin kit fox or tricolored blackbird, particularly if ponds are present on or near the golf course (**Table 3-5**). Bay checkerspot butterfly may migrate through this land cover type between habitat patches.

### **Ornamental Woodland**

*Ornamental woodlands* are those areas where ornamental and other introduced species of trees, including Eucalyptus, have been planted or naturalized and dominate, forming an open to dense canopy.

Ornamental woodland was mapped primarily in areas surrounded by development, where the signatures on aerial photographs and locations did not meet the characteristics of oak or riparian woodlands. Ornamental woodland was included as a separate land cover type because some stands could provide suitable habitat for raptors. The ornamental woodlands land cover type comprises only 95 acres (0.02%) of the study area (**Table 3-7** and **Figure 3-10**).

While ornamental woodland land cover does not provide appropriate habitat for most covered species, this land cover type may support breeding raptors.

**Table 3-4.** Uncertainties in Land Cover Mapping, by Land Cover Type

Land Cover Type	Comment	General Mapping Confidence <sup>1</sup>
<b>Grassland</b>		
California annual grassland	Almost always has a distinct signature, may be difficult to distinguish from some seasonal wetlands.	High
Serpentine bunchgrass grassland	As for California annual grassland. Uncertainty lies with available serpentine soils and geology mapping, from which this land cover was derived (see text).	High
Serpentine rock outcrop	Likely under-mapped because outcrops are generally small and below the minimum mapping unit of 0.25 acres; outcrops below a chaparral or woodland canopy would be missed.	Low
Serpentine seep	Could be difficult to distinguish if seep is seasonal (i.e., not perennial) and therefore would appear similar to surrounding grasslands on December aerial photograph.	Moderate
Rock outcrop	As for serpentine rock outcrop.	Low
<b>Chaparral and Northern Coastal Scrub</b>		
Northern mixed chaparral /chamise chaparral	Generally quite distinct; the main issue in mapping was the distinction with adjacent mixed oak or foothill pine-oak;- there was often a gradation rather than a distinct difference in signatures among these land cover types. This occurred mainly in the northeast and east portions of the study area where chaparral on south-facing slopes graded into mixed-oak woodland in drainages and on north-facing slopes with intermediate areas of taller chaparral and lower-stature oak. At times it was difficult to judge the height of vegetation on slopes from the photos.	High
Mixed serpentine chaparral	Clear signature, mapped where serpentine soils/rocks intersected with chaparral signature.	High
Northern coastal scrub/Diablan sage scrub	Northern coastal scrub dominated by California sagebrush had a distinctive pale green signature, but coastal scrub dominated by black sage appeared dark green and was similar in hue to chamise and to some of the components of mixed chaparral.	High
Coyote brush scrub	Dark green signature was similar to chamise and black sage; landscape position aided in distinguishing this uncommon type in the plan area.	Moderate
<b>Oak Woodland</b>		
Valley oak woodland	Main issue in mapping was distinguishing valley oak woodland from blue oak woodland. Valley oak trees typically appeared large-crowned, well-spaced, grayish (leafless) on the March 2003 photo, and were located on either broad ridge tops and shoulders or broad valley bottoms. Blue oak trees typically appeared smaller-crowned, closer-spaced, were beginning to leaf out in the March photos (earlier than valley oak), and were located on steeper, south, southwest, or southeast-facing slopes. Trees that appear intermediate in any of those characters were more difficult to classify, so large well-spaced blue oaks, denser stands of small-crowned valley oak, and blue oaks on valley bottoms were more likely to be mis-classified.	Moderate
Mixed oak woodland and forest	This type was characterized by a mix of deciduous and evergreen oaks; the two could be distinguished on the December 2003 or 2005 photographs when the deciduous trees were leafless; on the March 2003 photo, when the deciduous trees were in leaf, Mixed oak appeared similar to Coast live oak woodland. Because this type generally graded into the adjacent types with no clear distinction, the main issue was deciding where to separate the different types. Topography was helpful.	Moderate

Land Cover Type	Comment	General Mapping Confidence <sup>1</sup>
Blue oak woodland	See comments under Valley oak woodland. Blue oak woodland is much more abundant than Valley oak woodland, so errors in attributes would have greater effects on the Valley oak woodland land cover type than blue oak woodland.	High
Coast live oak forest and woodland	See comments under Mixed oak woodland and forest	Moderate
Foothill pine—oak woodland	The signature of foothill pine was usually distinctive. As discussed above, this type could grade into chaparral. December photos were taken at a time of day with pronounced shadows, which made isolated trees such as foothill pine easy to identify.	High
Mixed evergreen forest	Difficult to distinguish from Coast live oak woodland as both types are closed-canopy woodlands with similar dark green signatures. Geographic location was helpful – mixed evergreen occurred on the west side of the valley, while coast live oak woodland occurred throughout the plan area. Topography was somewhat useful – although both types occurred on north-facing slopes, Mixed evergreen was often in mid-slope positions while Coast live oak tended to be on the lower slopes.	Moderate
<b>Riparian Forest and Scrub</b>		
Willow riparian forest and scrub	Distinguished from Mixed riparian woodland by generally smaller stature trees and by the bright yellow appearance of small willows that retained their leaves into December; generally dominated by willow and lacking other species, such as bay and coast live oak, that would appear green in December photo, and alder, cottonwood, and valley oak, that would appear leafless in December. This type graded into Mixed riparian woodland, however, without a distinct boundary	Moderate-High
Central California sycamore alluvial woodland	Mature stands of sycamore had a distinctive signature in the December aerial, with the well-spaced large pale grayish crowns surrounded by a ‘halo’ of golden-yellow fallen leaves. Main difficulty in mapping was with large well-spaced cottonwood trees, which could appear similar to large sycamores, although the canopy was generally smaller. Land cover mapping for the HCP/NCCP was compared to field-based mapping conducted by CDFG (Keeler-Wolf et al. 1997) and found to be generally consistent (see text for more discussion).	Moderate-High
Mixed riparian forest and woodland	See comments under Willow riparian forest and scrub	Moderate-High
Riverine	Not mapped; using linear data sets provided by SCVWD.	N/A
<b>Conifer Woodland</b>		
Redwood forest	Mature redwood canopies were readily distinguishable; main confusion would be with Douglas-fir, which fieldwork revealed to be relatively uncommon (no large stands were observed); areas with regenerating redwoods could be confused with mixed evergreen forest.	Moderate-High
Ponderosa pine woodland	Very clear signature and restricted geographic distribution in the plan area made this a distinct type: ponderosa pine occurs on just 3 ridges with widely scattered tall trees casting distinctive long shadows on the surrounding grassland. However, small stands of ponderosa pine also occurred in some of the valley below the ridges, where they could be difficult to distinguish from the surrounding evergreen oak crowns.	High
Knobcone pine woodland	Restricted geographic and topographic distribution in the Plan but lacking a distinctive signature, mostly identified on the basis of geographic and topographic location (ridgetops in the extreme west of the plan area).	High

Land Cover Type	Comment	General Mapping Confidence <sup>1</sup>
<b>Wetland</b>		
Coastal and valley freshwater marsh	Generally had a distinct signature. Some freshwater marshes may have been below the minimum mapping unit of 0.25 acres. Photos from three seasons (winter 2003 and 2005, spring 2003) ensured that conditions were favorable to perennial marsh on one or more air photos.	Moderate
Seasonal wetlands	Color differences in seasonal wetlands were difficult to distinguish from a variety of surrounding land cover types, and resulted in a very small acreage of this land cover in the first draft of the maps. Many seasonal wetlands may occur at a scale below the minimum mapping unit of 0.25 acres. Subsequent mapping of seasonal wetlands using additional data sources (e.g., Coyote Valley Specific Plan and National Wetland Inventory data) have resolved some of the mapping uncertainties.	Low (Moderate <sup>2</sup> )
<b>Open Water (Aquatic)</b>		
Pond	Distinctive; main issue was visibility because of heavy shadows on the December photo when ponds were full.	High
Reservoir	Large, highly distinctive.	High
<b>Irrigated Agriculture</b>		
Orchard	Distinctive regular pattern of tree crowns; recently planted orchards could be confused with disked or fallow fields if the small trees were too small to be visible.	High <sup>3</sup>
Vineyard	Generally distinctive because of the narrow rows; recently planted vineyards could be confused with disked or fallow fields because the small vines were too small to be visible	High <sup>3</sup>
Agriculture developed	Distinctive	High <sup>3</sup>
Grain, row-crop, hay and pasture, disked/short-term fallowed	Distinctive; the main issue was more associated with the definition rather than recognition and was related to the separation of annual grassland and short-term fallow	High <sup>3</sup>
<b>Developed</b>		
Urban-Suburban	Distinctive	High <sup>3</sup>
Rural residential (<1 unit per 2.5 acres)	Distinctive	High <sup>3</sup>
Golf courses/Urban parks	Distinctive	High <sup>3</sup>
Landfill	Distinctive	High <sup>3</sup>
Ornamental woodland	Generally distinctive based on location and patterning of the tree crowns; many stands below minimum mapping unit of 10 acres but this is generally not important for the covered species.	Moderate <sup>3</sup>
Barren	Distinctive	High <sup>3</sup>
Notes:		
<sup>1</sup> Qualitative confidence in mapping in terms of accuracy of polygon boundaries, polygon attributes, and the extent of the land cover type in the study area (i.e., over- or under-mapped).		
<sup>2</sup> With supplemental mapping using additional data sets (see text under <i>Seasonal Wetlands</i> ).		
<sup>3</sup> See text and Tables 3-3a and 3-3b for quantitative error checking of agricultural and urban land-cover types. Quantitative error checking of natural land-cover types was not feasible.

## Chapter 4

# Impact Assessment and Level of Take

### 4.1 Introduction and Approach

This chapter addresses the effects of the covered activities described in Chapter 2 *Land Use and Covered Activities* on covered species and natural communities. Direct impacts are assessed quantitatively; indirect impacts are assessed qualitatively. The cumulative effects of projects in or near the study area and impacts on critical habitat are also analyzed.

The approach to analyzing impacts was by necessity a programmatic one. Because the Plan is large in geographic scope, broad in the range of activities covered, and long in terms of the duration, the impact assessment represents approximate impacts rather than precise numbers. Therefore, the acres of impacts presented in this chapter represent total impacts allowable under the Plan. Fees will be paid, in part, based on actual impacts to land cover types as determined during Plan implementation.

The impact analysis was based on the seven major categories of covered activities described in Chapter 2 and listed below.

- Urban Development.
- In-stream Capital Projects.
- In-stream Operations and Maintenance.
- Rural Capital Projects.
- Rural Operations and Maintenance.
- Rural Development.
- Conservation Strategy Implementation.

### 4.2 Definitions

The terms below are defined for the purposes of this Plan.

*Impacts* are those actions affecting biological resources, specifically undeveloped land cover types and covered species, in the permit area. Impacts can be direct or indirect; they can also be cumulative.

*Direct impacts* are defined as activities or projects that remove or alter land cover types, or covered species habitat, populations, or occurrences (or portions of thereof). Direct impacts are caused by the project and occur at the time and place of project implementation (e.g., ground disturbance, inundation). Direct impacts can be either permanent or temporary (see definitions of permanent and temporary impacts immediately below).

*Permanent impacts* are direct impacts that permanently remove or alter a land cover, or that affect a land cover for more than one year during covered activity implementation and/or more than one year after completion of the covered activity (e.g., creating a new road through grassland). Permanent impacts also include indirect impacts to wetlands that result in a permanent (i.e., more than one year after completion of the covered activity) change to wetland functions (e.g., development around a wetland that reduces the surface water supply to a wetland that subsequently results in a reduction in the size of the wetland). Impacts that result in reduction of long-term viability of a plant occurrence are also considered permanent.

*Temporary impacts* are direct impacts that alter land cover for less than one year and that allow the disturbed area to recover to pre-project or ecologically improved<sup>1</sup> conditions within one year (e.g., prescribed burning, construction staging areas) of completing construction. For the purposes of this Plan, all impacts associated with covered activities that have a duration exceeding one year or that take more than one year to restore immediately following construction will be considered permanent.

*Indirect impacts* are defined by USFWS as “those that are caused by the proposed action and are later in time, but are still reasonably certain to occur” (50 CFR 402.02). Indirect impacts in the context of this Plan also include those impacts that occur at the time of the proposed action but beyond the footprint of a project or activity (i.e., beyond the area of land cover disturbance). While more difficult to detect and track, indirect impacts can undermine species viability or habitat quality, especially if multiple indirect or direct impacts work cumulatively to impair the species or to degrade the habitat. Indirect effects that would result from activities permitted by this Plan are listed in **Table 4-1**. This table summarizes the major categories of indirect impacts that could affect each covered species.

*Cumulative impacts* result from the proposed actions’ incremental impact when viewed together with past, present, and reasonably foreseeable future actions. Cumulative impacts are defined under both the ESA and NEPA. HCPs do not require a discussion of cumulative effects as analyzed under NEPA. However, as stated in the HCP handbook, “the applicant should help ensure that those considerations required of the Services by Section 7 have been addressed in the HCP” (U.S. Fish and Wildlife Service and National Marine Fisheries Service 1996:3–15). Accordingly, the Plan addresses the cumulative effects of public or private activities that could result from individually minor but collectively

<sup>1</sup> *Ecologically improved* means that the site functions ecologically better than the functions present on the site prior to ground disturbance.

significant actions that take place over time. Cumulative effects of all projects with a federal nexus will be analyzed under NEPA and will not be addressed in the Plan in accordance with the ESA regulatory guidelines.

The following section discusses specific impact mechanisms for each of the major categories of covered activities.

## 4.3 Impact Mechanisms

In the following discussion, impact mechanisms are grouped for the purposes of analysis and in accordance with the description of covered activities presented in Chapter 2. Unlike Chapter 2, which provides details on the activities themselves, this section provides a description of how these groups of covered activities affect land cover and habitat for covered species. These descriptions provide an overview of the direct and indirect effects that are likely to result from the categories of covered activities. Impact estimates by acres of land cover affected or miles of stream are discussed in Section 4.5 *Effects on Natural Communities/Land Cover* and Section 4.6 *Effects on Covered Species*. Conditions on covered activities that will reduce the impacts described below are presented in Chapter 6 *Conditions on Covered Activities and Application Process*. Avoidance and minimization measures in this Plan (Chapter 6) are designed to minimize injury or death of all covered species during construction and to avoid injury or death of San Joaquin kit fox, western burrowing owl, tricolored blackbird, and least Bell's vireo.

### 4.3.1 Urban Development

Urban development is one of the primary impact mechanisms considered in this Plan, accounting for approximately 60% of all impacts assessed in this Plan. The major impact of new urban development is conversion from undeveloped to developed land cover types. In addition to the net loss of undeveloped land cover in the permit area, such conversion may further isolate remaining natural habitat within the planning limit of urban growth, rendering it less suitable or unsuitable for covered species. Riparian and in-stream impacts may also occur as a result of urban development; however, these impacts are described and assessed under the categories of In-Stream Capital Projects and In-Stream Operations and Maintenance Activities.

Urban development is assumed to result in permanent direct impacts because it is assumed that complete conversion of natural land cover types would occur at project sites in urban areas. Accordingly, no temporary direct impacts on land cover are expected to result from this impact type within the planning limits of urban growth.

Urban development will have indirect effects on biological resources in protected open space within and outside the planning limits of urban growth, including the Reserve System. One significant indirect impact is nitrogen deposition on the

local serpentine grassland community resulting from increased traffic associated with new development. The predicted increase in local and regional vehicular traffic may also result in increased disturbance of covered species in the permit area and loss of covered species from vehicular collisions. An assessment of the impact of nitrogen deposition on natural communities and covered species is presented in Section 4.5.2 *Indirect Effects*.

By increasing the extent of impermeable surfaces, urban development contributes to increased runoff, especially during storm events. Such increases can result in greater levels of scour and/or incision of local creeks, increased sediment loads, alterations of downstream hydrology, and decreased groundwater recharge. Also, addition of new development may increase the amount of pollutants such as grease, oil, and lawn pesticides that can be transported from residences during wet weather. An increase in the quantity of pollutants reaching local creeks through higher runoff may affect the biological and physical characteristics of aquatic habitats. Pollutants can also enter groundwater when development occurs over percolation zones in streams, such as in Coyote Valley. This can affect drinking water quality. In addition, if shallow, “perched” water tables occur, this groundwater can be discharged to surface water as part of summer stream flow (such as in the lower Guadalupe River or lower Uvas Creek). However, design guidelines (see Chapter 6) require construction in urban and rural areas to manage runoff so that existing runoff conditions (i.e., rate of runoff) are maintained and to reduce pollutants entering local streams. High runoff temperature may also result in an increase of in-stream water temperatures when runoff enters local streams. Increased impermeable surfaces may also inhibit natural percolation of stormwater into groundwater basins which may lead to a drawdown in ground water levels. Changes from reduced percolation of runoff are expected to be relatively minor as SCVWD operates several groundwater recharge basins and also extracts water to support local water supplies.

Indirect beneficial impacts to local streams may occur as recycled water is increasingly utilized for urban uses (e.g., landscaping) in place of surface and groundwater. This may result in temporary reductions of in-stream withdrawals, although by the end of the permit term it is likely that all water resources (local, imported, and recycled) will be fully utilized. Increased discharges from water treatment plants may also help to supplement in-stream flows from reservoir releases to support aquatic covered species.

Several other indirect impacts may be expected as urban development increases the human population of the permit area. General use of the study area, including units of the Reserve System where certain types of recreation are allowed, will increase. Increased human use within the permit area may have adverse effects on biological resources in the form of collection and harassment of native species, introduction or spread of diseases, competition from or predation by nonnative species, trash dumping, higher noise levels, increased light pollution at night, spills of hazardous materials, water quality degradation from road runoff, and increased frequency of wildfire ignitions (**Table 4-1**). Incidental take associated with legal recreational uses is only extended to the Local Partners for the indirect effects of allowable recreational uses (take caused by actions of

individual recreationalists is not covered). The level of incidental take of recreational use is assumed to be too minimal to measure and thus is not accounted for in the impact assumptions described below in Section 4.4 *Impact Assessment Methods*. Recreational impacts are greatly minimized by Condition 9, described in Chapter 6, *Conditions on Covered Activities and Application Process*. Impacts are mitigated through the conservation strategy as a complete package that includes conservation associated with contributions to recovery of covered species.

Human population growth can exacerbate the introduction or spread of nonnative species. Nonnative aquatic wildlife is known to have serious impacts on native amphibian populations. For example, aquarium species released in the wild may introduce new diseases to wild amphibian or fish populations. Feral cats pose a serious threat to native birds, especially those that nest on or near the ground, as well as to native reptiles. They can also cause a shift in small mammal populations from native to nonnative species. Ornamental plants and native cultivars<sup>2</sup> may spread to adjacent protected areas and outcompete and displace native species; they can also hybridize (interbreed) with local native plants and thereby disrupt the genetics of the native population. Such hybridization can cause a number of problems for the native plant population, including poor growth and reproduction.

The final locations of Plan reserves are not known, but some reserves are expected to be near or adjacent to urban areas. The Plan conservation strategy includes measures to minimize some of the foregoing indirect effects through actions such as development of design guidelines that reduce impacts from development on natural lands. Additionally, outreach programs for the public, especially landowners, renters, and developers, will educate the local populace on these threats and on ways that they can help minimize them. Despite these measures, it is assumed that indirect effects will occur. Most of the indirect impacts of urban development will occur along or near the boundary between new urban development and new reserves. Because the urban areas are relatively consolidated, this boundary zone will be a comparatively small portion of the total Reserve System. **Table 4-1** lists the major categories of these indirect impacts; these impacts may be particularly pronounced at the urban-wildland interface.

## 4.3.2 In-Stream Capital Projects

Several types of projects will have impacts on in-stream resources. These are discussed below. While some trail construction will occur across streams or in riparian areas, the majority of trails will be designed to avoid these sensitive areas. Accordingly, impact mechanisms for trail construction are discussed in Section 4.3.4 *Rural Capital Projects*.

---

<sup>2</sup> Native cultivars are plants cultivated from native species and bred for specific characteristics; they have lost the original genetic diversity of the species or population from which they were derived.

## Flood Protection Capital Projects

Final designs of flood protection projects described in Chapter 2 are not known at this time. However, conceptual designs have been developed for several projects including Berryessa, mid-Coyote, and upper Penitencia. In addition, SCVWD has completed flood protection projects on the lower Guadalupe River (Santa Clara Valley Water District 2002), the Guadalupe River in downtown San José (Santa Clara Valley Water District 2001), and the upper Guadalupe River (Santa Clara Valley Water District 1999a, 1999b). Conceptual project elements, as well as completed project designs, were used to inform the impact mechanisms described below.

In accordance with SCVWD's Clean, Safe Creeks and Flood Protection Plan, the projects identified for coverage under this Plan include design elements to preserve sensitive natural communities using a mix of setback levees and floodwalls, minimize the use of concrete, protect riparian and wetland environments with revegetation mitigation projects, protect water quality and limit turbidity using sediment control structures, and provide recreational access.

Flood protection projects in the study area are implemented by SCVWD. SCVWD seeks to balance flood control requirements with the habitat needs of riverine and riparian species. This goal is reflected and supported by the Clean, Safe Creeks and Flood Protection Plan, described in Chapter 2, which is focused on four outcomes for projects in local streams: providing flood protection, protecting water quality, enhancing and restoring in-stream and riparian ecosystems, and providing recreational access. Whenever possible (e.g., undeveloped land is available along the outside of the existing levee) and economically feasible (i.e., funding for implementing a large levee reconstruction can be secured), environmentally sensitive design treatments such as levee setbacks and naturalized structural improvements are used instead of channelizing streams in concrete. An example of such an approach is proposed for Berryessa Creek, where banks of the existing channel will be set back and an in-channel floodplain developed to allow the creek more "elbow room" to allow meandering and natural stream hydraulics. Such methods help offset impacts from increased runoff (described above) by reducing flow velocity and increasing roughness, especially during storm events.

However, flood protection projects will sometimes result in some permanent impacts associated with the use of hardscape where naturalized alternatives are not feasible, as well as some temporary impacts associated with construction. The type and severity of both permanent and temporary impacts will vary considerably depending on the scope of specific projects.

Permanent and temporary impacts, both direct and indirect, are expected to occur during implementation of flood protection projects. Riverine and riparian habitat may be permanently affected both during and after construction. Review of the upper and downtown Guadalupe River EIRs reveals a 27% and 50% total impact (i.e., both permanent and temporary), respectively, on riparian and in-stream habitat during project construction (Santa Clara Valley Water District 1999a, 1999b, 2001). Based on these past impact evaluations, and input from SCVWD

engineers regarding current conceptual plans for future projects, some permanent loss of land cover is expected during implementation of covered activities. These permanent losses to land cover types excluding streams are anticipated to average 20% of the total project footprint. Temporary impacts to land cover are anticipated to be approximately an additional 20% of the total project footprint. Permanent impacts will be assessed for loss of natural land cover types that are impacted longer than the time allowed for temporary impacts (defined in Section 4.2 *Definitions*). However, site design for flood protection projects often includes elements to replace and/or improve habitat on site as part of SCVWD's goal of balancing flood protection and habitat value. SCVWD may receive restoration credit for such actions as described in Chapter 9, Section 9.4.1 *Habitat Plan Fees* subheading *Aquatic Restoration or Creation Provided in Lieu of Wetland Fee*. Permanent land cover loss may be attributed to installation of hardscape on the channel bed and banks; installation of levee walls, access roads, and outlet and inlet structures; off-channel detention basins; maintenance road construction; and increased recreational use. Impacts associated with off-channel detention basins fall outside of in-stream areas but within the planning limit of urban growth and as such, impacts are assumed as part of the urban development analysis. Access roads associated with flood protection projects may also be designed for use as recreational trails. Because permanent, direct impacts to land cover associated with such trails are already accounted for through the design of access roads, no additional permanent impacts are anticipated. However, it is possible that indirect and temporary impacts may occur through recreational use (e.g., increased harassment resulting from recreationists or dogs). In addition, changes in sediment transport and deposition within the channel due to channel realignment and changes in channel substrates may occur. Loss of in-stream complexity due to installation of hardscape or channel straightening could lead to increased scour along earthen channels.

Direct, temporary impacts of flood protection projects are most likely to occur during construction when use of heavy equipment may entail loss of vegetation for access, and increased turbidity, in-stream temperature, dust, and noise. Most, if not all, flood protection projects are likely to require dewatering of portions of the channel during construction. These activities will result in temporary reduction in habitat quality and/or loss of habitat, including potential impacts to covered avian species using riparian habitat for nesting. However, most temporary construction impacts can be avoided or minimized through the appropriate use of avoidance and minimization measures (see Chapter 6). Temporary impacts are also likely to occur at staging areas used during construction. Existing developed areas such as access roads or adjacent parking lots will be targeted for use as staging areas. If such areas are not available, highly disturbed ruderal areas will be selected. Staging will not be established in sensitive areas such as stream beds, riparian, or serpentine areas.

Indirect impacts on groundwater may occur if the channel bed is altered to prevent infiltration of flows (e.g., through installation of concrete). The construction of new levees could also prevent streams from naturally meandering, which could lead to channel incision and erosion. Continued use of groundwater recharge ponds and construction of new ponds as described in Chapter 2 may help offset any changes to groundwater levels that could occur

due to installation of flood protection projects. Installation of flood protection projects is not expected to result in significant changes to in-stream flow or velocity. The effects of straightening channels are better understood today than in the past, and new flood control structures will be designed to mimic natural flow conditions as closely as possible. Where hardened elements are required, appropriate flow dissipation devices will be incorporated into the design to prevent flows from increasing to the point that fish cannot move upstream or are washed downstream. In addition, as described above, flow bypass channels may be installed to reduce excessively high flows during storm events that cause erosion in earthen channels.

## **Levee Reconstruction**

Direct, permanent impacts will occur when levees are reconstructed and then maintained in accordance with FEMA and Corps guidelines. Since the events of hurricane Katrina, FEMA and the Corps have tightened rules on how levees must be maintained for flood protection purposes. SCVWD currently conducts vegetation management on these levees under the Stream Maintenance Program and vegetation management follows the Corps guidelines.

It is expected that once reconstructed, levees will be maintained under the Stream Maintenance Program free of all vegetation with the exception of grasses and non-woody shrubs. Therefore, all non-ruderal vegetation is assumed to be permanently lost once reconstruction is complete. SCVWD will avoid areas that were developed for mitigation of previous projects. Most levees will be reconstructed in the same footprint as existing levees. However, where space allows (i.e., where development does not encroach up to the outer edge of the levee), there may be opportunities to set back the levees and create a wider floodplain area that is permitted to support trees and other riparian vegetation.

Direct, temporary impacts may occur during levee construction similar to those associated with flood protection project construction. Similarly, the proper use of avoidance and minimization measures can greatly avoid and minimize construction-related temporary impacts.

Indirect impacts associated with levee reconstruction may include a reduction of in-channel cover and/or woody debris that occurs over time due to a reduction in streamside riparian vegetation. Reconstruction of levees is not expected to result in changes to in-stream flow or velocity because levees will be reconstructed similar to their original designs.

## **Canal Reconstruction, Realignment, and Decommissioning**

SCVWD anticipates needing to fully reconstruct or decommission all of its water conveyance canals over the course of the permit term. Canals may be reconstructed in place, replaced with a pipeline installed within the alignment of

the existing canal footprint, replaced within different alignment that is also within a public right-of-way, or decommissioned. Reconstruction or replacement with a pipeline will require ground disturbance and complete vegetation removal within the entire footprint of the canal. Reconstructed canals may allow some vegetation to reestablish in or along the canal; however, for the purpose of the impact analysis, complete loss of vegetation is assumed. Canals will not be flowing at the time of construction, thus there would be limited impacts to streams that are connected to the canals are expected as a result of reconstruction. Small, discontinuous wetlands may occur in canals that are fed by perennial seeps and springs. These wetlands and some covered species may be affected by canal reconstruction or installation of a pipeline and these affects will be considered impacts where they occur. Canal decommissioning may also have construction-related adverse effects when hardscape and other infrastructure are removed. However, removal of such infrastructure will also allow existing canals to return to a more natural state; thus resulting in long-term beneficial effects.

Direct impacts associated with canal reconstruction or installation of a pipeline would be similar to those direct impacts described for other construction projects including temporary increases in noise and dust. Implementation of avoidance and minimization measures described in Chapter 6 would reduce the potential for these types of indirect temporary impacts.

Decommissioning of a canal entails removal of unnecessary concrete and other materials from the site and allowing the canal to return to a more natural state. It is likely that decommissioning would enhance canals for natural resource management purposes, but credits for such enhancement are not assumed in the impact analysis. Minor indirect temporary impacts maybe associated with concrete removal activities. Canals will be dry at the time of removal activities, thus no impacts to streams that are connected to the canals are expected as a result of decommissioning.

## Three Creeks HCP In-Stream Capital Projects

The primary capital project associated with the proposed Three Creeks HCP is retrofit of five of SCVWD's six dams in the north portion of the permit area. These projects include the development of borrow sites to support dam retrofits as well as associated infrastructure to provide supplemental flows during a dewatering event. As such, the impact mechanisms associated with dam repair and seismic retrofit are described independently of the proposed Three Creeks HCP in the following section *Dam Seismic Safety Retrofit*. A supplemental water supply is proposed as part of the Three Creeks HCP Conservation Program. Impact mechanisms associated with this activity are discussed in Section 4.3.3 *In-Stream Operations and Maintenance*.

## Three Creeks HCP Conservation Program

The proposed Three Creeks HCP includes a suite of activities to enhance conditions for steelhead trout and Chinook salmon, while maintaining use of local watersheds to meet the water supply needs of northern Santa Clara County. The Three Creeks HCP Conservation Program includes nine main components that will receive take coverage under this Plan.

- Geomorphic Rehabilitation
- Almaden Reservoir Fish Passage
- Gravel Enhancement Program
- In-Stream Habitat Enhancement
- Fish Passage Enhancement
- Reservoir and Recharge Re-Operation
- Upper Penitencia Creek Management Program
- Supplemental Flow Program
- Monitoring Program

Geomorphic rehabilitation, Almaden Reservoir fish passage, gravel enhancement, in-stream enhancement, and the fish passage enhancement program are discussed below. Reservoir and recharge re-operation, Upper Penitencia Creek management, supplemental flows, and monitoring are described in Section 4.3.3 *In-Stream Operations and Maintenance* subheading *Three Creeks HCP Conservation Program*.

### Geomorphic Rehabilitation

The criteria for geomorphic rehabilitation ensure that affected reaches of the channels below the reservoirs will be substantially modified and improved in terms of factors such as channel sinuosity and riffle-pool habitat. Implementation of the proposed rehabilitations requires substantial construction. New channel will be graded, large woody debris will be added, and the channel will be replanted. During this process, the existing channel and most of the riparian habitat along the channel will be disturbed. During construction, flow will be bypassed around the construction site and there may be short term loss of stream habitat, including increased temperature in the water that is bypassed around the project site.

Geomorphic rehabilitation will sometimes occur within the current active channel and will have the beneficial effects of permanently separating pond habitats from riverine habitats and replacing existing slow-moving ponded areas with stream riffle-run-pool-run complexes.

### Almaden Reservoir Fish Passage

SCVWD proposes to provide steelhead with passage to upstream habitat that is currently blocked by Almaden Dam as part of the proposed Three Creeks Conservation Program. SCVWD has not yet identified a preferred alternative to

providing passage over Almaden Dam; however, SCVWD is currently considering a range of alternatives from trap and truck to construction of a fish ladder.

One of the goals of this program is to isolate juvenile salmonids emigrating downstream from the reservoir to reduce the potential for predation by exotic, predatory species living in the reservoir. As such, a juvenile collection facility may be constructed just upstream of the reservoir. Construction of this facility will require both on- and off-channel disturbance. Off channel disturbance will result in ground disturbance and permanent loss of some land cover types, as well as potential indirect impacts similar to those described in this chapter for other development projects. On-channel activities may result in a small amount of permanent stream loss where a diversion dam and fish screen are placed. Construction of the diversion dam will occur during the summer when natural inflows are at their lowest. Any remaining flows will be diverted around the project site as required by avoidance and minimization measures described in Chapter 6.

A trap and truck operation will have the least effect on covered species. This approach will utilize existing roads for moving fish from downstream of the dam to the upstream end of the reservoir. To trap adults, a collection facility at the base of Almaden Dam would be required. This activity could require a portable collection system placed in the channel. Access to the channel and staging for placement of the system may result in some permanent impacts to the stream bank and any riparian vegetation present. Access will be sited to avoid sensitive habitat to the extent feasible. This approach does not result in any changes to flows.

Construction of a fish ladder is likely to have the greatest effect on non-developed land cover types, including streams. Because the design of the project is not known, it is assumed that the ladder would not be designed as part of the existing dam infrastructure and would instead be constructed largely on non-developed land cover types. Depending on the level of separation of juvenile steelhead from the reservoir pool, a facility may be required to bypass fish around the dam and around the reservoir. If implemented, this facility would likely be constructed around the perimeter of the reservoir in non-developed land cover types. Ground disturbance impacts would be similar to other construction projects. Temporary construction impacts such as noise and dust may be more significant depending on how much excavation is required to construct the ladder and new access road. Operation of the fish ladder will require some amount of water to be released from the reservoir and possibly provided by supplemental sources to provide flows sufficient to encourage migration of adults and simply to fill the fish ladder, thus allowing fish passage. This may result in a small increase in downstream flows when the ladder is operational.

For the purposes of the impact analysis, it is assumed that up to 30 acres of non-developed land cover types may be permanently impacted, as well as up to 50 feet of stream lost where collection facilities at the base of the fish ladder are placed in the stream. Up to 5 acres of temporary construction impacts may also

occur on non-developed land cover types, and up to 30 feet of temporary stream impacts.

### **Gravel Enhancement Program**

Gravel traps will be constructed below the high-waterline of the reservoir. Because reservoirs provide little or no habitat for the covered species, this is not considered an impact. Some minor permanent effects to surrounding terrestrial land cover may result from the construction of new access roads between the perimeter road of the reservoir and the reservoir itself. Temporary impacts associated with gravel extraction will be minimized because excavation will occur in the summer when the stream is dry and the reservoir level has dropped below the location of the gravel trap (i.e., the gravel trap will be dry). Existing access roads will be utilized to transport gravel excavated from these traps. Placement of excavated and processed gravel in downstream reaches could increase turbidity. To minimize the severity and extent of increased turbidity, gravel will be cleaned prior to being deposited downstream of reservoirs. Gravel placement will avoid the California red-legged frog and foothill yellow-legged frog breeding seasons, if possible.

If the new gravel augmentation service yard is constructed on an already developed site, no new permanent impacts are anticipated. If the new service yard is constructed on disturbed lands (i.e., urban development land cover types that provide some habitat value to Plan species), construction will result in a conversion of these land cover types to a fully developed land cover type (e.g., urban-suburban or developed agriculture). Temporary construction impacts will be similar to those described above for development regardless of the land cover type on which the project is constructed.

### **In-stream Habitat Enhancement**

Cover enhancement includes localized installation of in-stream cover elements such as boulders, large woody debris, or biotechnical treatments along stream banks. These activities may create temporary disturbance to stream bank, bed, and adjacent riparian habitat. Short reaches of channel may require dewatering that includes bypassed flow around the construction site. If exotic vegetation removal is conducted, there may be a temporary loss of some canopy or stream-side understory vegetation function until newly planted vegetation matures. Temporary impacts are expected to be similar in scale to the temporary impacts incurred with maintenance of the water supply facilities in channels below reservoirs, but are not expected to recur at a given site (i.e., once a site is enhanced, it will not likely be targeted for enhancement again in the future).

### **Fish Passage Enhancement**

In-stream impediments to fish passage may be modified or removed to improve habitat connectivity. Impacts may occur as the result of construction activities required to improve passage (e.g., removal of a culvert or reconfiguration of an in-channel weir). If sites support flow during construction, avoidance and minimization measures described in Chapter 6 will be implemented to protect water quality downstream of the site. Depending on the projects, some ongoing

maintenance similar to that of the water supply facilities in the channels below the reservoirs may be required.

## Dam Seismic Safety Retrofit

Four of the major dams operated by SCVWD in the study area (**Figure 2-6**), two County Park dams, and one City of San José dam may need to be retrofitted in accordance with DSOD and FERC regulations for dam safety and design change. Several direct impacts would result from dam reconstruction, many of which are similar to the direct impacts described above for other in-stream capital improvement projects.

Direct temporary impacts related to dam reconstruction are anticipated to be minimal due to implementation of avoidance and minimization measures and mitigation measures. However, some temporary impacts are expected during staging of construction equipment and with the installation of a flow bypass during construction. In addition, there is also the potential for direct impacts (including noise, dust, and light [if construction activity continues at night]) on tricolored blackbirds, burrowing owls, California red-legged frogs, foothill yellow-legged frogs, California tiger salamanders, and western pond turtles. Implementation of Condition 15 *Western Burrowing Owl* and Condition 17 *Tricolored Blackbird* would help alleviate some of these impacts.

Dam reconstruction projects will be conducted to respond to existing and future safety requirements as required by DSOD and FERC, not to a need to increase reservoir capacity for expanded water supply.

## SCVWD Dams

### Borrow Sites

As described in Chapter 2, potential borrow sites<sup>3</sup> for dam reconstruction includes the following options.

- The upstream delta of the reservoir.
- The reservoir basin.
- Existing quarries.
- New quarries (a) in the reservoir basin, (b) in the canyon below the dam, or (c) in the alluvial plains within the Habitat Plan permit area.

Alluvial borrow extraction will be focused on areas where alluvial materials may be obtained without impacting wetlands, stream channels, existing or proposed Habitat Plan reserves, and the habitats of Bay checkerspot butterfly, California

<sup>3</sup> These are potential borrow sites located within the permit area of the Habitat Plan. Take associated with borrow sites located in the portion of the Three Creeks HCP permit area that does not overlap with the permit area of the Habitat Plan are possible but are not covered activities under the Habitat Plan and would require authorization through the Three Creeks HCP or another regulatory mechanism.

tiger salamander, or California red-legged frog. This has placed emphasis on obtaining borrow from agricultural and other disturbed or barren habitats, from existing quarries, and from the reservoir area below the maximum reservoir pool elevation. Rockfill excavation at Anderson Dam is assumed to be within the reservoir pool areas below the high water line and would be extracted once the reservoir is dewatered for the retrofit.

In all cases, the analysis has assumed that earthfill borrow sites will be excavated to a maximum depth of 40 feet, resulting in permanent loss of all habitat. Borrow sites may be converted to recharge areas or may fill naturally if groundwater levels are high. Alluvial areas affected would primarily be agricultural (Anderson, Calero, and Almaden) but some natural habitats will be affected. Species effects for alluvial sites tend to be low, reflecting the disturbed nature of the habitats below the dams. The functional value of agricultural lands most likely to be used for alluvial borrow at Anderson, Calero, and Almaden dams is primarily movement and foraging. Species impacts associated with the other types of land cover are likely to be greater, and the potential for impacts to covered plants increases proportionally.

Direct impacts include permanent loss of land cover, potential loss of individuals of covered species during construction and material hauling, and fragmentation of habitat at the landscape level. Noise, dust, and light related effects, previously described for nighttime retrofit activities, are likely to occur as a result of night time borrow extraction. Implementation of avoidance and minimization measures described in Chapter 6 are expected to reduce potential indirect impacts.

### Dewatering Events

Dam seismic safety retrofit will likely require reservoir draining, construction in the dry reservoir, and reservoir refilling to the point at which the reservoir is re-operated according to applicable rule curves (collectively referred to as a dewatering event). The impacts associated with each of these actions are described below.

**Table 2-4** shows the maximum covered release flows resulting from reservoir draining during a dewatering event<sup>4</sup>. Due to the unique characteristics at each dam site, a reservoir-specific dewatering plan will be developed and submitted to the Wildlife Agencies for review and approval prior to the first dewatering event for each reservoir (see Chapter 8, Section 8.7.3, subheading *Additional Review* for details of this process). This dewatering plan will specify the timing, frequency, and duration of reservoir releases associated with dewatering events. Since the level of detail is not known at this time, the maximum covered reservoir release flows shown in **Table 2-4** are provided as anticipated worst-case scenario for impact evaluation based on the professional judgment of the SCVWD. If at the time a dewatering plan is developed SCVWD determines the flow releases will be higher than those in **Table 2-4**, additional consultation with

<sup>4</sup> Pulse flows implemented for the benefit of anadromous fish species (see Section 2.3.4) may be greater than the flows anticipated for draining of a reservoir as part of a dewatering event. These higher flows are also covered by this Plan.

the Wildlife Agencies will required and additional mitigation may also be required.

Although up to 18 dewatering events are covered under this Plan, SCVWD will only undertake a dewatering event if absolutely required to maintain dam safety. In addition, the dewatering plan will identify avoidance and minimization measures that will reduce the potential effects of draining a reservoir. A key avoidance and minimization measure that SCVWD anticipates including in most, if not all, dewatering plans is a ramping schedule for flows. Ramping flow releases (i.e., slowly building up to a maximum release flow over a specified amount of time) when beginning reservoir draining will help avoid washing covered species downstream. Ramping down flows at the end of draining will help avoid drying back the channel faster than covered amphibian and reptile species can move to new locations to avoid stranding.

After accounting for avoidance and minimization of draining impacts, draining the reservoir may have residual adverse impacts to covered species. Reservoir dewatering will initially result in higher reservoir releases affecting the stream downstream of the reservoir. Extended periods of high flow will affect a significant portion of the channel downstream from the affected reservoir. Increases in flow may affect California red-legged frog egg masses or juveniles if flows are released in early spring before these species have had the opportunity to move out of streams. Foothill yellow-legged frogs may also be affected by high flows; however, this species is more likely to be found in the upper watershed (above dams). Consistent high flows, if started early enough in the year and continued through late spring, may facilitate breeding by providing a reliable water source and may also reduce the potential for stranding. High flows are not expected to affect western pond turtle breeding as this species tends to lay its eggs in uplands away from the active channel.

The Implementing Entity will monitor the effects of flow regulation (including dewatering events) on California red-legged frog, western pond turtle, and foothill yellow-legged frog populations that occur in streams hydrologically affected by existing dams in the permit area (Chapter 7, Section 7.3.3 *Species-Level Actions*). This monitoring data will inform the adaptive management process and help to minimize effects on these downstream populations. Results will be reported to the Wildlife Agencies within 60 days of the conclusion of each dry season and wet season dewatering event. Based on these results, the Wildlife Agencies may require an adjustment in the maximum reservoir release flows in **Table 2-4**. During reservoir drawdown, exotic fish and other aquatic species contained in the reservoir may enter the downstream channel in large numbers, resulting in increased predation on aquatic covered species. While these exotic species already exist below the dams, increased numbers of exotic species may increase the level of predation. Potential impacts associated with exotic species will be reduced with implementation of avoidance and minimization measures for dewatering described in Chapter 6 that may be incorporated into the dewatering plan.

Once the reservoir is drained, releases from the reservoir will be limited to bypassed inflow collected at an upstream location and flow from groundwater

seepage. Bypassed flows would be released into the stream immediately below the footprint of the project; therefore, no complete drying out of the channel immediately below the project footprint is expected. There may be some local runoff from tributary watersheds and from domestic irrigation, and in some locations the channel may be fed by upwelling of groundwater, but in all but the wettest years, perennial flow is not common. It is expected that, without supplemental water sources, much of the channel below the dewatered reservoir will go dry and remaining wetted portions would be of poor habitat quality. A supplemental flow system may be installed as part of the proposed Three Creeks HCP Conservation Program at Anderson and Calero Main dams. For reservoirs where supplemental flows are not provided, this impact could potentially affect the area in the channel from the base of the dam to the first confluence with another stream that is fed by a different reservoir. Watershed level impacts will be avoided through measures described in Chapter 6 that only allow one reservoir per watershed to be dewatered at one time.

Loss of water in channels downstream of dams is likely to affect amphibians and reptiles covered by this Plan, and may also affect riparian vegetation along creeks below dams. For the past 10–15 years, dry-back of channels below reservoirs has been minimized to avoid species impacts. Some seasonal dry-back has occurred on Uvas and Llagas creeks, but has been almost entirely avoided on Coyote Creek and Guadalupe River with the exception of approximately 600 feet on Guadalupe Creek in the summer of 2007 due to drought conditions. Thus, covered amphibians and reptiles are not accustomed to seasonal fluctuations in flows, particularly in the northern watersheds of the study area. Some stream segments in the study area below reservoirs currently dry out on an annual basis and reduced flows during a dewatering event may be similar to natural drought conditions. During such times, it is likely that adults of these species will move away from dry streams in search of water in nearby areas. Because dewatering events are generally only expected to last one season, riparian vegetation is not likely to be substantially altered during dewatering. Impacts may be more severe during an extended dewatering event (up to 3.5 years for seismic safety retrofit at Anderson Dam and 2.5 years for all other dams) if occurring during a drought. Immediately below dams, vegetation will still benefit from the natural drainage of the watershed which will be bypassed around the dam. Further downstream, runoff from urban areas is often considerable and enough to keep flow in the channel throughout the year.

Maintaining the reservoir free of water during construction will eliminate the majority of aquatic habitat upstream of the dams around the reservoir perimeter for aquatic covered species, including western pond turtles. Covered species using this area would be required to seek other habitats, which will be limited and which will affect their ability to re-establish following dewatering and repair of the reservoir facilities. Under the worst-case scenario, inflow may be non-existent for several months of the construction period, probably the months of July, August, and September when evapotranspiration is highest and ambient air and water temperatures are also high.

Construction activities occurring in the reservoir during dewatering will implement avoidance and minimization measures as described in Chapter 6, Condition 4 *Stream Avoidance and Minimization for In-Stream Projects*.

During refilling of the reservoir, outflow may also be constrained. First, the reservoir will not make releases until the reservoir has reached the level of the lowest outlet gate. Second, early in the refilling, water quality requirements may limit releases to maintain suitable quality of bypassed flows. Third, SCVWD will endeavor to re-fill the reservoir for both water supply and sustained-flow considerations. Winter flows may be constrained, affecting the length of transition time back to sufficient storage for intended operability. In a dry period, a drained reservoir may not be re-operated according to applicable rule curves until up to 2.5 years from the time reservoir draining is initiated. A dewatering event that takes longer than 2.5 years, with the exception that Anderson Reservoir is covered up to 3.5 years for a dewatering event associated with a seismic safety retrofit, is not a covered activity and SCVWD would initiate consultation with the Wildlife Agencies.

Covered species are unlikely to move into dewatered reservoirs as these sites will, in general, be continuously disturbed until refilling starts. If a project-specific situation arises where impacts to covered species could occur, the potential impact would be identified in the dewatering plan and species surveys as described in Chapter 6 would be required.

## County Parks Dams

As discussed in Chapter 2, County Parks dams are much smaller than SCVWD dams, thus, while many of the construction impacts will be the same as those described for SCVWD dams, the scale is much smaller.

Sandywool Lake is located along a small tributary (less than 0.75 miles) to Arroyo de los Coches. Engineered channels allow natural flow from above Sandywool Lake to bypass the lake and continue in the tributary to its confluence with Arroyo de los Coches. Sandywool Lake is used for irrigation and is not managed for water supply to the tributary, thus, the channel below the lake is typically only supplied with natural flows. Dewatering the lake is not expected to affect this tributary or local riparian vegetation.

Grant Lake is not located on a stream, but it does have a drainage connection to Arroyo Aguaque Creek, a tributary to Upper Penitencia Creek. Dewatering Grant Lake is not expected to affect the water supply for local streams.

Borrow sites will be sited in the California annual grassland land cover type or in other already disturbed areas. Whenever possible, borrow sites will be used to create habitat for covered species (e.g., a pond for California tiger salamander). In these cases, development of borrow sites will result in the conversion of one land cover type (e.g., grassland) to another land cover type (e.g., pond). Areas around the borrow site may be temporarily disturbed during borrow site

construction. Location of borrow sites will be within County parks, but exact locations are unknown at this time.

## **City of San José Dams**

As discussed in Chapter 2, Cherry Flat Dam is much smaller than SCVWD dams, thus, while many of the construction impacts will be the same as those described for SCVWD dams, the scale is much smaller.

Cherry Flat Reservoir is located on Upper Penitencia Creek, almost at the top of the catchment; the watershed above the reservoir is 2.4 acres. This reservoir is not currently managed to support fish flows in Penitencia Creek, although it is managed to maintain minimal flows through Alum Rock Park (approximately 0.5 cubic feet per second [cfs]) during summer months. SCVWD has a release point from a pipeline that provides most of the flow in this channel based on SCVWD operational needs, including flows to support fish. Dewatering the lake may reduce the 0.5 cfs summer flows.

The borrow site for this project will avoid sites in areas designated as high or medium priority for conservation in this Plan. Areas around the borrow site may be temporarily disturbed during borrow excavation. Borrow sites will be subject to Wildlife Agency review and approval during implementation of the Plan (Section 8.7.3 *Wildlife Agency Responsibilities*).

## **Dam Instrumentation Project**

As described in Chapter 2, the Dam Instrumentation Project includes the installation of piezometers, inclinometers, survey monuments, real-time monitoring systems, seepage collection systems, reservoir level gauges, and seismographs related to the maintenance of dams in the permit area. Implementation of these activities will result in permanent and temporary impacts associated with installation of equipment and subsequent maintenance. All activities associated with the Dam Instrumentation Project will occur within the same areas as will be affected under the Dam Maintenance Program (described below).

## **In-Channel Groundwater Recharge Facilities**

SCVWD plans to re-operate the Ford Road Groundwater Recharge Pond and the Church Avenue Groundwater Recharge Pond. Both ponds were previously constructed but the Ford Road facility has been out of use and the Church Avenue facility has been operated at reduced capacity. The Ford Road reoperation includes expansion of the site to include up to three additional new ponds. This action would result in the conversion of existing land cover types to the pond land cover type, although these new ponds will be managed to support water supply operations and will not likely support use by covered species. As

described in Chapter 2, Ford Road Pond will be supplied by flows from a new pipeline that receives flows from a new diversion upstream of Ford Road Ponds at Metcalf Road. This new diversion will also provide flows to the Coyote Percolation Pond after it is separated from the main channel as part of the proposed Three Creeks HCP Conservation Program. Church Avenue Pond is supplied by an in-channel diversion which may require rehabilitation.

New construction or rehabilitation of in-channel diversions will affect the stream bank and riparian vegetation surrounding the diversion structure. The new structure will permanently impact riparian land cover types while the rehabilitated structure will be temporarily disturb riparian land cover types where the diversion is rehabilitated. The footprint of the diversion is not expected to change in size, thus impacts to riparian vegetation at the diversion are expected to be temporary during construction. Additional permanent impacts resulting from re-operation of the ponds includes conversion of the dried out pond bed (currently characterized by golf course/urban parks and grain/row-crop/hay/pasture land cover types) to pond land cover type.

Re-operation of the Ford Road and Church Avenue groundwater recharge ponds is not expected to affect in-channel flows. Ford Road pond is being re-operated and expanded in anticipation of reduced in-channel recharge that is expected to occur when the currently on-channel Coyote and Ogier percolation ponds are separated from Coyote Creek. Construction and operation of Ford Road ponds will allow SCVWD to maintain the same level of water diversion to the groundwater basin. As described in *In-Stream Operations and Maintenance* subheading *Proposed Operating Rules for Water Supply Facilities in the Uvas and Llagas Watersheds* (National Marine Fisheries Service et al. 2009), Church Avenue ponds will divert flows from Llagas Creek when reservoir capacity allows, consistent with anadromous fish flow and on-channel recharge requirements. If, when these projects are ready to be implemented, SCVWD identifies a potential change in downstream flows due to re-operation that may adversely affect covered species, additional consultation with the Wildlife Agencies will required.

## **New Bridge Construction and Replacement/Rehabilitation**

It is estimated that all existing bridges in the permit area will need to be replaced approximately once within the Plan's permit term. Rebuilding all existing bridges, as well as constructing new bridges, will result in impacts on natural communities and covered species. New and rehabilitated bridges will be designed to federal and state guidelines at the time of construction. Conditions on covered activities described in Chapter 6 encourage the use of free-span bridges; however, wide crossings on major roads will likely require construction of pilings in creek beds. Installation of pilings, piers, and/or footings may contribute to roughness in the stream and slow flows in the vicinity of the pilings. Sediments and vegetation may become trapped on the upstream side of the piling, potentially causing further disruptions to flow. Also, scour may occur

immediately downstream of pilings and contribute to channel erosion and downstream sedimentation. In such cases, conditions described in Chapter 6 will be applied to assess the potential effects of a specific bridge design and to implement design elements that will reduce potential negative effects. Reconstruction projects may entail expansion of the existing footprint up to twice as wide as the existing footprint to account for increased traffic demand or new safety requirements such as pedestrian and bicycle access and wide shoulders for emergency access. Such expansion will result in permanent and temporary impacts on terrestrial and aquatic land cover types.

The amount of habitat loss will depend on whether the project is new construction or rehabilitation of an existing structure. Use of standard construction mitigation measures (e.g., proper management of dewatering activities) and avoidance and minimization measures will help to reduce or prevent temporary impacts on water quality during construction.

The County of Santa Clara Roads and Airports Department anticipates one of its road connection projects will require a new bridge across Llagas Creek. A new bridge across Gavilan Creek will also be required for a VTA road extension project. Approximately 75% of new bridges will be related to private development and will be intended for access use by residents in those areas. New bridges constructed in County parks or for access to parts of the Reserve System will be carefully managed for proper use on newly accessible lands. Construction of new bridges outside the planning limits of urban growth may result in indirect impacts associated with increased access to areas that are currently less accessible, including reserve lands that support natural land cover types and/or covered species. As described above in Section 4.3.1 *Urban Development* increased use of open space that is facilitated by new creek crossings may result in impacts on land cover and covered species related to introduction of nonnative species, general use, and illegal activities such as trash dumping. However, indirect impacts related to bridge reconstruction are anticipated to be minimal. Reconstructed bridges are not anticipated to encourage additional traffic beyond that expected on the basis of existing and planned land use patterns.

## Streamside Trails and Crossings

As discussed in Chapter 2 and above under *Flood Protection Capital Projects*, SCVWD plans to develop stream-side trails along existing maintenance roads and along new maintenance roads installed as part of flood protection projects. In addition, County Parks and the cities also plan to develop new trail projects, some of which will occur in in-stream areas. Direct impacts from establishing trails along existing maintenance or access roads would have minimal, if any, new direct impacts to land cover as the trail would be placed along an existing road. New trails outside of existing roads or trails would have new impacts to vegetation removed for project construction. Impacts may also occur where new signage is installed. However, whenever possible, signage will be installed in disturbed areas.

Indirect impacts related to development of trails are largely related to ongoing use of trails. Expanding access to stream side areas exposes the stream and riparian areas to higher levels of use which may result in increased pollutants in the stream such as trash, trampling of vegetation, and vandalism. Most of the stream side trails developed in the permit area will be along streams maintained by SCVWD for flood control purposes. The majority of these maintained streams are located in urban or suburban valley floor areas. Trails in the Reserve System and outside of urban or suburban areas will be sited outside of the riparian corridor thus reducing the opportunity for these types of indirect impacts to streams (see Chapter 6, Section 6.4.2, subheading *Condition 4 Stream Avoidance and Minimization for In-Stream Projects* and **Table 6-3**).

### 4.3.3 In-Stream Operations and Maintenance

Many operations and maintenance activities in streams may have direct and indirect impacts on natural land cover types and covered species. A discussion of the operations and maintenance activities that may cause impacts is provided below.

#### Facility and Stream Maintenance

Direct impacts of in-stream operations and maintenance activities may result from maintenance of facilities such as bridges, culverts, dams, trails, and roads in the riparian zone. Impacts may also occur during maintenance of streams used for flood control and associated infrastructure such as access roads. Stream maintenance activities may include sediment removal, bank stabilization, levee maintenance, access road maintenance, and vegetation clearing, including fire break maintenance and rodent control, if such action becomes necessary (rodent control measures will be minimized under the Plan).

County Parks and the Cities of Gilroy and Morgan Hill also conduct some in-stream maintenance on their properties. In-stream operations and maintenance activities conducted by cities focus mostly on maintenance of trails and overhanging riparian vegetation. In-stream maintenance activities conducted by County Parks are similar to activities conducted by SCVWD under the Stream Maintenance Program, but with reduced frequency and on a smaller scale. County Parks attempts to replace culverts with in-kind materials and in the same footprint as the existing culvert. However, new and reconstructed culverts are required to be in compliance with conditions in Chapter 6 which may require some design modifications. These Local Partners may also conduct small-scale bank stabilization and sediment removal projects.

Direct impacts associated with in-stream operations and maintenance occur while accessing project sites (e.g., natural land cover is removed to reach a gage or bank stabilization site) or as a result of implementing an operations and maintenance project (e.g., sediment removal). Additionally, maintenance of facilities such as repair and installation of fencing or a monitoring gage may

require vegetation removal in order to access the project site; such vegetation removal would constitute temporary impacts on natural land cover types in the immediate vicinity.

Maintenance of in-stream infrastructure, including trails in riparian areas and bridges, has the potential to result in direct temporary and permanent impacts. However, all project proponents are required to implement the conditions on covered activities described in Chapter 6, including implementation of avoidance and minimization measures.

Direct temporary impacts associated with facility maintenance potentially include increased noise or dust during activities utilizing heavy equipment for mowing or resurfacing roads. Staging areas will be temporarily disturbed by workers and construction equipment. In such cases, application of avoidance and minimization measures would reduce these impacts.

## **Sediment Removal and Mercury Remediation**

As described in Chapter 2, minor mercury remediation projects may be undertaken by Local Partners incidental to sediment removal projects. Sediment removal in stream reaches downstream of abandoned mercury mining operations has the potential to release mercury into the water column and to allow mercury to move downstream of project sites if work is conducted in an active channel. In local streams, mercury may be converted by bacteria into methylmercury, which is highly toxic. Methylmercury may be taken up by insects and other invertebrates which, in turn are consumed by fish and other organisms up the food chain. Over time, methylmercury may bioaccumulate in fish and may cause reduced fertility, impaired growth and development, and abnormal behavior. However, conditions on covered activities require dewatering prior to commencement of work that may contain mercury in the sediment. No indirect effects of sediment disposal are anticipated, because removed sediments are tested for mercury and, if required, are disposed of in a proper receiving facility.

## **Reservoir Operations under DSOD Interim Storage Restrictions**

Reservoir operation under DSOD interim storage restrictions could affect the implementation of the proposed Three Creeks HCP Conservation Program target flows or future operating rules for Uvas and Llagas watersheds, particularly efforts to modify reservoir release schedules to address flow and temperature issues. Over the last 12 years of DSOD storage restrictions, SCVWD has been generally successful in avoiding dry-back of channels. As noted above under *Dewatering Events*, for the past 10–15 years, dry-back of channels has been limited to some seasonal dry-back on Uvas and Llagas creeks, but has been almost entirely avoided on Coyote Creek and Guadalupe River.

However, increased storage restrictions would further reduce reservoir storage. Lower reservoir storage requires that summer flow regimes will be lower than under the proposed Conservation Program and dry back of the affected channels will occur earlier. This may result in stranding of California red-legged frog or foothill yellow-legged for embryos and tadpoles during dry back. During summer, SCVWD does not have water rights to detain natural flows in the reservoir. These flows are by-passed around the reservoir to help maintain a wetted channel, even though it may not reach the requirements of Conservation Program flows. During wet years, by-passed flows are greater and alternative flows from tributaries or groundwater upwelling also help to maintain a wetted channel below dams.

In addition to natural flows (from by-pass or groundwater upwelling), SCVWD anticipates installing supplemental water supply systems at the base of Anderson and Calero Main dams as part of the Conservation Program. Once functional, these systems can be used to meet Conservation Program flow targets (and therefore a wetted channel) during implementation of DSOD interim storage restrictions.

As described above, the Implementing Entity will monitor the effects of flow regulation on California red-legged frog, western pond turtle, and foothill yellow-legged frog populations that occur in streams hydrologically affected by existing dams in the permit area and report to the Wildlife Agencies.

SCVWD expects that it will be able to meet most conservation flows described for the proposed Three Creeks HCP Conservation Program under DSOD restrictions at all times, with perhaps the exception of during a drought. Stream reaches that are dry for more than one year as a result of DSOD storage restrictions will be considered permanently impacted for the purposes of this Plan. Because SCVWD does not anticipate this situation occurring, the impacts of an extended dewatering were not considered in the stream impact caps set for this Plan (**Table 4-2**). If streams are dry for more than one year as a result of DSOD storage restrictions, SCVWD will begin a separate consultation process with USFWS and CDFG and may be required to provide additional mitigation beyond that required by the Habitat Plan. These effects will be minimized through conditions described in Chapter 6 and mitigated through payment of fees (see Chapter 9, *Costs and Funding*) and the Conservation Strategy (Chapter 5).

## Reservoir and Recharge Pond Operations

Effects of reservoir and recharge pond operations are discussed together because operations are conducted in tandem, thus effects of one are also the effects of the other. SCVWD operates eight dams and several in-channel and off-channel groundwater recharge ponds within the permit area to support the water supply needs of Santa Clara County. Operation includes flow management, diversion, delivery, and storage. Operation of these facilities focuses largely on timing reservoir releases to supply water to treatment plants and recharge basins. Several covered species may utilize habitat in streams downstream of SCVWD dams. Species models (**Appendix D**) indicate that California tiger salamander is

known to occur downstream of Anderson and Uvas dams in or near to Coyote Creek and Uvas-Carnadero Creek, respectively. California red-legged frog is known downstream of Anderson and Coyote dams on Coyote Creek, and Uvas dam on Uvas-Carnadero Creek. Foothill yellow-legged frog is known to occur on or near to Uvas-Carnadero Creek downstream of Uvas dam. Finally, western pond turtle is known to occur below Anderson and Almaden dams. All of these occurrences are in the near east and west foothills of the study area, and none of these species are known to occur along streams in heavily urbanized areas with the exception of California tiger salamander which has three occurrences on Communications Hill in San José and one occurrence along Coyote Creek in urban San José.

Direct and indirect impacts may occur through several mechanisms including changes in hydrology and sediment transport, lifecycle disruptions, and introduction of exotic species. In addition, impacts may be exacerbated if DSOD interim storage restrictions are increased to the maximum amount covered under this Plan (see Chapter 2, **Table 2-5**). Each of these impact mechanisms is described below.

## Flow

The purpose of reservoirs and recharge basins is to store water for improved management of long-term water supply needs. The capture and storage of flows results in changes to the natural hydrology of the watershed in. Reservoir and associated recharge operations generally alter local hydrology by reducing stream flow during the wet season when flows would be higher under natural conditions and by increasing stream flow during the dry season when flows would be lower under natural conditions. Flows are reduced during the wet season as reservoirs and recharge basins both capture available water, particularly early in the season. During the dry season when channels would normally have very low flows, flows are above normal as SCVWD releases water from its reservoirs to maintain water in recharge basins and to meet water supply needs. As such, the channel below dams remains wet for more of the year than may be expected under natural conditions. This regulation of flows may be beneficial to covered frog species that utilize habitat below dams due to a more reliable breeding habitat. However, consistent with natural drought conditions, during or immediately following dry years, the volume of flows released may be altered so that target storage levels in reservoirs and recharge basins may be restored. Large release delays, the reduction in release magnitude, and recharge diversions may reduce habitat due to inadequate flows.

During operation as described above, there may be times of rapid increases or decreases in flows; however, SCVWD does generally ramp flows to reduce potential impacts. This may occur due to unplanned maintenance needs (e.g., blow-off of a pipeline, dewatering of a recharge pond, filling a recharge pond). Rapid decreases in flow may result in stranding of eggs and larvae of California red-legged frog. The potential for increased flows are greatest November through April when eggs and tadpoles are most vulnerable to changes in habitat. The potential for decreased flows may occur at any time of the year. Adults may

also be affected, but have more mobility to combat such environmental changes. However, individuals forced to move out of cover in search of new cover may temporarily be exposed to a higher risk of predation. Foothill yellow-legged frogs are thought to be extirpated below major dams in the study area and would therefore not likely be affected by changes in flows due to dam operations.

Flows are also altered by the operation of diversions and in-channel recharge areas. Through the use of inflatable and flashboard dams, in-channel areas are periodically ponded so that flows can be diverted to off-channel recharge areas or infiltrated into the groundwater basin. Ponding has a number of related impacts including the following.

- Emergent and submergent vegetation is flooded, may be covered by fine sediments, and may die off affecting availability of vegetation appropriate for attaching covered species egg masses.
- Cover is reduced for all covered aquatic species.
- At times when the pond would be drained, backwater pockets within the pond basin may create stranding conditions for frogs—adults or larvae.
- All covered amphibians and reptiles may be affected by higher rates of predation due to low velocity flows and lack of cover.
- The diversion ponds support populations of nonnative fish and amphibians which may prey on native amphibians and turtles.

Condition 5, *Avoidance and Minimization Measures for In-Stream Operations and Maintenance*, described in Chapter 6, will minimize these effects.

## Sediment Transport

Reservoirs capture sediment and debris that would otherwise reach the channel below the dams. In particular, reservoirs capture sands and gravels. In addition, large woody debris such as trees and large rock accumulate behind the dam and do not reach the downstream channel. At the same time, a portion of the very fine sediment entering the reservoir remains in suspension and passes through the reservoir into the downstream channels. The result is a combination of altered hydrology and altered sediment transport which affects downstream habitat quality.

The combination of gravel embeddedness and flow changes in the channels below the dams also affects food production and transport. Fine sediment embeddedness inhibits the development of the benthic macroinvertebrates. In addition fine sediments accumulate in low velocity runs and long pools and reduce the general productivity of the aquatic system. Low food production and transport associated with gravel embeddedness and fine sediment accumulations may affect amphibian eggs and juvenile California red-legged frogs, foothill yellow-legged frogs, and western pond turtles (although the presence of exotic species in the affected reaches of channel may preclude viable populations of these covered species in the areas affected).

Increased fine sediments may also cover and thus affect egg laying substrate for amphibians including California red-legged frog. Increases in fine sediment may also affect turbidity (discussed below).

In-channel percolations ponds trap fine sediments during the dry season. Large winter storm events, or the removal of in-channel diversion dams to allow salmonid passage, wash the fine sediments from the in-channel ponds and increase turbidity downstream. Depending on timing, this release of sediment may partially cover egg masses of covered amphibians along the margins of the channels.

## Water Quality

Water quality is affected by reservoir releases and recharge pond and pipeline releases. The operation of these systems can result in changes to turbidity, dissolved oxygen, creation of methyl mercury. Operations also affect sediment transport, but this is discussed in the preceding paragraphs.

Reservoirs have a substantial impact on turbidity, both through changes to sediment transport (discussed above) and algal production. Both reservoirs and in-channel ponds behind diversion dams create heat and nutrient sinks. This combination leads to substantial algal production. High levels of algae result in high turbidity as well as fluctuations in dissolved oxygen. Increased turbidity may inhibit foraging of covered amphibians.

Other causes of increased turbidity include overflow and scheduled releases to channels from reservoirs, recharge ponds, and pipelines. These releases may increase turbidity at and downstream of the release points. These releases may coincide with or be independent of storm events. Scheduled releases from ponds or pipelines do not generally cause extensive turbidity increase except during the first release after an extended period of time during which sediments built up in a pipeline or pond. Suspended sediments from such releases would be anticipated to settle out of the water column within 300–1,000 feet, depending on flow rate.

High levels of algae may also affect dissolved oxygen levels. Given the right conditions, nightly dissolved oxygen levels can drop to levels stressful to covered amphibians. This may be observed during larval and tadpole stages; however, covered amphibians will most likely be able to breathe air by the summer when the effect is most apparent. This is most likely to affect areas of slow-moving pools and runs in downstream reaches and in the in-channel diversion ponds.

Dissolved oxygen levels may also be affected by other aspects of reservoir operation. During normal reservoir operations, water may be released from the cold water pool (hypolimnion) with very low dissolved oxygen levels. These releases affect a short reach downstream, as the flow rapidly aerates as it moves downstream. SCVWD studies indicate that this effect may extend about 100–300 yards downstream of the release point. This reduces the suitability of this reach for all aquatic species. Some dams have facilities for ensuring oxygenation of release water.

Metallic mercury enters reservoirs in runoff from local soils containing mercury and from airborne pollution. Once in the reservoir, mercury sinks to the bottom and, when the reservoir stratifies and produces anoxic conditions, microbes convert the metallic mercury to methyl mercury, which is toxic to fish, wildlife, and humans. Releases from the hypolimnion release methyl mercury which may be taken up by plants and animals downstream, thus accumulating in the food chain. This has the potential to affect covered amphibians.

## **Covered Species Movement**

In-channel structures (dams, diversion facilities, drop structures, and stream gauge weirs) create barriers to upstream and downstream movement of covered amphibians and reptiles. Movement of amphibians may be particularly impeded during low-flow periods. Movement constraints inhibit species ability to disperse and expand ranges. In-channel ponds behind diversion dams also present barriers to movement because these areas are often populated by exotic species that prey on covered species. The effect may be less pronounced at smaller structures that do not preclude adult individuals from utilizing the riparian zone to move through a reach.

## **Exotic Species**

Water supply operations that bring non-local water into the study area (i.e., imported water supplies) introduce and distribute exotic (nonnative) species on an on-going basis, alter habitats in a manner that increases exotic species' competitive advantages over native species, and allows exotic species to prey on native species. Off-channel recharge ponds that are accessible to the general public, through legal or illegal access, also provide a mechanism to introduce exotic species (e.g., through the dumping of pets like bullfrogs). Informal monitoring of percolation ponds by SCVWD has shown that these ponds typically do support large populations of exotic species and very infrequent use by covered species (D. Arnold pers. comm. c). Any new individuals added to these ponds by the general public would contribute to a reservoir population of invasive species and could result in the spread of some invasive species (e.g., bullfrogs, nonnative turtles, and fish) into more natural habitat of covered species breeding ponds within dispersal distance. Conditions described in Chapter 6 that require exotic species to be dispatched when ponds are drained for maintenance purposes could help to reduce local populations of exotic species.

In-channel recharge ponds provide habitat for exotic species such as bullfrogs and bass, which both compete with and prey on California red-legged frogs, foothill yellow-legged frog, and western pond turtles. This reduces the successful occupation of the inundated reaches by covered species using local streams to support various life stages and may also act as a reservoir population that spreads into less affected stream reaches.

## Proposed Operating Rules for Reservoirs

New operating rules for the reservoirs in the northern portion of the permit area may be implemented as part of the proposed Three Creek HCP. New operating rules for Uvas and Chesbro reservoirs may be established through an informal consultation with NMFS and CDFG, a new HCP process, or through formal consultation with NMFS pursuant to Section 7 of the ESA. Implementation of new operating rules for reservoirs are anticipated to include modifications of reservoir releases that would change the area of wetted channel. The focus of these operating rules is to provide enhanced flow conditions and manage cold water habitat for listed fish species. However, changes to releases may also affect species covered under this Plan including California red-legged frog, foothill yellow-legged frog (if it occurs below reservoirs), and western pond turtle. Anticipated changes in operations will reduce early dry-season release rates and increase late dry-season release rates. The effect will be to dry back the downstream reach of the wetted channel earlier than would occur under baseline operations conditions.

In the process, some foothill yellow-legged frogs and California red-legged frogs may become stranded below the zone of sustained flow. This is an early dry-back impact; the channels in question would often be expected to dry back under baseline conditions, because of the high percolation rates in the recharge zone. Any effects are therefore related to the early action to reduce flows. Dry-back may occur before juvenile California red-legged frogs have the ability to leave the channel. In dry years, when the sustainable flow is low, ponded habitat to support frog tadpoles would generally not be available.

As described above, the Implementing Entity will monitor the effects of flow regulation on California red-legged frogs, western pond turtles, and yellow-legged frog populations that occur in streams hydrologically affected by existing dams in the permit area and report to the Wildlife Agencies.

## Recharge Pond Maintenance

Maintenance of recharge basins will range from routine management of vegetation and debris to dewatering and sediment removal to complete reconfiguring of a recharge site on a periodic basis. Sediment removal and reconfiguration require dewatering and substantial disturbance of the pond. Vegetation may be entirely cleared from the edges of the pond and sediment scraped from the bottom of the pond, removing any submerged vegetation in the pond. This type of maintenance has been ongoing at SCVWD recharge ponds prior to implementation of the Plan. Some ponds retain vegetation around the edges during and after maintenance that may provide refugia for covered species during pond maintenance. Other ponds are maintained devoid of vegetation and are unlikely to support covered species before, during, or after maintenance. Although regular maintenance inhibits the development of quality habitat, some recharge ponds are known to support western pond turtles. Western pond turtles using these sites may be temporarily affected by loss of habitat during

maintenance activities, or may be permanently extirpated from the site in cases where suitable habitat is entirely removed. In addition, western pond turtles could be injured or killed by maintenance activities.

Maintenance of in-channel recharge ponds may compact soils in and adjacent to the channel. Depending on the site and time, this may injure or kill amphibians utilizing upland refugia and/or amphibian egg masses. These effects will vary by time of year and extent of activity.

Maintenance will require earthmoving activity and disturbance of soil. If there is precipitation during the construction period or before vegetation is fully established on the affected land, there may be construction-related runoff to the riparian/aquatic habitats at and downstream of the construction site. Runoff from the construction zone may raise suspended sediment levels and increase turbidity resulting in suspended sediments being mobilized and discharged to the channel. In addition, dust may be generated by construction which will disperse beyond the construction area. Finally, proximity of construction equipment to the stream channel may result in fuel, lubricant, and other chemical spills to leak into the channel. Application of avoidance and minimization measures identified in Chapter 6 will greatly reduce the potential for sediment runoff during construction.

## **Dam and Reservoir Maintenance**

Dams and reservoirs operated by SCVWD, County Parks, and the City of San José require routine and corrective maintenance to ensure their proper inspection, functioning, and safety. SCVWD operates 8 dams, as well as Coyote Percolation pond in the permit area. County Parks maintains six dams, one at Sandywool Lake and five at Grant Lake. The City of San José maintains Cherry Flat dam.

Dam and reservoir maintenance activities may include infrastructure maintenance including roads, repair or replacement of dam components and stream flow equipment, vegetation clearing on the dam face, and removal of rodent burrows. Direct impacts associated with activities such as road maintenance and vegetation management are similar to those identified above including permanent and temporary loss of vegetation around facilities.

The net effect of dam face maintenance is to permanently clear the face and abutments of dams of all deep rooted vegetation that could impair the integrity of the dam face or inhibit regular inspection of the dam face for leaks and seepage. While the frequency and extent of covered species use of dam faces is not well quantified, there is a potential for covered species such as California red-legged frog, California tiger salamander, and western pond turtle to use this habitat under current conditions.

## SCVWD Dam Maintenance Program

SCVWD's Dam Maintenance Program is a covered activity under both the Habitat Plan and the proposed Three Creeks HCP. The Dam Maintenance Program describes activities conducted by SCVWD to operate, maintain, and repair water supply facilities including dams, appurtenant structures, and downstream recharge facilities. These activities include the activities discussed above, but also extend to burrow management on the dam face and sediment removal from the reservoir basin.

SCVWD requires that all burrowing animals are to be removed and burrows filled. The effect of these activities is to make the habitat permanently unsuitable for covered species, including covered plant species. Routine and corrective dam maintenance requires filling of burrows to prevent seepage from causing internal dam erosion, which can lead to dam failure. Burrow management involves both efforts to reduce the populations of burrowing animals such as ground squirrels and excavation and re-compaction of any burrows that are found on the dam face and abutments. Therefore, this activity could potentially affect covered species that may be using the burrows as refugia.

Reservoirs require sediment management to maintain reservoir function (e.g., removal of sediment that blocks inlets), and to provide a source of native gravels for downstream aquatic habitat enhancement. This activity requires sediment extraction and hauling at the upstream end of the reservoir and sorting, cleaning, drying, stockpiling at the new gravel augmentation facility described in Section 2.3.3 *In-Stream Capital Projects*. Extraction and hauling require the use of heavy construction equipment.

SCVWD has identified a footprint for each of its dams in which regular dam maintenance will occur. For the purposes of the impact analysis, it is assumed that all natural land cover types will be permanently removed from dams.

Direct and indirect impacts associated with a dewatering event for maintenance purposes and for provision of supplemental water supplies are the same as those discussed in *Dam Seismic Safety Retrofit*, however, impacts may occur at a reduced scale, as full dewatering of the reservoir is not always needed for maintenance activities.

## Non-Routine Stream Maintenance

Most in-stream maintenance in the study area is performed by SCVWD and is currently covered under that agency's Stream Maintenance Program. However, as discussed in Chapter 2, some activities, such as those taking place in serpentine habitats, are considered non-routine and are excluded from the Stream Maintenance Program. Specific non-routine stream maintenance activities covered by this Plan include extensive, one-time vegetation management in the lower Llagas Creek flood control channel, repair and maintenance of canals

(including in serpentine areas), winter season work in canals, invasive vegetation management, maintenance of stream gage and rain gage facilities.

Vegetation management in lower Llagas Creek is expected to reduce overall vegetation in the channel by approximately 50% in perpetuity (once vegetation is initially removed, long-term maintenance to the 50% level will be covered by the Stream Maintenance Program permits). Invasive vegetation management is intended to result in a permanent reduction of invasive vegetation but an increase in native plant species as the site allows.

Repairs to canals including bank stabilization, sediment removal, and vegetation management not otherwise permitted by the Stream Maintenance Program (e.g., in serpentine vegetation areas and during the wet season) are covered under this Plan. Bank stabilization activities may result in both permanent and temporary impacts depending on the size of the project and approach to stabilization used. For example, if rock rip-rap or concrete is required, any natural land covers at the site would be permanently removed. If, however, the repair can be made using compacted earth, then the site would be re-seeded and the site would likely return to pre-project conditions the following growing season. Vegetation management in serpentine communities is likely to result in the permanent loss of such vegetation. Wet season work may result in water quality issue in the canals or the streams to which they connect. Distance to the closest stream and the nature of the canal in the intervening reach will affect the degree to which this potential effect is observed. For example, if the canal is vegetated downstream of the project site, then sediment may be filtered or settled out before reaching the stream connection. Implementation of avoidance and minimization measures described in Chapter 6 will help reduce such potential effects.

Other projects covered under this category are expected to result in temporary reductions in vegetation at project sites.

## **Three Creeks HCP In-Stream Operations and Maintenance**

The proposed Three Creeks HCP describes activities associated with reservoir operations and maintenance, and recharge operations and maintenance. These types of activities will also occur at Uvas and Chesbro dams which are not covered under the Three Creeks HCP but are covered under the Habitat Plan. As such, impact mechanisms for these types of activities are discussed for the entire Habitat Plan study area in the following sections.

### **Three Creeks HCP Conservation Program**

As discussed above, the proposed Three Creeks HCP includes a suite of activities to enhance conditions for steelhead trout and Chinook salmon, while maintaining use of local watersheds to meet the water supply needs of northern Santa Clara

County. The following actions include components of the Three Creeks HCP Conservation Program that are in-stream operations and maintenance activities.

### **Reservoir and Recharge Re-Operation**

The proposed Three Creeks HCP Conservation Program includes modifications of reservoir and groundwater recharge operations to enhance flow, temperature, and water quality conditions in the channels downstream of reservoirs to promote better fish habitat. These activities will be implemented at Coyote Creek, Upper Penitencia Creek, and Alamos Creek (Almaden Reservoir and the Alamos Diversion).

These actions are intended to mimic natural conditions in support of salmonids. They are also expected to have beneficial effects on covered species for this Plan. More natural flow patterns, including large flushes of water, may clear fine sediments from stream channels and vegetation, thus improving egg laying substrate for amphibians. In addition, flow management is expected to support benthic macroinvertebrates which form the base of the stream system food chain.

### **Upper Penitencia Creek Management Program**

The Upper Penitencia Creek Management Program requires specific timing of water supply operations including reservoir releases. These types of activities are discussed above under *Proposed Operating Rules for Reservoirs*. This activity may also require replacement or removal of existing infrastructure. This type of activity could result in impacts similar to those described above for minor construction activities in streams. Potential impacts may include permanent and/or temporary impacts to riparian vegetation and ground disturbance.

### **Supplemental Flow Program**

SCVWD has developed a program to provide supplemental flows to the base of Anderson and Calero Main dams to ensure that the conservation strategy flow targets for summer flow targets can be reliably met under a variety of conditions, such as implementation of DSOD Interim Storage Restrictions, short-term equipment failures, and scheduled and unscheduled maintenance that requires reservoir dewatering. Temporary pipelines will be installed prior to the initiation of a dewatering event and when supplemental flows are required. Temporary pipelines will be removed when supplemental flows are no longer needed.

The source of supplemental flows varies from reservoir to reservoir and provision of flows may require installation of a temporary pipeline, use of trucked water, bypass of flows from upstream of the reservoir, use of imported water, or installation and use of a new groundwater pumping system including new pipelines. Imported or recycled water will only be used if it can meet temperature and water quality criteria. Although uncommon, it is possible that imported water contain exotic fish or other invasive species. While many of these exotic species already exist below the dams, increased numbers of exotic species may increase the level of predation on covered species.

New infrastructure installed to provide supplemental flow will be installed along existing roads and pipelines within the disturbed footprint, or within the Dam Maintenance Program area of routine maintenance. Therefore, no additional

impacts to land cover are expected as a result of supplemental flow infrastructure installation.

### **Monitoring Program**

SCVWD will conduct monitoring of species covered by the proposed Three Creeks HCP. The monitoring program will include the same types of activities described below in Section 4.3.7 *Conservation Strategy Implementation*, subheading *Activities within the Reserve System*.

## **4.3.4 Rural Capital Projects**

Rural capital projects (those capital projects occurring outside the planning limits of urban growth) are likely to have the same types of direct, ground-disturbing impacts as development within the planning limits of urban growth. However, like rural development, the severity of impacts associated with rural capital projects is likely to be greater than impacts associated with urban projects because urban projects typically occur in areas that are already degraded. A discussion of direct and indirect impacts associated with the major types of rural capital projects covered by this Plan is presented below.

### **Rural Transportation Projects**

Most of the road projects covered by this Plan are expansions or improvements of existing roads, highways, and intersections. Additionally, VTA plans to install a parallel set of tracks alongside the existing Caltrain route from San José to Gilroy. The County has identified three new roads in the permit area outside of the planning limits of urban growth: a connection of DeWitt Avenue to the West Edmundson Avenue / Sunnyside Avenue intersection near Morgan Hill, a connection on Center Avenue between Omar Avenue and Buena Vista Avenue northeast of Gilroy (requires a new stream crossing), and a connection between Center Avenue and Hill Road across Maple Avenue immediately south of Morgan Hill. VTA is planning to construct one new connector road as part of the U.S. 101 Improvement Project (Monterey to SR 29). This road would be an extension of Santa Teresa Boulevard from Castro Valley Road to U.S. 101 at the SR 25 interchange and requires a new stream crossing. This connector road is just outside of Gilroy's planning limit of urban growth. These projects are anticipated to have permanent, direct impacts on natural land cover types, and therefore on covered species.

Implementation of these projects would result in permanent impacts on land cover within the footprint of each project. Indirect impacts may also occur as a result of expanded roads. In the absence of designs to minimize these effects, wider highways and freeways, already difficult for wildlife to navigate, will intensify road crossing hazards for wildlife and result in increased vehicular strikes. The disruption of wildlife movement results in increased habitat and population fragmentation by creating more extensive and obstructive barriers between populations and habitats. Expanded roads that support a higher volume

of traffic may also result in increased runoff of car waste (e.g., oil, grease, radiator fluid) and debris (e.g., tires, litter, car parts), which may be hazardous to wildlife. Increasing the total amount of roads, even dirt roads, can lead to increased sediment in the watershed from concentration of hillslope and surface runoff, which causes higher peak flows and contributes to bank erosion. In addition, expanded roads can create substantial noise and physical disturbance that may disturb or disrupt covered species far from the road. Finally, as discussed above in Section 4.3.1 *Urban Development* increases in vehicular traffic will result in increased nitrogen deposition in areas adjacent to roadways.

Road expansion projects adjacent to cultivated agricultural areas are expected to have less severe direct and indirect effects than road projects adjacent to natural land cover types because the habitat value of cultivated agriculture is lower. Measures to avoid and minimize the impacts of covered transportation projects, including design measures for new and expanded rural roads, are described in Chapter 6.

## South County Airport Expansion

Permanent and temporary direct impacts related to the proposed expansion of the South County Airport as identified in the South County Airport Master Plan are similar to impacts of other capital projects that result in the conversion of non-developed land–cover types to developed uses.

Indirect impacts associated with expansion of the South County Airport include increased noise due to higher usage. Lighting improvements proposed in the master plan may also have indirect impacts on covered species if bright lights are used at night. However, the South County Airport is located in a rural residential area just west of U.S. 101. While ruderal and annual grassland habitats on this project site and in surrounding areas support foraging habitat for many raptor species, the indirect impacts associated with increased noise and/or lights are expected to be minimal. Though suitable habitat for western burrowing owl is present in and around the South County Airport, there are no recent occurrences of western burrowing owls breeding at the site. If the species colonizes the airport, expanded operations may have indirect effects through increased lighting and noise. These potential indirect effects are not anticipated to preclude use by burrowing owls, as demonstrated by the continued use by this species of the San José International Airport nearby, which has much greater levels of aircraft activity and generates much more lighting and noise than would be generated by the South County Airport expansion. Should this species be documented at the site prior to airport expansion, the conditions on covered activities, described in Chapter 6, would be employed to minimize effects.

Expansion of the airport runway is not anticipated to result in increased bird strikes; however, increased use of the airport (i.e., more flights) may result in increased bird strikes. Approximately 100 new hangars were completed at the South County airport in 2005. The master plan identifies a potential future increase in the number of hangars, tiedowns, and fixed base operators that can be accommodated at the airport. Such expansion is likely to lead to increased use of

the airport as a result of more pilots choosing to base their planes at the airport as the population and the abundance of commercial and industrial activities around the airport grow. The extent to which bird strikes may increase is unknown at this time. As noted in Chapter 2, the NEPA/CEQA environmental compliance documents for the proposed master plan have not yet been prepared. However, the number of aircraft based at the South County Airport has almost doubled in the past 3 years, and a significant change in the number of bird strikes has not been recorded. Moreover, there have been no reported bird strikes at the airport in the last 8 years (Honaker pers. comm.). It is anticipated that the potential for increased bird strikes will be evaluated in the environmental compliance documents and avoidance measures identified if it is determined that an increase in bird strikes is likely to occur.

## **Kirby Canyon Landfill Development**

Direct, permanent impacts associated with the Kirby Canyon Landfill development in Fill Areas 3 and 4 include loss of natural land cover types in the footprint of the fill areas and of supporting facilities including roads and sedimentation basins. Temporary impacts may occur in areas where the ground is disturbed during landfill operation activities but revegetated to pre-project or ecologically improved conditions within the time allowed for temporary impacts.

Indirect impacts associated with noise and light are not expected to increase over the current level since the Plan assumes that the amount of waste deposited to the landfill (also called the “disposal rate”) will remain consistent with current operations. Indirect impacts could occur if the landfill lining fails, and water that has come in contact with waste (called “leachate”) enters the natural ground or surface water system. However, considerable technological efforts are used to prevent leachate from coming into contact with groundwater, and potential impacts are both regularly monitored and addressed by state over-sight agencies. Overall, landfill design and construction methods are sufficiently advanced that a significant indirect effect is unlikely to occur. If it does occur, the mechanism to stop and repair the impact is in place through agency regulation (i.e., the Regional Water Quality Control Board). This Plan does not authorize take associated with a failure of the landfill lining.

## **Off-Channel Groundwater Recharge Ponds**

Several water supply projects are planned in the permit area during the permit term. These include the development of groundwater recharge sites on the valley floor in the Coyote Valley and around San Martin; and infrastructure, such as access roads and conduits, required to support these projects. Implementation of these projects would result in permanent impacts on land cover within the footprint of each project (i.e., loss of undeveloped land cover types to new structures). As is true of other capital projects, some temporary impacts outside the project footprint are expected during construction due to access and staging

needs. Direct impacts of operating new off-channel groundwater recharge basins include potential entrainment of covered aquatic species in outtakes from creeks.

Increases in the number of groundwater recharge sites may result in an increase in groundwater levels, and thus there is a potential to affect local streams by increasing in-channel flows. This effect is only expected to be observed during winter and spring when surface water is most available and SCVWD is actively working to recharge groundwater basins. Any increase in in-channel flows may help to offset the reduction in winter flows resulting from the operation of reservoirs and recharge ponds described in Section 4.3.3 *In-stream Operations and Maintenance* subheading *Reservoir and Recharge Pond Operation*. However, changes to groundwater levels due to recharge that occur within the same hydrologic unit (e.g., the south county Pajaro River basin) may result in no net change in average groundwater levels over time if the recharge and extraction are occurring at equal levels. This will likely be the situation in an average water year. Wet water years may experience high levels of recharge with reduced pumping and stream flows could increase (consistent with the natural process of a wet water year). Dry water years may result in reduced availability of water supplies, and thus less groundwater recharge will occur, more consistent with existing conditions where no recharge ponds currently exist.

Indirect effects of groundwater recharge basins may result from new ponds supporting nonnative predators of covered species. This potential affect could be exacerbated if the new ponds provide habitat to covered species (e.g., vegetation around ponds) and recreational access to the general public. As discussed above, ponds that allow recreational access may be targets for illegal dumping of invasive species (e.g., bass or red-eared slider turtles) that could prey upon covered species using the ponds.

It is unlikely that these projects would result in unanticipated population growth, because these projects are planned to meet currently anticipated demands.

Other indirect impacts may result from the construction of new access roads in areas of little development. As discussed above, new roads in rural areas can cause habitat fragmentation and obstruction of wildlife movement corridors. However, these factors are unlikely to be an issue for three of the four proposed groundwater recharge ponds, because the ponds are located on the valley floor in Morgan Hill and San Martin in an area that is already urbanized or rural residential. The fourth pond is planned for the Coyote Greenbelt in an agricultural area. Because this area is already developed for agriculture and has development both to the north and south of it, it is likely that existing roads may be used to access the site and that habitat and connectivity will not be further affected.

## Park Facility and Trail Construction

The cities, County, and Open Space Authority will construct new park facilities and trails in the permit area within the permit term of the Plan. Each of the three cities has developed a master plan for parks and trails within respective planning

limits of urban growth. The County has also developed master plans for each of its parks for which new facilities and trails are proposed (see Section 2.3.5 *Rural Capital Projects* for a full list of master plans).

Major components of developing new parks include the construction of a park entrance (if one does not exist), access roads, staging areas, parking areas, and new trails. Construction of these facilities will have permanent and temporary direct impacts similar to those of other capital projects (i.e., permanent conversion of land cover beneath the footprint of the project, with temporary impacts occurring in a buffer zone around the project site). Ground disturbance due to construction would likely increase the spread of nonnative species, especially in areas not previously disturbed. New trails will be sited to avoid streams and adjacent riparian vegetation whenever possible in accordance with the conditions identified in Chapter 6. However, some new trails will require creek crossings that may result in removal of riparian vegetation and construction of bridges. While some temporary impacts on streams are likely to occur during project construction, many impacts can be avoided through implementation of avoidance and minimization measures and other mitigation measures. In addition, permanent impacts on streams can be avoided through use of appropriate design of crossings (e.g., free-span bridges).

New trails may also require construction materials (e.g., rock, soil, clay) that are taken from borrow sites. Specifically, County Parks anticipates using up to 3 acres for development of borrow sites. This amount of borrow would be used across all parks throughout the permit term. Whenever possible, borrow sites will be located so that they can be used to create habitat for covered species (e.g., a borrow site can be used as a created pond for California tiger salamander). In these cases, development of borrow sites will result in the conversion of one land cover type (e.g., grassland) to another land cover type (e.g., pond). Areas around the borrow site may be temporarily disturbed during borrow site construction.

New park facilities will include parking areas, both unpaved and paved, and new trailhead facilities for multiple trail uses which may also include construction of restrooms, fencing, railing, boundary controls, kiosks, and access roads to the trailheads. Whenever possible, these facilities will be developed in existing disturbed areas and are sited to avoid sensitive land covers. Streams and riparian land covers will be avoided entirely. However, some direct loss of non-developed land covers is expected.

Development of new large recreational facilities such as golf courses will have similar impacts as described for urban development. County Parks anticipates that development of such large facilities will occur in valley floor areas in urban or rural residential settings, thus these facilities are more likely to affect urban and agriculture natural communities as opposed to other less developed natural communities and land covers.

In addition to developing new recreational facilities, County Parks anticipates conducting restoration and resource management activities on lands that are not included in the Reserve System. Restoration and resource management projects

on these lands will have similar impacts to those described below under Section 4.3.7 *Conservation Strategy Implementation*.

Indirect impacts related to development of trails and new trailhead facilities are largely related to ongoing anticipated use of trails and facilities, as well as to inappropriate use of trails (e.g., off-trail hiking, illegal dumping). Indirect impacts related to public use of regional parks and open space as described above in Section 4.3.1 *Urban Development* may result from improved trail access to new open spaces, including areas in the Reserve System. These impacts may be minimized through supervision of regional trail use, education of open space users, and restricted or managed access to open space. Indirect impacts may also be related to increased noise in areas where trail head facilities are located, increases in the amount of trash that escape into natural areas and into local streams, and increased use by pets which may harm or harass covered species. Development of fishing ponds and stock ponds may increase the presence of nonnative species like bullfrogs and red-eared sliders that predate on and compete with covered species.

Up to 40 wells or spring boxes may be constructed in County parks. These wells and spring boxes have the potential to indirectly impact seeps, springs, stream flow, and riparian vegetation health. If a well is placed in such a manner that it draws down groundwater levels along a reach of stream, that reach may experience reduced flows. Reduced flows can occur either from a reduction in groundwater supporting the streamflow or from the more rapid percolation of flows from the upper watershed into the channel substrate, filling the space once occupied by groundwater. Reduced flows may degrade aquatic habitat or prevent riparian vegetation from obtaining adequate water. Lowering of the groundwater table could also result in the drying up of seasonal wetlands or seeps. The wells and spring boxes installed in County parks are not expected to have an effect on groundwater level due to the low level of extraction required to support ponds and because wells will be sited to avoid impacts to aquatic land covers. Wells that are found to result in adverse effects to adjacent streams will be decommissioned and sited elsewhere.

A beneficial effect of developing trails in suburban or urbanizing areas, such as the Coyote Valley, is that trails (e.g., Coyote Creek trail within the Coyote Creek Parkway) have been documented to facilitate nocturnal movement of wildlife such as American badgers, bobcats, Tule elk and other species within the riparian corridor and eventually across the valley floor.

## 4.3.5 Rural Operations and Maintenance

Rural infrastructure requiring maintenance includes trails, roads, buildings, and park trailhead facilities. Maintenance activities are generally expected to have minimal permanent or temporary direct impacts because the vast majority of these activities occur within the disturbed roadbed or shoulder or in other areas that have been previously disturbed.

## Utility Maintenance

Existing utility lines, including pipelines, will likely require maintenance and possibly replacement during the permit term. Most of these lines will be underground and may require excavation to access the lines. Direct impacts include ground disturbance resulting from excavation, access, and staging. All natural areas disturbed by utility maintenance activities will be returned to pre-project or ecologically improved conditions in the time allowed for temporary impacts and in accordance with the conditions in Chapter 6 or the impact will be considered permanent. Indirect impacts associated with this activity are similar to those of other ground-disturbing work; such impacts can be avoided and minimized with use of appropriate avoidance and minimization measures described in Chapter 6.

## Facility Maintenance

Facility maintenance refers to maintenance of existing facilities such as buildings, roads, trails, parking lots, airport property, and so on. A large component of this maintenance is vegetation management. Vegetation management along road shoulders and rights-of-way may have the potential to disturb a narrow strip of habitat for covered species and possibly to injure or kill individuals that occur in this habitat. Impacts can be associated with accessing areas, clearing vegetation in order to perform maintenance activities, or managing vegetation to prevent overgrowth and for fire prevention and management. Impacts may also be associated with application of fertilizers or pesticides that are commonly applied to landscaped areas or turf maintained for public parks, play fields, and golf courses. Over application of fertilizer and pesticides may result in these substances washing off the target vegetation and entering local streams where it may cause indirect impacts including algal blooms or mortality of non-target species, including covered aquatic species. Impacts related to vegetation management may be permanent or temporary (e.g., trees completely removed may not reestablish, while mowed vegetation will likely regrow in a short time). Maintenance work involving minor grading or soil disturbance could cause increased sediment discharge into watercourses. However, implementation of standard avoidance and minimization measures should help reduce temporary impacts of such activities.

SCVWD maintains off-channel groundwater recharge ponds. Direct impacts on wetland vegetation around the perimeter of the ponds may result from accessing basins for sediment removal or to clear the areas around intake and outlet structures. Impacts may also occur from annual dry-cycling (when the pond is drained and maintained in a dry condition) which can eliminate aquatic species and standing biomass. This maintenance would adversely affect covered species using the pond; however, it is also beneficial as it eliminates any exotic species or vegetation using the pond. Elimination of exotics also helps slow the spread of exotic species from ponds into surrounding natural areas. These impacts are expected to be minimal and would equal approximately 20 square yards at each facility. Facilities would be maintained approximately once every year (J. Abel

pers. comm.). SCVWD also maintains 39 rain gages throughout the permit area, mostly in the upper watersheds and away from streams. Maintenance activities focus on vegetation clearing to maintain the catch of the gages. In addition, some vegetation clearing may be required to access gages from roads or trails.

The County of Santa Clara conducts maintenance of its facilities including, but not limited to, medical facilities, correctional facilities, shelters, shooting ranges. Some of these activities may directly affect non-developed land covers or result in indirect effects similar to other effects described in this section (e.g., temporary loss of natural land covers, temporary increases in light and noise pollution).

County Parks conducts maintenance of infrastructure such as trails, roads, parking lots, and offices that may include treatments such as mowing for fuel breaks. Such maintenance could result in direct temporary impacts, especially if work is conducted on trails through sensitive land cover types. However, as a natural resource management agency, County Parks implements avoidance and minimization measures and strives for zero impact in all its operations. Any impacts on upland land cover types resulting from operations and maintenance in County parks is likely to be minimal.

Vegetation management conducted during the migratory bird breeding season could result in the loss of habitat for migratory covered birds such as western burrowing owl, least Bell's vireo, or tricolored blackbird. The Habitat Plan requires that vegetation management occur outside the migratory bird nesting period, or surveys will be conducted before clearing to avoid these impacts (see Chapter 6, Section 6.3, subheading *Condition 1 Avoid Direct Impacts on Legally Protected Plant and Wildlife Species*).

Rodent, pest, and invasive plant species abatement activities may be conducted for facilities maintenance. Animal traps, pesticides, and herbicides may be used to control rodents, pests, and invasive plant species. Pesticides and herbicides have strict handling and application requirements; however, potential indirect effects include potential effects on non-target species by applied chemical treatments. For example, pesticide placed for rodents could affect California tiger salamanders seeking refuge in rodent burrows. These potential effects will not be covered under the Section 10(a)(1)(B) permit.

## Pond Maintenance

Pond maintenance outside the Reserve System will be implemented consistent with the covered activity description in Chapter 2 and conservation actions for pond maintenance in Chapter 5. Impacts will be consistent with those described below in Section 4.3.7 *Conservation Strategy Implementation* subheading *Activities within the Reserve System*.

## SCVWD Pipeline Maintenance Program

SCVWD developed an EIR for the Pipeline Maintenance Program that identifies direct permanent and temporary impacts of a variety of activities, including staging, off-road access, pipeline drainage, excavation, and repair. Impacts may affect aquatic resources and riparian or upland natural communities. Direct impacts associated with staging are similar to other staging impacts described above. Off-road access may cause temporary impacts on upland vegetation around accessed pipelines or on riparian vegetation where creek access points are established so that blow-off (pipeline drainage) can be directed to local watercourses. Off-road access may also result in direct mortality or injury of covered species. These effects will be minimized because SCVWD will use existing access roads wherever possible and will limit off-road travel to disturbed areas. Off-road travel will avoid sensitive communities such as wetlands and known occurrences of covered plants. Blow-off may cause disturbed soil and vegetation at blow-off locations, increased flows in the receiving channel, and channel erosion. Excavation may be required to access buried pipelines in upland or riparian areas.

SCVWD will utilize avoidance and minimization measures to reduce the level of impact caused by these covered activities (see Chapter 6).

Indirect impacts associated with the Pipeline Maintenance Program include temporary increases in dust and noise around project areas. Off-road vehicle travel could also result in the spread of nonnative invasive plants. Other indirect impacts may result from temporarily altered flows downstream of the site where pipeline water is discharged. Changes in flow could result in impacts similar to those described in Section 4.3.1 *Urban Development*. However, the scale of impact would likely be much smaller due to the frequency of maintenance (no more than 10 blow-offs per year and maintenance of up to five pipelines per year) and the implementation of avoidance and minimization measures. Additional indirect impacts could occur if blow-off water is a different temperature than stream flow, causing a temperature fluctuation in the stream.

### 4.3.6 Rural Development

Rural development, or exurban development, is loosely described as low-density development at or beyond the rural-urban fringe (Glennon and Kretser 2005). Direct and indirect impacts related to rural development are similar to those discussed above in Section 4.3.1 *Urban Development*. Many important causes of habitat loss and fragmentation stem from changes of land use on private lands, especially conversion of agricultural lands to residential development (Theobald 2003). Development of homes and associated structures (e.g., roads, garages, barns, stables, vineyards) and non-residential development (e.g., telecommunications facilities, agricultural structures, rural commercial development, recreational use areas) in rural areas, including ranchland, will have direct impacts on natural land cover types in areas where structures and infrastructure are built. While the footprint of development per acre may be

lower, the impact of habitat fragmentation is higher in rural areas than in urban areas, because the existing landscape is generally less disturbed prior to project construction. From an ecological perspective, this dispersed pattern of development effectively maximizes the individual influence of each home on the land (Lenth et al. 2006).

Moreover, private roads and driveways are often required to access rural homes; such roads further fragment the landscape and potentially degrade movement corridors for covered species. New roads can also create new hazards or barriers to other native species that depend on long-distance dispersal and movement for survival (e.g., American badger, Tule elk, black-tailed deer, bobcat, mountain lion). Finally, roads and other linear projects create dispersal corridors for nonnative plants. Exurban development tends to result in an increase in generalist wildlife species commonly found in urban areas (e.g., opossum, skunk, coyote, American crow), and a decrease in specialized or human-sensitive species (Glennon and Kretser 2005; Lenth et al. 2006). Such trends decrease the health of natural communities and could result in harm of covered species. Cumulatively, these rural development projects fragment the landscape and make it more likely that wildlife populations will become segmented and isolated.

Impacts from light pollution and noise may also be more significant when introduced into areas where they did not previously exist. Noise from vehicle traffic can disrupt nesting birds and typical movement patterns of terrestrial animals. New sources of light in formerly unpopulated areas can affect the ability of some species—especially birds, bats, and many species of insects—to navigate at night.

In addition to residential development, industrial private development projects include the Z Best Composting facility, the Pacheco Pass Landfill, and Freeman Quarry. The County has identified three public projects that may require ground disturbance: James Ranch and Holden Ranch (separate facilities but physically adjacent), the Muriel Wright Center, and the Mariposa Lodge and Sheriff's Firing Range (separate facilities but physically adjacent). These activities would also result in conversion of natural or semi-natural land cover types to developed land cover types and result in similar impacts as described for other rural development projects. The Mariposa Lodge and Sheriff's Firing Range facilities are located in serpentine bunchgrass grassland and implementation of this project is expected to affect up to 27.5 acres of this land cover type.

Indirect impacts on natural land cover and covered species may result from an increase in impermeable surfaces; as described above in Section 4.3.1 *Urban Development* such increases can result in impacts on streams. Additional indirect impacts on streams could result from the use of septic systems. If leach fields are sited too close to waterways, the nutrient-rich liquid exiting the septic tank may travel into the waterway and cause abundant algal growth, degrading water quality. Leach field seepage may also alter the native vegetation if nutrient-rich water reaches the surface. Within the study area, water quality impacts may arise from the use of pesticides and/or fertilizers on small "hobby" orchards or vineyards, or from horses or other livestock that are kept close to streams. Similarly, new agricultural facilities, such as commercial stables, equestrian

event facilities, and wineries, may also produce waste that is rich in nutrients or other potential pollutants for local streams. In addition, exposed soils common to vineyards and equestrian or livestock enclosures are potential sources of erosion and sediment input to streams. This is exacerbated in cases where vineyards are developed in steep terrain. Existing County ordinances, as well as strict NPDES permits overseen by the Regional Boards, require many avoidance and minimization measures targeted at protecting water quality in local streams.

Existing land use restrictions and requirements also substantially limit the footprint and extent of rural development. For example, almost all of the areas intended to be incorporated into the Reserve System (see Chapter 5) are large land holdings designated as Hillside or Ranchland land uses under the County General Plan. In these areas, the maximum development density allowed is one residence per 20 to 160 acres, based on the average slope of a parcel. Subdivision of sites designated Hillside or Ranchland seldom occurs and this pattern is not expected to change during the permit term due to the physical challenges of development in most of the study area. Under County policies, most subdivision proposals for Hillside parcels are required to cluster future development and preserve a minimum of 90% of the site as open space. If suitable (as determined by the Implementing Entity), these large set-asides could be incorporated into the Reserve System. County policies and regulations also require that grading be minimized in Hillside and Ranchland areas through the site design process, which emphasizes compact development. These land-use restrictions help to minimize the effects of rural development on covered species and natural communities.

### 4.3.7 Conservation Strategy Implementation

Activities related to the implementation of the conservation strategy that may result in impacts are separated into two groups: activities that will occur within the Reserve System and activities that will occur outside the Reserve System. Both groups of activities are described below.

#### Activities within the Reserve System

Activities within Plan reserves are expected to have a net benefit on all covered species (see Chapter 5 *Conservation Strategy*); nevertheless, some conservation actions may have temporary or limited permanent adverse impacts on covered species, resulting in take. In other cases, activities that are designed to benefit one or more covered species may harm another set of covered species. However, the Plan Reserve System is designed to be large and diverse enough to ensure that the net effect of all reserve activities is beneficial to all species across the system.

Some habitat enhancement, restoration, and creation activities may temporarily and adversely affect wildlife habitat. For example, planting emergent vegetation in stock ponds could temporarily disturb amphibians occupying the pond.

Periodic dredging of ponds to maintain pond capacity and habitat quality may also have temporary adverse effects on pond species. The cleared bank conditions that precede establishment of native riparian plants can also trigger rapid establishment of weedy or undesirable aggressive species if these species are not controlled at the site. Man-made livestock pond removal will be only undertaken if removal improves the functional values of the site or if the pond is a safety hazard. If such actions are taken, the Implementing Entity will replace the pond lost with a new pond in another location in the Reserve System consistent with the requirements of the conservation strategy. Naturally formed ponds will not be removed.

Another example of habitat enhancement actions that may temporarily and adversely affect wildlife habitat is road removal. Road removal will only be undertaken if the benefits are determined to outweigh the adverse effects. For example, it may be appropriate to remove a road that is poorly sited such that it is contributing to localized erosion. It may not be appropriate to remove a road that is not causing other adverse impacts. In such cases, instead of removal, a road may simply be closed off from access.

Monitoring and research activities required by the Plan (see Chapter 7 *Monitoring and Adaptive Management Program*) may also disturb wildlife. For example, in order to determine the presence of some covered species (e.g., California red-legged frog tadpoles), individuals must be handled by a qualified biologist. Such handling constitutes harassment—a form of take—under ESA and requires authorization. All biologists conducting monitoring under the Plan (i.e., Implementing Entity staff or their consultants) will be covered for their monitoring activities should any take occur. See Chapter 6, Section 6.8.5 *Item 5: Results of Applicable Species Surveys and Monitoring* for details on biologist certification to conduct monitoring activities. Translocation activities, which must be coordinated with and approved by the Wildlife Agencies, could also cause take through injury or loss of individuals due to capture, handling, transportation, release, and/or the inability of the individual to find new shelter.

Terrestrial management activities may also disturb or inadvertently harm covered species. For example, fuel breaks must be created in key areas of the Reserves to minimize the risk of wildfire and to protect structures and adjacent lands. Creating and maintaining these fuel breaks may have minor adverse effects on grassland-dependent species such as western burrowing owl and Bay checkerspot butterfly. Prescribed burns will be designed to provide long-term net benefits to natural communities and covered species. However, these burns may result in take of some covered species during the burn. For example, burns in serpentine grassland may adversely affect serpentine covered plants or take Bay checkerspot butterfly larvae. Prescribed burns in annual grassland may temporarily adversely affect western burrowing owl (although burns may also provide new sources of prey to these species, such as insects escaping flames and smoke). Wildfires may have similar adverse effects on covered species as prescribed burns, but these effects may be more severe due to the greater size and intensity of wildfires.

The conservation strategy calls for installation of up to 49 wells to support ponds in the Reserve System. Potential indirect effects related to the installation of

groundwater wells were previously described in Section 4.3.4 *Rural Capital Projects* subheading *Park Facility and Trail Construction*. The groundwater wells installed to support ponds in the Reserve System are not expected to have an effect on groundwater level due to the low level of extraction required to support ponds and because wells will be sited to avoid impacts to aquatic land covers. Wells that are found to result in adverse effects to adjacent streams will be decommissioned and sited elsewhere.

Recreational or management facilities built and maintained within the Reserve System could result in a small amount of habitat removal. Facilities will be sited and built to avoid or minimize their effects on covered species, but a small amount of take may nevertheless occur. The Permittees are covered for incidental take of covered species resulting from public use within the permit area, inside or outside of the designated Reserve System, provided that usage is consistent with park management plans and the guidelines of this Plan. Although the permits do not cover incidental take for private individuals, recreational activities allowed on reserves are expected to have some minor impacts on covered species. Heavily used trails would result in some permanent indirect impacts on wildlife habitat connectivity. Since wildlife is most active at dawn and dusk or at night, disruptions of wildlife movement are not anticipated to be significant. Trails can fragment otherwise intact landscapes and can also facilitate predator movements and invasion by nonnative animals (e.g., feral cats, dogs, pigs). Trails are often a source of invasion by nonnative plant species that are transported into the reserve by trail users. As described in Chapter 5 *Conservation Strategy* recreational uses will be limited to low-intensity activities such as hiking, wildlife observation, horseback-riding and non-motorized bicycling. Any new trails will be carefully sited and maintained to minimize the disturbance of habitat and wildlife, as well as sited and maintained to avoid disturbance of cultural and archaeological resources within reserve areas. Despite these restrictions, some take in the form of harassment associated with recreational activities is expected to affect covered species that are sensitive to human disturbance.

Implementation of the Plan conservation strategy could also affect covered plants through habitat enhancement or restoration and creation which could result in removal of or degradation to species habitat. Plant populations in the Reserve System could also be temporarily affected by management activities such as prescribed burning or livestock grazing although the long-term effects of these activities are expected to be positive. The Plan also includes many types of monitoring which can occasionally have impacts on individual plants in the form of trampling or soil disturbance. In all of these cases, the benefits from Plan implementation are expected to greatly outweigh any negative effects of implementation on the covered plants.

In addition to the conservation actions described above, it will also be necessary for the Implementing Entity to install or replace infrastructure in the Reserve System including signage, fences and gates, field facilities, dirt roads, paved roads, vehicle bridges, and culverts in order to conduct required management and monitoring activities. These activities would have permanent impacts similar to other covered activities. Temporary construction impacts are likely as well. All

facilities within the Reserve System will be sited on already disturbed areas to the extent possible and in areas that minimize effects on covered species. All activities will comply with the conditions on covered activities in Chapter 6.

## Activities outside the Reserve System

The Plan proposes to conduct stream and riparian restoration and other conservation actions, including removal of invasive weeds (e.g., *Arundo donax*), that will occur outside the Reserve System. As discussed in Chapter 5 (Section 5.2.3 *Reserve System*), these actions will require agreements to be reached with landowners regarding the installation and maintenance of the conservation actions. The Plan also calls for management of western burrowing owl, and the possible creation of a Coyote ceanothus occurrence outside of the Reserve System.

Stream and riparian restoration activities may result in temporary direct impacts during construction including loss of vegetation during restoration project construction, or removal of invasive weeds. All areas that experience reduced vegetative cover during construction will be replanted and monitored, in accordance with Chapter 7, to ensure that riparian vegetation reestablishes as part of the restoration project. As with implementation of conservation actions inside the Reserve System, these conservation actions are expected to have a net benefit on covered species that utilize stream and riparian habitats.

Burrowing owl management actions could occur on managed lands outside the Reserve System. These activities will likely occur on sites that have been previously impacted (e.g., capped landfills) as well as at sites that are more natural in nature (e.g., foothill grasslands). Burrowing owls prefer nesting sites with ample burrows, low slopes, and short grass. As such, a key management action will be to mow or graze management sites. It is not expected that this management will affect many other covered species as burrowing owl nesting habitat does not extensively overlap with habitat of other Plan covered species. However, if areas in the foothills are managed for owls, there is the potential for these sites to be also used by California tiger salamander or California red-legged frog for refugia. These species, as well as burrowing owl, may be temporarily affected by management activities due to presence of people, livestock, or equipment.

The Plan allows for the creation of new Coyote ceanothus populations outside the Reserve System. Coyote ceanothus is a large, woody shrub that often grows in dense, monotypic stands. Because of the possibility that a new creation could displace serpentine grasslands, siting of a created occurrence will minimize the potential for displacement of habitat for other covered species. The Implementing Entity will develop a plan with the Wildlife Agencies for the occurrence creation. The plan will include measures to avoid other covered species.

Monitoring for covered species and natural communities will also occur outside the Reserve System in the situations described above. Some monitoring actions

may result in temporary harassment of covered species in order to identify, measure, or tag individuals.

## Neighboring Landowner Assurances

Because the conservation strategy aims to increase populations of covered species through habitat enhancement, restoration, and creation, certain species may disperse out of the Plan reserves where active management is undertaken and onto neighboring private lands. This Plan includes a Neighboring Landowner Assurances program to protect landowners in the permit area near reserves from the regulatory consequences of special-status species dispersing onto their property. Private lands within 1 mile of the Reserve System that are actively used for agricultural purposes (e.g., crop production) will receive take coverage under the Plan. The rationale for the 1 mile radius is described below. Coverage for nonagricultural lands is unnecessary because take coverage is already provided for urban and rural development; see Chapter 2.

Coverage will be provided to agricultural operations only for take beyond the baseline condition that existed prior to the establishment of the neighboring Reserves and only for ongoing and routine agricultural activities<sup>5</sup> on lands enrolled in the Neighboring Landowner Assurances program. Participation in this program is voluntary and landowners will be able to opt in for coverage. Coverage under the Neighboring Landowner Assurances program expires when the permits expire. See Chapter 10, Section 10.2.7 *Assurances for Private Landowners* for additional details of this program.

The impacts associated with the dispersal of covered species onto neighboring lands are anticipated to be very limited and restricted to species that meet the criteria listed below.

- Species that are expected to increase in numbers on the Reserves.
- Species that are likely to spread onto neighboring lands as populations increase.
- Species for which there is a reasonable likelihood of take from routine, ongoing agricultural activities.

The Neighboring Landowner Assurances program will extend coverage only for three species: western pond turtle, California red-legged frog, and California tiger salamander.

Although California tiger salamander, California red-legged frog, and western pond turtle are capable of dispersing further than one mile, a one mile buffer was chosen to account for typical dispersal range of these species. Covered species are expected to disperse or move more than 1.0 mile but this radius accounts for the most likely area of effect into neighboring lands.

---

<sup>5</sup> See Chapter 2 for a definition of ongoing and routine agricultural activities.

Based on the landowner participation in other counties with approved HCPs that have similar programs (e.g., San Joaquin County), it is assumed that up to 10% of eligible lands will enter into neighboring land agreements, or no more than 2,040 acres. Of this, it is assumed that most of the potential impacts will occur on land cover types that support farming (agricultural and grassland land cover types) which are used by California tiger salamander, California red-legged frog, and western pond turtle for non-breeding or dispersal habitat, not as breeding or primary habitat. The estimated range of acres impacted represents between 0.1% and 0.6% of modeled habitat for the species covered in the Neighboring Landowner Assurances program.

Adverse effects from allowable agricultural activities on western pond turtle, California red-legged frog, and California tiger salamander could result from rodent control, active farming practices, vehicle and machinery travel, runoff from fields, or disturbance to adjacent streams or wetlands. The habitat for these three species is typically of low quality (and non-breeding), so the magnitude of impacts is expected to be low or very low.

Like Safe Harbor Agreements offered by USFWS, the Neighboring Landowner Assurances program does not allow take of species present before the Reserve was established; rather, coverage is restricted to species that disperse onto lands after the creation of the neighboring reserve. Take granted through the Neighboring Landowner Assurances program may slightly reduce the beneficial effects of the conservation strategy. The Neighboring Landowner Assurances program is described in detail in Chapter 10 *Assurances*.

## 4.4 Impact Assessment Methods

Implementation of covered activities will result in some incidental take of covered species. To meet regulatory requirements, to properly mitigate effects, and to distribute fees equitably, the amount of take must be discussed and, if possible, quantified. The allowable amount of take from permanent and temporary direct impacts is quantified by estimating impacts on land cover (methods for impact estimation are described below) (**Table 4-2** and **Table 4-3**, respectively). The total impacts by land cover type shown in these tables are the allowable impacts under the permits and the primary way in which impacts will be tracked during implementation to ensure permit compliance. Impacts to plant populations will also be tracked to ensure permit compliance, as described below under *Effects on Plant Occurrences*.

**Figure 2-6** and **Figure 2-7** show where many of the capital improvement projects proposed for coverage under this Plan are occurring. The amount of take is also described by estimating permanent and temporary direct impacts on modeled habitat for covered species (**Table 4-4**) and on plant occurrences (**Table 4-6**). If species habitat is not modeled, then land cover proxies are developed. The amount of take from indirect impacts is discussed qualitatively. A discussion of how the impact estimates were derived is provided below in Sections 4.4.1 *Direct Effects* and 4.4.2 *Indirect Effects*.

Because of the broad geographic and temporal scope of the Plan, the impact assessment has been conducted at a programmatic level. The impact numbers presented in this Plan are intended to reflect approximate losses and impacts rather than a precise quantification of impacts on land cover types. Total allowable impacts as described and quantified in the Plan (see **Tables 4-2, 4-3, 4-4, and 4-6**) represent the limit, or cap, on total impacts allowable under the Plan. Once these impact levels are reached, no further take is permitted pursuant to the Plan. Covered activities described in Chapter 2 do not have project-specific impact limits, although activities must be implemented consistent with the conditions described in Chapter 6. The Implementing Entity tracks impacts during Plan implementation to ensure that no covered activities are conducted beyond the capped impacts. As covered activities are implemented, specific impacts will be more accurately quantified. In general, project-specific impacts will be quantified in conjunction with the CEQA process and/or the development permit application process with a local jurisdiction (see Chapter 6). The goal of the impact analysis is to identify practical and appropriate impact assumptions to ensure the Local Partners full coverage for implementing covered activities throughout the permit term and to adequately fund the conservation strategy.

#### 4.4.1 Direct Effects

As described in Chapter 2, the covered activities are broad in scope and address the needs of all Local Partners. To quantify direct impacts on land cover types and streams, covered activities were grouped as they are in Chapter 2. These categories are Urban Development, In-Stream Capital Projects, In-Stream Operations and Maintenance, Rural Capital Projects, Rural Operations and Maintenance, Rural Development, and Conservation Strategy Implementation. Two additional categories—In-Stream Construction and Rural Construction—were added to address temporary, one-time impacts associated with construction of identified capital projects. In-Stream and Rural Construction impacts were identified for the area immediately adjacent (i.e., the area immediately surrounding the project area) to capital project footprints to account for the staging of project construction. As previously defined in Section 4.2 *Definitions*, temporary staging areas would result in temporary impacts to land cover; and will be returned to pre-project or ecologically improved conditions within the time allowed for temporary impacts. Major individual and collective projects or activities with the potential for significant impacts were identified for each category. Smaller-scale activities such as vegetation management and monitoring are captured in the analysis of operations and maintenance impacts. Covered activities that affect very small areas (less than 0.1 acres) were not individually assessed. These activities are still covered under this Plan; however, impacts related to these activities are assumed to be absorbed by the impact estimates developed for larger covered activities. Examples of such covered activities include off-trail monitoring and management activities conducted as part of the conservation strategy implementation.

In addition to grouping activities by the nine identified categories, impact mechanisms within each category were analyzed as either permanent or

temporary. While the impacts from covered activities have both permanent and temporary aspects (see Section 4.3 *Impact Mechanisms*), in most cases the associated impacts are largely either temporary or permanent. To facilitate the analysis and because parsing temporary and permanent impacts within categories would have a minimal effect on the results due to the programmatic nature of the analysis, only the dominant impact type is considered in each category.

Categories identified as having permanent impacts to land cover and species habitat are Urban Development, In-Stream Capital Projects, Rural Capital Projects, Rural Development, and Conservation Strategy Implementation. These categories were identified as permanent because they generally include the construction of structures that would result in permanent loss of the land cover on which they are built. Conservation Strategy Implementation falls into this category because of the permanent impacts associated with constructing new facilities such as fire/access roads, trails, visitor centers, and kiosks.

Categories identified as primarily<sup>6</sup> having temporary impacts to land cover and species habitat are In-Stream Operations and Maintenance, In-Stream Construction, Rural Operations and Maintenance, and Rural Construction. Operations and maintenance and construction impacts were considered temporary because operations and maintenance and construction activities were assumed to affect natural land cover types for a limited time and because these sites would return to pre-project or ecologically improved conditions within the time allowed for temporary impacts. Examples of temporary impacts include mowing and construction staging, which generally take place adjacent to a project footprint. Three exceptions to this grouping specifically called out in the Section 4.3, *Impact Mechanisms*, are SCVWD's Dam Maintenance Program, SCVWD's water supply operations and maintenance, and SCVWD's one-time vegetation management in lower Llagas Creek. Areas maintained under the Dam Maintenance Program and for water supply operations and maintenance (e.g., diversions structure and stream gage maintenance) will be maintained at such a level that the impacts will effectively result in a permanent loss of vegetation. Similarly, once vegetation in lower Llagas Creek is initially reduced, it will then be maintained under the Stream Maintenance Program. The initial reduction in vegetation is therefore more accurately a permanent reduction. Both of these covered activities are assessed as permanent impacts under the In-Stream Capital Project category.

Impacts on streams were identified in all impact categories as appropriate (i.e., for all projects that may have in-stream impacts). A permanent impact on a stream results from a loss of natural structure or function. Examples of activities resulting in permanent stream impacts include installing hardscape in the channel, culverting the channel, constructing a new bridge over the channel, or reducing channel complexity (e.g., removing riffle, runs, or pools). Examples of temporary stream impacts include dewatering, removal of in-stream vegetation so

---

<sup>6</sup> The assumption that operation and maintenance activities would result primarily in temporary effects was made for the purposes of estimating impacts for the Plan. The nature of impacts, whether temporary or permanent, will be determined on a project-level basis through the application process described in Chapter 6, where the frequency, duration, and nature of the impact will be documented.

that in-stream habitat is affected, and other actions that temporarily reduce stream function and habitat value.

Impacts to known occurrences of plants are assessed by plant occurrence and location. Methods and assumptions used for estimating impacts to covered plant species are described below.

## Baseline Land Cover

To estimate impacts resulting from implementation of covered activities over the course of the permit term, it was first necessary to identify the baseline conditions on which the impacts are assumed to occur (i.e., the anticipated composition and distribution of land cover at the time the Plan is implemented). Establishing a baseline helps to ensure that the amount of permanent impacts estimated in this Plan, particularly within the planning limits of urban growth where impacts are assessed by land use, are appropriately scaled (i.e., to ensure impact are not overestimated). Working with each of the cities and the County, parcels currently permitted for development or anticipated to be permitted by the time of Plan implementation<sup>7</sup> were excluded from the impact analysis and therefore considered part of the baseline conditions. Assumptions used to define the impact analysis baseline land cover are made only for the purpose of estimating an accurate level of take proposed for coverage under the Plan; these assumptions have no bearing on whether an activity may be covered or not. Project proponents for parcels assumed to already have permits may seek coverage under this Plan if the activity is covered, take coverage is available, and if the proponent follows the application requirements described in Chapter 6 (such coverage would be tracked and counted against allowable impacts).

Other parcels and sites were excluded from the impact analysis on the assumption that the existing land cover on these sites would not change substantially within the permit term or that the site was not zoned for urban development. Covered activities may still be implemented in these areas but these covered activities will not substantially change the land cover type (e.g., operations and maintenance activities). Areas excluded for the purposes of identifying baseline conditions are listed below.

- Parcels currently permitted for development or anticipated to be permitted by the time of Plan implementation<sup>8</sup>.
- Land use categories Rural Parks and Open Space, Urban Parks and Open Space, Agriculture, Ranchland/Woodland, and Water within the planning limits of urban growth (impacts are assumed to occur on these land uses outside the planning limit of urban growth).

<sup>7</sup> *Permitted* means a local land-use permit such as a building permit or grading permit. Some projects may not yet have endangered species permits, but they could not be covered by this Plan because they would obtain their local approvals before the Plan is completed.

<sup>8</sup> These parcels were only removed for the land cover impact analysis to ensure that land cover impacts were not over estimated. These parcels were not removed for the species and critical habitat analyses.

- Wastewater treatment ponds in Gilroy.
- The Norman Y. Mineta San José International Airport.
- The Reid Hillview Airport.
- State Parks lands.

## Effects on Land Cover and Streams

Various methods were used to quantify impacts on land cover and streams. An attempt was made to use a consistent approach; however, impacts of covered activities identified in *Urban Development*, *Rural Development*, and *Conservation Strategy Implementation* were calculated using a different method than most of the impact analyses. The sections below describe the methods utilized.

For all analyses, results were only considered to be impacts if the activity affected *natural* land cover types (i.e., land covers not already developed) or Agricultural and Developed natural community land cover types that may have some habitat value. Developed land cover types considered to hold some habitat value are Rural-residential, Golf courses/Urban parks, Barren, and Ornamental woodland. Non-assessed land cover types are the Agriculture developed/covered agriculture, Urban-suburban, Reservoir, and Landfill types.

### General Method

The analyses for In-Stream Capital Projects, In-Stream Operations and Maintenance, Rural Capital Projects, and Rural Operations and Maintenance were conducted in the same general manner. Wherever possible, the impacts of specific covered activities on land cover were modeled using GIS software. The general approach was to utilize a GIS overlay of project footprints or infrastructure on the mapped land cover and assess affected acres. To assess construction and operations and maintenance impacts, buffers were applied to GIS-mapped infrastructure or projects. The assumption is that some amount of surrounding acreage would be the target area for operations and maintenance and construction activities, such as vegetation management and staging, respectively. The same approach was used to assess miles of stream affected by covered activities.

Where GIS data were not available, assumptions were developed to describe the activity and estimate impacts. This process generally entailed describing the acres of impact likely to result from a specific activity, then distributing the acres of impacts across the land cover types likely to be affected by the activity. For example, to conduct the bridge construction/reconstruction analysis, existing bridge length and width information was used to quantify the amount of existing bridge that would need to be replaced within the permit term. An assumption for the amount of bridge expansion that would be required based on changing safety standards was also applied. Impacts of bridge construction were assumed to

affect only the riparian corridor and associated stream. Accordingly, the acres of impact were assigned proportionally to the riparian land cover types within the jurisdiction in which the activity was occurring (e.g., bridge reconstruction impacts in San José were assumed to affect riparian land cover types in proportion to the percent of riparian land cover types in San José).

To identify miles of stream impacts where GIS data were not available, assumptions were developed on the basis of the activity or project description, known or approximated number of stream crossings, and assumptions on crossing width. For example, stream impacts for most bridge projects were estimated based on total number of replaced bridges multiplied by an average assumed bridge width.

Overall, 30% of all estimated permanent impacts were calculated outside of GIS. Of this 30%, 57% of the estimated impacts are attributed to rural development. Approximately 25% of total estimated permanent stream impacts were calculated outside of GIS. For temporary impacts, approximately 41% of all estimated impacts were calculated outside of GIS. Approximately 5% of estimated temporary stream impacts were calculated outside of GIS.

**Tables 4-5a through 4-5f** provide a summary of the methods and key assumptions used to conduct the impact analysis. These tables are not intended to be exhaustively inclusive of all covered activities. Rather, these tables show how impacts were calculated for covered activities that have impacts significant enough to be estimated. Minor activities described in Chapter 2 are covered under this Plan even though they may not appear in these tables. Impacts of these minor activities are assumed to be addressed sufficiently by the approach taken in the impact analysis. Although these tables quantify impacts by project and by each Permittee, this was done for estimation purposes only. Compliance with this Plan will not be measured according to the estimated impacts for each project or Permittee, but rather by total land cover/habitat type impacted by the covered activities as a whole.

## Method for Urban Development

The analysis for urban development did not attempt to discern the impact of individual, separate activities, but rather assumed that all areas within the planning limits of urban growth for the three cities with current land use designations of urban development or rural residential development (as identified in **Figure 2-2, Land Use Categories**) would be fully affected (i.e., converted to a developed land cover). This assumption does not preclude covered activities from occurring on land uses for urban parks, agricultural, or woodland and rangeland; however, it is assumed that the majority of impacts inside the planning limits of urban growth will occur in areas with urban development land uses. This method also assumes that land uses inside planning limits of urban growth will remain approximately the same over the course of the permit term. As is shown in **Figure 2-2**, the majority of current land use is already urban development with some rural development. This approach will likely result in an overestimate of impacts because some of the Biological Goals and Objectives for

plants include commitments to preserve existing populations (e.g., Coyote ceanothus, Metcalf jewelflower) that are located within the San José, Morgan Hill, or Gilroy planning limits of urban growth. There are two exceptions to the assumption that all current land use designations of urban development or rural residential development will be fully affected. First, in-stream areas (Plan-identified streams, including channel bed and banks, and any adjacent riparian land cover types) were excluded from the Urban Development impact analysis and were assessed under In-Stream Capital Projects or In-Stream Operations and Maintenance on a project-by-project basis. Second, impacts occurring in the City of San José Coyote Valley Urban Reserve and the South Almaden Valley Urban Reserve; the City of Morgan Hill Southeast Quadrant; and the City of Gilroy Hecker Pass Specific Plan are assumed to be developed consistent with rural development. Impacts associated with urban development and its effects on watershed health and hydrology were assessed through an impervious surface analysis. This analysis is discussed in Section 4.4.2 *Indirect Effects*.

## Method for Rural Development

The method for calculating impacts of rural development was different than that used for other impact categories because the location and amount of rural development is difficult to predict. In addition, parcel sizes of rural development are highly variable, and the impacts of a single home are often not limited to the footprint of the home and access road. The analysis for rural development was based on the following key assumptions.

- Impact footprints of rural development in the future will be approximately one-third smaller than the footprints evident from aerial photo analysis conducted in 2007.
- The pace of rural development during the permit term will continue at approximately half of the average pace evidenced between 1995 and 2004.
- Rural development could occur anywhere in County jurisdiction consistent with County General Plan and zoning restrictions.

To refine the analysis, County planning staff identified development zones where rural residential development is expected to occur within the permit term. Six zones were identified on the basis of similar development patterns, parcel sizes, topography, and other landscape characteristics (**Figure 4-1**). Rural development was estimated for all areas in unincorporated Santa Clara County in the permit area outside open space (Type 1, 2, or 3) and excluding parcels within the planning limits of urban growth, unbuilt parcels approved for development, the South County Airport, reservoirs, SCVWD percolation ponds, and landfills.

## Amount of Rural Development

The estimated annual rate of new home construction in rural areas was based on the average number of residential development permits issued by the County within each development zone from 1995 to 2004 (10 years). The average of 40 permits per year was then applied throughout the permit term for a total of 2,000 permits granted over the 50-year permit term. This amount was then

adjusted downward by just over 50% to account for changing patterns in rural development and the coverage areas on the valley floor (see **Figure 2-5**). In addition, permits were assumed to be distributed throughout each of the development zones, with a greater proportion of the permits assumed to be granted in the valley floor areas. County planning staff verified that each development zone had the capacity to support the projected development. This assessment was based on the number of vacant parcels (parcels with no existing buildings as of the 2005–2006 Assessor’s roll) and slope (parcels with greater than 50% slopes were excluded). Where capacity did not exist in a zone, excess development was reallocated to other likely zones.

The estimate of permits for nonresidential construction sites (e.g., greenhouses, agricultural structures, telecommunication towers, rural commercial development) was based on the average number of permits issued from 1995 to 2006 (12 years). This average of 7.5 permits per year was applied to the 50-year permit term and then also adjusted downward.

In addition, six specific rural development projects (three County projects, two landfill expansion projects, and one quarry expansion project) were delineated in GIS and impacts calculated based on an overlay with the land cover layer. Impacts were aggregated with other Rural Development impacts. (The Kirby Canyon landfill project is considered a rural capital project, not rural development, so impacts were not included in this category.)

### **Footprint of Rural Development**

To translate the number of home sites predicted during the permit term to an estimate of land cover and species impacts, an average footprint of homesites was developed through air photo interpretation. The actual footprint of each homesite was digitized on screen in ArcView on the basis of substantial disturbances visible on the same color orthophotos used to map land cover (see Chapter 3). The landscape features listed below, when occurring as part of a homesite, were considered part of the direct impact footprint of rural development because they contained little or no habitat value for covered or other native species.

- Homes.
- Outbuildings.
- Driveways and parking areas.
- Landscaping and other active outdoor use areas such as lawns.
- Recreational vehicle trails.
- Vineyards or orchards.
- Heavily grazed or disturbed areas with bare soil.
- Barns, stables and corrals.
- Dirt roads.

The final impact footprint of each homesite was identified as all contiguous features listed above, plus a 50-foot buffer. This buffer incorporates a space around the area of direct impacts most likely to be affected by general maintenance and use of the space around homes such as landscaping, gardens, livestock enclosures, small outhouse structures, and defensible space as required by state fire codes. This area around the home is also subject to indirect impacts such as light, noise, and runoff.

To refine the methodology, several groups of test parcels were selected in the Santa Cruz Mountains and the Diablo Range and visited in the field. Once it was determined, based on field testing, that methods were being applied consistently, 1,199 parcels within the available developable area were randomly selected for the sampling (28% of all available parcels). The parcels were stratified between each side of the Santa Clara Valley and the valley floor to ensure a geographically representative sample. Of these, 693 parcels had no visible home sites so were discarded. The final sample consisted of 506 parcels that were digitized. Final parcel sizes and locations varied widely in the study area, consistent with actual patterns.

Based on this random sample, the median impact footprint<sup>9</sup> of rural home sites was 2.6 acres in the valley floor and Almaden zones and 3.3 acres in the near hills and remote hills zones (**Figure 4-1**). These impact footprints were adjusted downward to 2 acres per development permit to account for changing development patterns (R. Eastwood pers. comm.). The average impact footprint for nonresidential development was estimated to be 1.9 acres.

This approach does not account for the impacts of rural development on landscape linkages or wildlife connectivity. Some larger rural development projects may degrade landscape linkages or impede wildlife movement. Because of the uncertain location of these large rural development projects, their specific effects on wildlife connectivity cannot be evaluated at this time. However, the Plan has incorporated mechanisms to evaluate these effects during implementation and ensure that the conservation goals and objectives of this Plan related to landscape linkage and wildlife connectivity are still met. They will be met through land acquisition of key landscape linkages before development occurs (see Chapter 5, Section 5.3.1 *Land Acquisition and Restoration Actions*), or through project redesign (see Chapter 6, Section 6.4.4, subheading *Condition 7 Rural Development Design and Construction Requirements*).

### Calculating the Impacts of Rural Development

To estimate the impact of rural development on land cover, the total number of expected housing units and commercial development sites over the permit term within each development zone was multiplied by the median impact footprint within each zone. These impacts were then distributed across all land cover types determined to be available for development in proportion to the occurrence

<sup>9</sup> The median value was chosen as the best measure of central tendency of the data because of the strong influence of a few data points with very large footprint estimates. This approach was used for the impact analysis estimate only. Fees on rural residential development will be assessed the fee based on their actual project footprint, as defined in Chapter 9.

of each land cover type within each development zone. Land cover types determined to be available for impact are all those land cover types in the permit area except the cases listed below.

- Parcels excluded from the baseline conditions described above.
- Parcels within the planning limits of urban growth.
- The South County Airport<sup>10</sup>.
- Open space types 1, 2, and 3.
- SCVWD groundwater recharge ponds.
- Reservoirs.
- Landfills.
- Areas within the stream setback zone described in Chapter 6 (note that stream and associated riparian land cover impacts were calculated separately from the land cover analysis and are discussed below).

This distribution included urban-suburban, landfill<sup>11</sup>, reservoir and developed agriculture land cover types (the four land cover types determined to have no habitat value and for which no fee is required [see Chapter 9]) as it is assumed that some new rural development will occur in these land cover types. This method may over- or underestimate effects on some land cover types (e.g., chaparral is more abundant on steep slopes where rural development is less likely to occur). However, a simpler approach was preferred over a complex model with many more assumptions due to the programmatic nature of this impact analysis. Acres of impact for each land cover type were then summed across each development zone to determine total impacts. In addition to the impacts calculated using this method, the County is requesting an additional 78 acres of impact allowance for development of new or expansion of existing County facilities (e.g., Mariposa Lodge, James and Holden Ranches, and Muriel Wright Center).

To estimate miles of stream affected by rural development it is assumed that one out of every 10 residential developments permitted would result in an average of 20 feet of linear stream impacts, primarily from construction of an access road (R. Eastwood pers. comm.). To estimate acres of riparian vegetation affected by rural development it is assumed that each creek crossing (one per 10 residential developments) is 40 feet wide (outer edge of riparian corridor to outer edge of riparian corridor) and that the entire area under the crossing represents a permanent loss of riparian vegetation. Multiplying 20 feet (linear feet of stream affected per crossing) by 40 feet by one-tenth the number of anticipated rural residential developments and converting to acres yields a maximum impact estimate for permanent impacts on riparian land cover types due to rural

<sup>10</sup> While rural development (e.g., construction of homes) is not expected to occur on airport lands, the airport expansion is a covered activity. These impacts were estimated using a site-specific approach informed by the airport's master plan.

<sup>11</sup> Note that Kirby Canyon Landfill fill areas 1, 2, and 5 were exempted from the baseline data; accordingly, impacts from rural development would not be distributed to this area.

development. Note that total riparian land cover impacts may be higher if riparian land cover types occur outside the stream setback area and impacts are identified through the land cover analysis described above. While this analysis captures direct impacts to streams, it does not address indirect impacts such as degradation of water quality due to increased development. These types of impacts are assessed through the impervious surface analysis discussed below in Section 4.4.2 *Indirect Effects*. Rural development will be subject to the conditions identified in Chapter 6, including keeping crossings to the minimum amount required per development and avoiding riparian vegetation whenever possible.

### **Method for Rural Development within the Planning Limits of Urban Growth**

The City of San José anticipates some development will occur inside the city limits but outside the planning limit of urban growth. In addition, the Coyote Valley and South Almaden Valley Urban Reserves were removed from the urban development impact analysis, as were Morgan Hill's Southeast Quadrant and the Gilroy's Hecker Pass Specific Plan. For the purposes of the impact analysis, the City of San José assumes three sites will be permitted each year of Plan implementation (A. Danielsen pers. comm.) in areas inside city limits but outside the planning limit of urban growth, and not including the urban reserves. The Coyote Valley and South Almaden Valley urban reserves are assumed to be developed at rates consistent with the rural development impact analysis for the County in the valley floor rural development zone. This development may occur in the Near East Hills, Near West Hills, Valley Floor, and Almaden Valley rural development zones. Average size of development identified for these areas (2 acres) as part of the rural development analysis was utilized for this analysis as well. Total acres of estimated impacts were calculated and distributed proportionately across land cover types inside the San José city limits but outside of the planning limit of urban growth, but excluding the following lands.

- Parcels excluded from the baseline conditions of the Plan.
- Open space types 1, 2, and 3.
- SCVWD groundwater recharge ponds.
- Reservoirs.
- Landfills.
- Areas within the stream setback zone described in Chapter 6 (note that stream and associated riparian land cover impacts were calculated separately from the land cover analysis and are discussed below).

Stream impacts were calculated using the same method as rural development in the county described above.

## Method for Conservation Strategy Implementation

The analysis for Conservation Strategy Implementation was based on those activities expected to occur in the Reserve System as identified in Chapter 2, Chapter 5, and Chapter 9. Estimates were informed by current land management activities of agencies such as the Santa Clara County Open Space Authority that are assumed to be similar to the land management practices that will be applied to the Reserve System. Once an estimate of acres of impacts was developed, the impacts were distributed across the land cover types most likely to be affected by these actions. Capital projects in the Reserve System were assumed to have both permanent and temporary impacts. Temporary impacts were associated with construction activities. With the exception of utility line maintenance in the Reserve System, no additional impacts were assessed for operations and maintenance activities as it is assumed these impacts are very small. See **Tables 4-5g and 4-5h** for the methods and assumptions used for this impact analysis.

No permanent or temporary impacts are identified for conservation actions either because these activities are assumed to have a net benefit on all covered species (see Chapter 5 *Conservation Strategy*) or because these activities result in impacts that are too small to quantify. Grasslands converted to other land cover types as a result of restoration or creation actions will not be counted as an impact. In addition, the grassland removed will not be counted toward the overall preservation goals for grasslands.

## Method for Three Creeks HCP

The draft Three Creek HCP (April 2009) provides an impact analysis of all activities covered under that plan. This Plan integrated the impact analysis methods, data, and/or impact numbers developed for the draft Three Creeks HCP to ensure consistency of impact evaluation between the two Plans.

## Impact Caps on Serpentine Bunchgrass and Wetlands

Three land cover types (serpentine bunchgrass grassland, coastal and valley freshwater marsh, and seasonal wetland) have impact caps that were informed by the impact analysis, but that were set lower than what was estimated by the impact analysis. The reduction in impacts is intended to account for avoidance and minimization that is required by the conditions on covered activities and because the Plan's fee structure provides financial incentive to avoid these land cover types. Setting impact caps on these land cover types ensures that impacts are not over-estimated and that the conservation strategy is developed consistent with the impacts actually expected to occur.

## Effects on Covered Species Habitat

For covered species with modeled habitat, impacts were assessed based on the intersection of covered activities and covered species modeled habitat. This method uses habitat models that identify the location and amount of habitat assumed to be suitable for each species (see **Tables 3-5 and 3-6** and species model descriptions in **Appendix D**). Estimates of incidental take are based on the habitat models developed for 16 of the 19 covered species. As described in Chapter 3, these estimates of suitable habitat are likely to be somewhat inflated (i.e., conservative) because (1) habitat models may overestimate the actual extent of suitable habitat, and (2) not all suitable habitat is occupied by the subject species. Therefore, species habitat is used as a proxy for species occurrence because of the limitations of survey data. Impacts to Bay checkerspot butterfly were capped lower than estimated impacts to account for avoidance of modeled habitat that may be possible for projects where siting is flexible (e.g., rural development).

For covered plants, impacts were also assessed at the occurrence level (assumed to be equivalent to populations; discussed in the above section) because of the stability of plant occurrence locations (i.e., plants move very slowly). For three plant species, sufficient information was not available to create habitat models. In these cases, worst-case assumptions were used regarding the amount of suitable habitat removed by covered activities. Both methods are described in more detail below.

## Effects on Habitat of Modeled Species and Critical Habitat

For the 16 species with habitat distribution models, maximum allowable temporary and permanent impacts on modeled habitat acreages as shown in the models were identified (**Table 4-4**). Critical habitat is designated for three of the covered species (Bay checkerspot butterfly, California tiger salamander, and California red-legged frog) (**Figures 4-4 through 4-6**). Maximum total allowable impacts in critical habitat for these three species are provided in **Table 4-9**. For covered activities with a GIS overlay, the impact analysis was conducted by intersecting the GIS overlay with the modeled habitat of each species (**Appendix D**). For covered activities without GIS data, the following steps were used to identify impacts.

- **Step 1:** GIS was used to identify the acres of habitat for each modeled species and for critical habitat within each of the County-defined development zones (**Figure 4-1**). These zones were used in the Rural Development impact analysis. Rural Development constitutes a large proportion of the non-GIS covered activities, and the zones identified for rural development activities also reflect the general location of many other covered activities not tied to exact locations.
- **Step 2:** Acres of impacts for non-GIS covered activities were estimated within each development zone for each covered activity assessed (see **Table 4-5a through 4-5h**) by applying a weight factor that would result in a

higher or lower percentage of covered activities being attributed to one zone or another. For example, it is expected that most of the impacts associated with implementation of the conservation strategy will occur in the remote east hills and so a higher percentage of estimated impacts for those activities are attributed to the remote east zone than to the valley floor zone. Impacts were estimated by zone according to the general location of the activities.

- **Step 3:** Impacts by development zone were assumed to affect each species in proportion to the amount of the modeled habitat for that species found in that zone.

GIS was used to calculate approximately 63% of species-specific permanent impacts and approximately 60% of species-specific temporary impacts. GIS was used to calculate approximately 32% of critical habitat permanent impacts and approximately 74% of critical habitat temporary impacts. The remainder of the species and critical habitat impacts were developed based on assumptions non-GIS calculated impact distribution and habitat or critical habitat distribution.

## Effects on Habitat of Non-Modeled Species

### Plants without Models

Habitat models could not be developed for Tiburon paintbrush, Coyote ceanothus, and Santa Clara Valley dudleya because the microhabitat requirements of these species occur at a finer scale than the Plan mapping. For example, Santa Clara Valley dudleya occurs on serpentine rock outcrops, which often occur as scattered patches that are only several square feet in size. In addition, there are few known occurrences of most of these species in the study area (**Table 4-6**), except for Santa Clara Valley dudleya, making the model verification more difficult.

In the absence of models, estimates of temporary and permanent impacts to these species were based on impacts to the number of known occurrences that could be impacted by covered activities, as described above (**Table 4-6**). As a general guide and “worst-case” analysis of potential habitat, effects are also cited to land cover types that are broadly associated with each of these plant species.

## Effects on Plant Occurrences

In addition to the impacts to covered plant species habitat described above, it was important to examine as accurately as possible impacts to individual plant occurrences. The potential impacts to plant occurrences from covered activities, and the total allowed impacts to each species were determined by the following methods.

Potential direct effects on plant occurrences were analyzed based on occurrence data in the California Natural Diversity Database (CNDDB), records from SCVWD’s Biodiversity Monitoring Program, and data collected on the United Technologies Corporation property (T. Marker pers. comm.). Impacts were

assessed for covered activities for which GIS data were available. Covered activities with significant impacts (i.e., over 100 acres) for which specific location data are not known include rural development, County Parks capital improvement projects, and dam seismic safety retrofit borrow sites. In addition to the methods described here, impacts to specific plant occurrences from the SCVWD Dam Maintenance Program were provided by SCVWD. These were determined by site surveys during their EIR preparation and detailed analysis of the footprint of dam maintenance activities.

It is important to make a distinction between impacts that reduce the long-term viability of an occurrence and impacts that do not reduce the long-term viability of an occurrence. This analysis assumed that in most cases, occurrences that overlapped with the footprint of covered activities would result in complete loss of the occurrence. However, there will be some temporary or partial impacts to occurrences where the occurrence may recover in subsequent years and long-term viability is not affected. This possibility is discussed in Chapter 4, Section 4.4.1, subheading *Partial Permanent Impacts to Plant Occurrences* below and Condition 20 (Chapter 6). The “potential impacts” and “impact limits” defined and discussed in this section refer in all cases to the reduction of long-term viability of a covered plant occurrence.

For the purposes of this Plan, an occurrence of an annual plant species will be assumed to retain long-term viability and will not require replacement in the Reserve System if the decline in population size and percent cover from pre-project conditions is less than 25% over a monitoring period of at least 5 years (i.e., cumulative change over 5 years), unless site-specific conditions otherwise suggest substantial declines in population viability. The population size of annual covered plants may fluctuate more than 25% annually due to environmental variation such as rainfall. If extreme or unusual climate conditions affect the species, then monitoring will be extended 1 or 2 years, as appropriate to assess impacts and success (see Condition 20, Chapter 6).

An occurrence of a perennial plant species will be assumed to retain long-term viability and will not require replacement in the Reserve System if the decline in seedling recruitment and density from pre-project conditions is less than 25% over a monitoring period of at least 3 years, unless site-specific conditions otherwise suggest substantial declines in population viability (see description of Condition 20 in Chapter 6).

Specifically, potential impacts were assessed by first creating a GIS overlay of the location of covered activities (i.e., the planning limit of urban growth and covered capital projects illustrated in **Figure 2-6** and **Figure 2-7**) with the plant occurrence data for all covered plant species. Next, this data and CNDDDB occurrence data, were used to determine which occurrences of each species would be impacted by each activity. Finally, total potential impact numbers were determined. The results of this analysis are summarized in **Table 4-6** and discussed for each species in more detail later in this chapter. The impact limits in this table will be tracked during implementation to ensure permit compliance.

After the total potential impacts were calculated, actual impact limits were determined for each species. The impact limit was determined based on a number of factors, including (but not limited to) the overall species range and distribution, number of known occurrences, recent frequency with which new populations have been discovered, and rarity status.

In this section, impacts are discussed in terms of numbers and percentages of occurrences as well as estimates of absolute numbers of individuals where such estimates are feasible (impacts on modeled habitat is discussed in Section 4.6.8 *Serpentine Plants* and 4.6.9 *Non-Serpentine Plants* below). For annual plant species, discussion of absolute numbers is difficult as the populations can fluctuate widely from year to year due to environmental variation (e.g., rainfall). Some occurrences in the CNDDDB include estimates of numbers of individuals, however, many occurrences do not or the estimates are from only one year. Additionally, in the rare cases where there are multiple years' data, these numbers often vary widely (e.g., from hundreds in one year to thousands in another for just one occurrence).

As shown in **Table 4-6**, the Plan does not allow for the reduction of long-term viability of Tiburon Indian paintbrush and Coyote ceanothus. For more details on these impacts, including a discussion of permanent and temporary impacts to modeled habitat, see the discussion on each species later in this chapter.

It is expected that new occurrences of many of the covered plants will be discovered both within the impact areas and the Reserve System. In many cases, it is warranted to allow additional impacts to covered plants beyond the occurrences known at this time. Limits on take of some covered plant species can be increased up to the limit shown in the final column of **Table 4-6**. **Table 5-16** identifies the total number of occurrences in the study area<sup>12</sup> and the number of new occurrences that must be protected in the Reserve System before these additional impacts can occur. The species selected for additional limits and the limits set were determined based on two criteria.

- Future survey efforts in the permit area are likely to reveal that there are more occurrences of the species than are currently known.
- There are more occurrences known in the study area at the time of permit issuance than the Recovery Plan de-listing criteria or, for non-listed species, more than the long-term conservation criteria (U.S. Fish and Wildlife Service 1998)<sup>13</sup>. For species without de-listing or long-term conservation criteria, there must be more than 20 occurrences throughout the species' range.

Based on these criteria, all covered plants except three qualify for an increase in allowable impacts during Plan implementation if additional occurrences are found and protected. No additional impacts to Coyote ceanothus, Tiburon Indian

<sup>12</sup> Plant occurrences in the expanded burrowing owl study area do not count toward the baseline necessary before additional impacts may occur.

<sup>13</sup> Santa Clara Valley dudleya de-listing criteria is 30 populations. Species with long-term conservation criteria are Mount Hamilton thistle (23 populations), smooth lessingia (10 populations), and most beautiful jewelflower (22 populations).

paintbrush, or Metcalf Canyon jewelflower are allowed under the Plan even if additional occurrences are found.

As with all other impacts to covered plant occurrences, new occurrences of the species must be protected in the Reserve System before the impacts occur and the protected occurrences must be in as good or better condition than the new occurrences impacted by covered activities (“condition” is defined in Chapter 5, Section 5.3.1 *Land Acquisition and Restoration Actions*). See Chapter 5 for protection requirements to allow additional take limits in **Table 4-6**. Created occurrences will not count toward this Stay-Ahead provision for plants due to the highly experimental nature of creation. For the purposes of this Plan, created plant occurrences will not be used to mitigate adverse effects but rather to contribute to the recovery. The only exception to this rule is Coyote ceanothus. Because it may not be possible to protect one occurrence of Coyote ceanothus in the timeline described in Section 5.4.11, a created occurrence may serve as a portion of the mitigation for this species (see Chapter 5, Section 5.4.11 *Coyote Ceanothus* for details).

## Partial Permanent Impacts to Plant Occurrences

Certain covered activities could have permanent impacts to a portion of plant occurrences through construction, occasional operations and maintenance, and other short-term activities. If impacts resulting from covered activities do not reduce the long-term viability of the plant occurrence as described in Chapter 6, Section 6.6.2, subheading *Condition 20 Avoid and Minimize Impacts to Covered Plant Occurrences*, then it will be considered a partial impact on the occurrence and will not count toward the impact limits in **Table 4-6**. If the impacts do result in reduction of long-term viability of the occurrence, then it would be considered a permanent impact, and the impacts to the occurrence would count toward the maximum number of impacts to that species allowed under the Plan. For the purposes of this Plan, an “impact” to a plant occurrence results from the removal of an occurrence or the reduction of long-term viability of an occurrence (as defined in Chapter 6, Section 6.6.2, subheading *Condition 20 Avoid and Minimize Impacts to Covered Plant Occurrences*). Conditions on covered activities minimize the effects of covered activities on covered plants, and include monitoring actions and success criteria to determine the effects on long-term viability (see Chapter 6, Section 6.6.2, subheadings *Conditions 19 Plant Salvage when Impacts are Unavoidable* and *Condition 20 Avoid and Minimize Impacts to Covered Plant Occurrences*).

### 4.4.2 Indirect Effects

Unlike direct impacts, which are estimated quantitatively, indirect impacts are assessed qualitatively except for nitrogen deposition and watershed impervious surfaces for which quantitative analyses were run. In most cases the indirect impacts on species are summarized in **Table 4-1** and discussed in narrative form in the results sections below. As discussed above, estimates of direct effects on

land cover types have been quantified conservatively (i.e., somewhat overestimated). These conservative estimates are intended, in part, to incorporate many of the indirect effects of the covered activities listed in **Table 4-1** and ensure that the conservation strategy provides enough conservation to offset these indirect impacts.

## Impervious Surfaces

Impervious surfaces are materials of natural or anthropogenic sources that prevent the infiltration of water into soil. Impervious surfaces can affect the flow, sedimentation load, and pollution composition of stormwater runoff. An increase in impervious surfaces on a landscape is directly related to increases in human activity through the development of structures and infrastructure such as buildings, streets, sidewalks, and parking lots.

Classification of watersheds and subwatersheds by the amount of impervious cover is an important component of developing land use and habitat planning goals. Although presence of riparian vegetation and wetlands can mitigate the impacts of impervious cover, a watershed with high impervious cover is generally not able to support a high-quality stream system. A strong negative relationship between biotic integrity, land use, and riparian conditions begins to occur at approximately 10% imperviousness. Stream degradation occurs at relatively low levels of imperviousness (10–20%) (Chester and Gibbons 1996).

According to the Center for Watershed Protection (2003), an initial guide to evaluating urban/suburban stream quality is: (1) sensitive streams (0–10% imperviousness) typically have good water quality, good habitat structure, and diverse biological communities if other stresses are absent; (2) impacted streams (10–25% imperviousness) show clear signs of degradation; (3) non-supporting streams (>25% imperviousness) have a highly unstable flow and poor biological condition.

The Plan includes an analysis of the expected increase in impervious surfaces due to urban development and other covered activities. This analysis provides an indication of the magnitude of change of impervious surfaces in the watershed and therefore how covered aquatic species and other native aquatic species might be affected.

For the purposes of the Plan, the important metric is the change in impermeability between existing conditions and conditions in the study area at the conclusion of Plan implementation. To assess this change, the quantity of impervious surface in each of the study area's major watersheds was calculated, both upstream and downstream of reservoirs, using the existing land cover classification developed for the Plan (**Figure 3-10**). An impervious surface assumption for each land cover was derived (**Table 4-7**) from the Center for Watershed Protection research (Cappiella and Brown 2001), based on impervious cover classifications from eight geographic locations in the United States. That group's research has shown that the amount of impervious cover on a developed parcel is generally very similar for a particular zoning category no matter where

it is located. The literature also notes there are no nationally applicable or standard coefficients that account for the variability in forest, shrub, and herbaceous cover and turf cover coefficients.

## Method for Calculating Impervious Surface

The calculation used for determining impervious surface cover is shown below.

$$ALC * IC = AIC$$

where:

**ALC** = acres of land cover

**IC** = impervious assumption for each land cover

**AIC** = impervious area in acres

This equation was first applied to existing land covers to calculate the current impervious surfaces (in acres) for each subwatershed (Coyote, Guadalupe, Llagas, Uvas, and Pacheco). **Figure 4-2** shows the watersheds assessed in this analysis. To account for interim projects (those projects entitled for development in advance of Plan implementation), it was assumed that interim projects located inside the planning limit of urban growth would be developed to the urban-suburban land cover type and that interim projects located outside the planning limit of urban growth would be developed to the equivalent of the rural-residential land cover. These assumptions are reflected in the existing conditions of the impervious surface analysis.

The results of the impact analysis described in Section 4.4.1 *Direct Effects* were used to identify the acres of each type of land cover anticipated to exist at the conclusion of Plan implementation. To do this, each covered activity analyzed for the impact analysis was assigned a new land cover type that is assumed to be present after covered activity implementation. The majority of impacts are associated with urban or rural residential development. For these two covered activities, all impacted areas inside of the planning limit of urban growth were assumed to become the Urban-Suburban land cover type, and all areas impacted by rural development were assumed to become the Rural Residential land cover type. Land cover type conversions were assigned to the remainder of covered activities based on the assumed land cover type present after covered activity implementation.

Next, covered activities were assigned to watersheds where they are assumed to be implemented. As described above, the impact analysis required both GIS analyses and use of assumptions to describe the activity and estimate impacts (see **Tables 4-5a through 4-5f** for details). For those activities mapped in GIS, location by watershed and land cover type assumed for post-implementation were calculated using GIS. For those activities where the exact location of the activity is not known in GIS, assumptions were developed to assign the activity to a watershed.

Once land cover types by watershed for post-covered activity implementation were established, the above equation was again applied to calculate the amount of impervious acres within each subwatershed. The results are shown in **Table 4-8**.

There are several other partial watersheds in the study area (i.e., Alameda, Calabazas, South Santa Clara Valley, San Thomas, Santa Cruz Mountains, and Watsonville watersheds) that were not included in this analysis. As a result, approximately 23,000 acres of the study area were excluded. In addition, because covered activities were either assessed in GIS or were distributed to watershed according to assumptions on where the covered activity would occur, not all impacts were assessed through this analysis as they either will or are assumed to occur in non-assessed watersheds. This may result in a small underestimation of changes in study area imperviousness.

## Nitrogen Deposition

Indirect impacts of increased nitrogen deposition on natural communities and covered species are anticipated to result from urban development and rural development covered under the Plan. These covered activities would result in increased air pollutant emissions from passenger and commercial vehicles and other industrial and nonindustrial sources. Emissions from these sources are known to increase airborne nitrogen, of which a certain amount is converted into forms that can fall to earth as depositional nitrogen. It has been shown that increased nitrogen in serpentine soils can favor the growth of nonnative annual grasses over native serpentine species (Weiss 1999). These nonnative species, if left unmanaged, can overtake the native serpentine species, including dwarf plantain (*Plantago erecta*), the host plant for larval Bay checkerspot butterfly. Nonnative plants may also compete with native plants for water, nutrients, light, and sites for germination, crowding out covered plants (e.g., Metcalf Canyon jewelflower, most beautiful jewelflower, and fragrant fritillary). California grasslands are believed to be among the most sensitive to nitrogen deposition (Fenn et al. 2010). Coyote ceanothus may also be affected by competition with nonnative species, but because this covered species is a woody plant, the effects of such competition are likely to be less severe than the effects on native herbaceous species. To assess the degree to which nitrogen deposition will increase as a result of Plan implementation, a nitrogen deposition study was conducted (see **Appendix E**).

## Summary of Methods

Nitrogen deposition was analyzed using several modeling approaches in order to estimate the sources that contribute to deposition in the study area. In order to estimate contributions from individual roadways and to assess the increase in deposition due to increases in traffic, Gaussian models for a limited domain were applied to receptors centered on serpentine habitat that supports populations of the threatened Bay checkerspot butterfly. Modeling with Gaussian models, while

not providing an estimate of overall deposition, provides an estimate of deposition from individual roadways and the expected increases in deposition from those roadways in the future. The much more complex Community Multiscale Air Quality modeling system (CMAQ) was also used to simulate the study area's more complex nitrogen transport processes, and, using the Particle and Precursor Tagging Methodology source apportionment technique, to estimate contributors to deposition on a broader scale. Modeling with CMAQ also provides estimates of expected increases in deposition in future years.

## 4.5 Effects on Natural Communities/Land Cover

### 4.5.1 Direct Effects

Temporary and permanent impacts of each covered activity on each land cover type are summarized in **Tables 4-2 and 4-3**.

In most cases the data provided and assumptions made were reasonable worst-case assumptions of future project impacts. The actual impacts of specific projects over the permit term of 50 years may vary from the assumptions described in **Tables 4-5a–h** and total impacts will likely be less than the maximum allowable impacts in **Tables 4-2 and 4-3**.

In-stream impacts calculated for projects without exact footprints distribute all impacts across riparian land covers in proportion to the land cover type's occurrence in the study area. This approach may overestimate actual impacts because riparian land cover may not be present everywhere a project is conducted, particularly in urban areas. Moreover, actual in-stream impacts may be somewhat lower than those calculated because of flexibility in implementing avoidance measures (e.g., building clear-span bridges to avoid streams, building in sites where no riparian vegetation exists).

Stream impacts may be overestimated because miles of impact were calculated on the basis of project footprints. Some capital projects, such as flood-control projects that do not include concrete or riprap, will be able to avoid or minimize impacts on streams.

Estimated impacts on rare or sensitive land cover types do not account for project-by-project avoidance that will be applied to comply with the conditions detailed in Chapter 6 or other regulations such as CEQA. For example, recreational facilities such as buildings, outhouses, trails, and trailhead facilities, can usually be sited away from sensitive land covers. Consequently, impacts on serpentine grassland, serpentine chaparral, valley oak woodland, and knobcone pine woodland may be overestimated. While the areal extent of the impact footprint of these projects may not change, judicious siting may reduce the impacts on sensitive land cover types.

## 4.5.2 Indirect Effects

### Impervious Surfaces Analysis Conclusions

The results are shown in **Table 4-8**. Through comparison of existing and future watershed imperviousness, it is possible to estimate the level of impact on watershed health that implementation of covered activities may have on each subwatershed, as measured by imperviousness.

This imperviousness analysis does not take into account any stormwater management activities that would decrease run-off in the study area (e.g., cisterns or retention ponds). These types of requirements are currently integrated into the San Francisco Bay Regional Board NPDES permits and will be incorporated into new Central Coast Regional Board NPDES permits in the future. As such, this analysis may overestimate the increase in run-off into local streams that may degrade water quality. See Chapter 6, Section 6.4.1, subheading *Condition 3 Maintain Hydrologic Conditions and Protect Water Quality* for more details on stormwater management in the study area.

### Nitrogen Deposition Analysis Conclusions

Indirect impacts of continued nitrogen deposition on natural communities are anticipated to result from urban development and rural development covered under the Plan. Serpentine land cover types are the focus of preservation and enhancement actions to offset the effects of nitrogen deposition (among other impacts). However, several other land cover types in the study area have been identified as sensitive or potentially sensitive to nitrogen deposition (Weiss 2006): Northern mixed and serpentine chaparral, mixed oak woodland, foothill pine-oak woodland, mixed evergreen forest, and redwood forest are known to be sensitive to nitrogen deposition. According to this report, California annual grassland, valley oak woodland, blue oak woodland, coast live oak forest and woodland, freshwater marsh, seasonal wetland, and pond may be sensitive to nitrogen deposition.

### Baseline Deposition

Emissions for the base year Gaussian modeling were based on traffic counts for highways and roads in 2005. For CMAQ modeling, base year emissions were acquired from the Bay Area Air Quality Management District (BAAQMD). Estimates of baseline deposition based on observations of nitrogen dioxide (NO<sub>2</sub>) concentration and modeling using CMAQ both give estimates of total nitrogen deposition of about 6 kg-N/ha/y, which is consistent with other studies such as Weiss (2006).

## Changes in Nitrogen Deposition during the Permit Term

Reliable future year emissions were not available when the CMAQ modeling was conducted. As such, future year emissions were extrapolated from the base year based on population growth. Using this assumption, contribution of mobile source emissions in the habitat area are estimated to increase by about 0.6 kg-N/ha/y in 2035 over the base year and by another 0.5 kg-N/ha/y in 2060. The San José contribution to nitrogen deposition in the habitat areas is estimated to be 38% in 2035. Gaussian modeling of major roadways near the habitats indicates an increase in nitrogen deposition of about 0.25 kg-N/ha/y in 2030 over the base year (a 4% increase in total deposition). The increase in 2060 relative to 2030 could be from 0.4 kg-N/ha/y to more than 1 kg-N/ha/y (at the Hale Avenue site) depending on location (a 7% to 17% increase in total deposition).

Based on the CMAQ modeling, should increases in NO<sub>x</sub> emissions occur in proportion to growth within the study area, within Santa Clara, and within the region, total average nitrogen deposition in the area around and including the habitat areas could increase to 8 kg-N/ha/y in 2035 (a 33% increase) and almost 10 kg-N/ha/y in 2060 (a 66% increase). Gaussian modeling indicates that, when emissions are extrapolated based on projected growth, contributions to nitrogen deposition from major roadways could increase by almost a factor of two by 2030 and by an even larger amount by 2060.

As described above, the modeling shows that increases in NO<sub>x</sub> emissions result in increased nitrogen deposition. As such, it may be fair to assume a similar correlation between a reduction in NO<sub>x</sub> emissions and a reduction in nitrogen deposition. In 2011 the BAAQMD released future year projections through 2025. These projections show a decrease in NO<sub>x</sub> emissions from approximately 449 tons/day in 2008 to 360 tons/day in 2025 (a reduction of 89 tons/day). There appears to be a slight increase in NO<sub>x</sub> emissions between years 2022 and 2025. These new projections indicate that the future year nitrogen deposition rates extrapolated in this analysis are over-estimated and suggest that there may be a decrease in current rates of nitrogen deposition. However, NO<sub>x</sub> emissions, and therefore nitrogen deposition, are not expected to cease entirely. In addition, emissions containing other nitrogen compounds (e.g., NH<sub>3</sub> [ammonia]) may also contribute to nitrogen deposition. As cited in Fenn et al. (2010), a recent study shows that 25% of the nitrogen emissions from light duty vehicles in three California cities are in the form of NH<sub>3</sub>, and in newer cars the proportion is greater (Bishop et al. 2010 as cited in Fenn et al. 2010). The BAAQMD (2010) reports 52 tons/day of ammonia emissions in the Bay Area as of 2008. Leading sources of ammonia emissions include landfills, wastewater treatment, and refineries (19.8%); light-duty motor vehicles (17.4%); livestock (15.5%); commercial refrigeration (wineries, breweries, and cold storage warehouses; 15.4%); human respiration and perspiration (13.8%); and domestic animal waste (9.0%).

Fenn et al. (2010) report a critical load (the load at which undesirable effects are observed) for California serpentine grasslands of 6 kg-N/ha/y. This load is equal to the current estimates for nitrogen deposition rates in the study area (see *Baseline Deposition* above). While this rate may be expected to drop based on

the BAAQMD report of reduced NO<sub>x</sub> emissions, it is uncertain how the reduction will be offset by increases in other nitrogen sources, or what level of reduction would be required to reverse the current adverse effects of nitrogen deposition. Additionally, studies from grasslands in other regions of North America have shown that significant impacts to biodiversity in grassland communities can occur from the accumulation of even low levels of nitrogen deposition (Fenn et al. 2010).

## Contributors to Deposition

The amount that various sources contribute to deposition was assessed with different modeling approaches. The most complete of these methods was the use of the PPTM tagging approach in CMAQ. In the base year, the CMAQ PPTM simulation attributes 30% of the total nitrogen deposition to mobile sources within the study area. Another 16% of the nitrogen deposition comes from stationary sources in the study area. Therefore, 46% of nitrogen deposition on the habitat areas comes from existing development and vehicle traffic generated locally within the study area. The remainder of Santa Clara County contributes 17% of the nitrogen deposition while the remaining Bay Area counties account for about 11% of the deposition. The CMAQ simulation indicates that the remaining 26% of the N-deposition comes from anthropogenic emissions in the remainder of the modeling domain (i.e., most of the remainder of California other than Bay Area counties and a portion of Nevada), initial and boundary concentrations (i.e., effects from outside of the modeling domain), and biogenic emissions within the Bay Area counties.

Impacts of nitrogen deposition from Morgan Hill and Gilroy were not explicitly identified in the modeling, but are part of the contribution referred to as the remainder of Santa Clara County. In the emissions inventory used to prepare emissions for CMAQ, municipalities are not identified separately from the county in which they are located. Estimates of emissions for Morgan Hill and Gilroy were made based on the overlap of boundaries of these cities with grid cells in the modeling domain. Based on these estimates, Gilroy contributes 2% of the Santa Clara County NO<sub>x</sub> emissions, Morgan Hill contributes 3%, San José contributes 79%, and the remainder of Santa Clara County contributes the remainder of the NO<sub>x</sub> emissions (16%). It is reasonable to assume that the impacts from Gilroy and Morgan Hill would be roughly in proportion to their emissions. Of the 17% contribution to nitrogen deposition noted for the remainder of Santa Clara County, therefore, we could expect Gilroy to make up about 1.5% (9% of 17%) and Morgan Hill to make up about 2.7% (16% of 17%).

The contribution of emissions outside of the study area but within Santa Clara County are estimated to grow from 1.1 kg-N/ha/y in the base year to 1.5 kg-N/ha/y in 2035 and 1.7 kg-N/ha/y in 2060. The contribution of emissions from all other Bay Area counties are estimated to grow from 0.7 kg-N/ha/y in the base year to 0.9 kg-N/ha/y in 2035 and 1.0 kg-N/ha/y in 2060.

See **Appendix E** for the complete nitrogen deposition analysis.

## 4.6 Effects on Covered Species

This section describes the potential direct and indirect effects on covered species under the Plan. The amount of incidental take of covered species has been estimated in accordance with the methods described in Section 4.4 *Impact Assessment Methods*. Estimates of incidental take are based on the habitat models developed for 16 of the 19 covered species. These estimates are likely to be inflated for two reasons: habitat models may overestimate the actual extent of suitable habitat (see species profiles in **Appendix D** for details on each model); and suitable habitat may not be occupied by the subject species. For three of the covered species, sufficient information was not available to create geographically explicit (i.e., GIS-based) habitat models. In these cases, worst-case assumptions were used regarding the amount of suitable habitat removed by covered activities.

The major direct impacts on most covered species will result from habitat loss associated with urban and rural development. For wildlife species, the determination of direct and indirect effects on covered species is based on the habitat disturbed for each species. For covered plants, effects are determined both in terms of habitat and effects on known occurrences. **Tables 3-5 and 3-6** and the species accounts (**Appendix D**) provide additional information on specific biological needs for each covered species, including the links between species life-history needs and land cover types used in the analysis. Impacts are described below for groups of species that are subject to similar impact mechanisms. Maximum allowable impacts on covered species for which habitat models have been developed are provided in **Table 4-4**. Maximum allowable permanent and temporary impacts to land cover types and natural communities are provided in **Table 4-2** and **Table 4-3** respectively. Maximum allowable permanent impacts to plant occurrences are provided in **Table 4-6**. Compliance monitoring will document species habitat and plant occurrence impact limits, as well as land cover type and natural community impact limits. Therefore, there will be some overlap in impact accounting (e.g., 1 acre of impact may count both against the serpentine grassland cap and the Bay checkerspot butterfly habitat impact cap).

Descriptions providing additional specificity on the type and location of covered activities anticipated to impact each species are provided; however, these descriptions do not preclude other covered activities from impacting the covered species in different locations. As long as the activity is covered under the Plan, impacts to each covered species are permitted up to the maximum allowable impacts provided in **Table 4-4** and **Table 4-6**.

As discussed in Chapter 1, California State Parks lands are excluded from the permit area. Because of this exclusion, all of the land cover-related analyses in the Plan are based on the study area less State Parks lands unless otherwise noted. The size of the study area less State Parks lands is 460,205 acres. All percentages of impacts discussed below were calculated relative to the 460,205 acre permit area excluding State Parks.

## 4.6.1 Bay Checkerspot Butterfly

Bay checkerspot butterfly populations within the study area have been studied for many years and are relatively well understood. Serpentine grassland on both sides of the Santa Clara Valley provide habitat for this species. The population along Coyote Ridge, by far the largest in size and area, is critical to the persistence of the species. Because the only extant populations occur within the study area, maintaining and managing serpentine grassland habitats is important for the continued existence of this species.

Bay checkerspot butterfly habitat units are divided into two broad categories: core and satellite. The definitions for core and satellite habitat units are adapted from the *Recovery Plan for Serpentine Soil Species of the San Francisco Bay Area* (U.S. Fish and Wildlife Service 1998). Core habitat units are “moderate to large areas of suitable habitat that support persistent Bay checkerspot populations.” Satellite habitat units are “generally smaller and contain less high-quality habitat than core areas, and may occur some distance from core areas.” The status of the core and satellite habitat units is identified as occupied, potential, historic, or unknown. For habitat units defined as “occupied,” species is known to occupy the patch at least in some years. Where individuals were present historically, but now the site is unoccupied and likely no longer suitable, the habitat unit is defined as “historic.” If the site has not been surveyed thoroughly or surveyed in the last ten years, habitat unit was classified as “unknown.” Otherwise suitable patches of serpentine grassland within the dispersal distance of known populations were considered “potential” habitat units if land use management practices such as livestock grazing could improve conditions for the species.

## Direct Effects

Most, but not all, serpentine bunchgrass grassland is considered species habitat (see **Appendix D**, *Modeled Habitat Distribution in Study Area*). As such, most covered activities that remove or alter serpentine grassland habitats are potentially detrimental to this species. Expansion of urban areas or rural residential development is most likely to result in the majority of impacts on this species. For example, suburban and rural residential development could remove suitable habitat—and possibly individuals—along Coyote Ridge and in the Santa Cruz Mountains. In addition, changes in land use or management of serpentine grasslands could also adversely affect the Bay checkerspot butterfly. Changes in land use that are often associated with expansion of urban areas or rural residential development could also be detrimental to the long-term viability of these populations.

A permanent impacts cap of 550 acres is applied to impacts to the serpentine bunchgrass land cover type (**Table 4-2**), the key habitat land cover type for Bay checkerspot butterfly. An additional 91 acres of temporary impacts to serpentine bunchgrass grassland is anticipated and is the maximum impact allowed (**Table 4-3**). Up to 300 acres of permanent impacts and 54 acres of temporary

impacts to Bay checkerspot butterfly modeled habitat mapped (see **Appendix D** and **Table 5-7**) as “occupied” or “potential” are authorized under this Plan (**Table 4-4**), all of which is also serpentine bunchgrass grassland<sup>14</sup>. Impacts to modeled habitat mapped as “historic/unoccupied” and “occupancy unknown” are not subject to this cap because these units:

- are either no longer occupied and have little or no chance of occupancy in the future due to habitat degradation and fragmentation (“historic/unoccupied” units);
- are very small and far from core habitat units and therefore would, at best, support very small populations in only some years (Communications Hill 2 and Valley Christian High School); or
- are surrounded by urban or urbanizing development and are expected to decline in suitability or be lost as covered activities are implemented (Communications Hill 1 and 2, San Martin/Hayes Valley, Southwest Anderson Reservoir, and Valley Christian High School).

Impacts to Bay checkerspot butterfly habitat is further limited to 3% of the unprotected portion (everything except Type 1 open space) of any core or satellite habitat unit targeted for conservation<sup>15</sup> (as defined in **Table 5-7**), with one exception. The exception is the Kirby/East Hills core habitat unit which has an 11% allowance to accommodate the Kirby Landfill expansion of 80 acres. See Chapter 6, Section 6.5, subheading *Condition 13 Serpentine Avoidance and Minimization* for details on serpentine avoidance requirements applied to covered activities.

Impacts are predicted to occur in 12 of the 22 habitat units of Bay checkerspot butterfly in the study area, which constitutes the known range of the species to date. These impacts are distributed across core occupied habitat (**Table 5-7**), satellite occupied habitat, satellite potential habitat, satellite habitat with occupancy unknown, and satellite habitat with historic occurrences. Impacts to critical habitat are detailed in Section 4.7 *Effects on Critical Habitat* below.

A discussion of population trends and key features of the population dynamics of the Bay checkerspot butterfly is presented in **Appendix D**. In **Appendix D**, population estimates for most of Coyote Ridge are presented. Based on this data, the most important core habitats are topographically diverse areas near the ridge top. The higher elevation ridge top and adjacent north slopes and canyons have favorable combinations of high topographic diversity, including large expanses of north-facing slopes, and the coolest and wettest parts of Bay checkerspot butterfly habitat.

The conservation strategy for the Bay checkerspot butterfly includes the acquisition, in fee title or conservation easement, and management of a

<sup>14</sup> The maximum allowable impact to serpentine bunchgrass grassland that is also Bay checkerspot butterfly habitat is 300 acres, leaving 250 acres of allowable impact to serpentine bunchgrass grassland that is not Bay checkerspot butterfly habitat.

<sup>15</sup> These caps do not apply to habitat units in Type 1 open space because loss of habitat will be extremely limited in permanently protected open space (i.e., limited to trail construction and management activities).

substantial portion of the core habitats on Coyote Ridge and the Silver Creek Hills (see Chapter 5, Section 5.4.1 *Bay Checkerspot Butterfly* for details). This acquisition will include most of the core habitat along the ridge tops, which provides high quality habitat for Bay checkerspot butterfly and have historically (since 1984) supported the densest populations of Bay checkerspot butterfly (see **Appendix D**). The lower elevation areas are warmer and drier, and slopes tend to be south and west-facing, with small areas of north-facing slopes in canyons. As a result, these areas have been occupied by far lower densities of Bay checkerspot butterfly than on the ridge top.

All impacts to Bay checkerspot butterfly core and satellite habitat units are expected to be small except for the Kirby Landfill site, as discussed above, and the Pound Site. The proposed development on the Pound Site, approximately 27 acres to accommodate the Mariposa Lodge/Sheriff's Firing Range project, would occur in lower quality habitat in and near developed sites and on dry, south-facing slopes. The ridge tops in this unit support some of the highest quality habitat for Bay checkerspot butterfly and will be avoided for the reasons stated above. Impacts of individual covered activities in core or satellite habitat units are expected to be small (less than 10–20 acres each) because of the limitations on land use development in the County and San José (the two jurisdictions where this habitat occurs) and the requirement to minimize impacts to serpentine bunchgrass grassland (Chapter 6, Section 6.5, subheading *Condition 13 Serpentine and Associated Covered Species Avoidance and Minimization*).

The Kirby Landfill expansion will remove up to 80 acres (11%) of currently unprotected habitat for this species in the Kirby/East Hills core habitat unit. The areas lost to the landfill are primarily south and west-facing slopes, with pockets of north-facing slopes in the canyon. The crests of the north-facing slopes of the developed area have been patchily occupied by Bay checkerspot butterfly, but densities were much lower (100–300 larvae/ha) in 2001 than those along the ridge top (3,000–10,000+/ha) in the 267-acre Butterfly Trust Reserve, which encompasses some of the best quality habitat on Coyote Ridge (S. Weiss pers. comm.). The loss of these 80 acres represents far less than 11% of the prime Bay checkerspot butterfly habitat in the Kirby/East Hills habitat unit. Loss of this habitat is not expected to affect the persistence of the population in this area because it is of relatively low quality and the extent of habitat acquisition and management that will be accomplished through this Plan. Approximately 44% of this unit is already permanently protected.

Impacts to historic/unoccupied Bay checkerspot butterfly habitat units are expected at Communications Hill. Communications Hill 1 and Communications Hill 2 support 230 acres and 25 acres of marginal habitat for the species respectively, all of which is expected to be lost as a result of urban development at that site and habitat fragmentation. Although the species was present at this site historically, it is no longer there due to the site's isolation from core areas and the loss and fragmentation of habitat to date. As previously indicated, loss of serpentine bunchgrass grassland at these two historic/unoccupied habitat units will not count toward the Plan's 300-acre modeled primary habitat impact cap for Bay checkerspot butterfly; however, these impacts will count toward the Plan's 550 acre serpentine bunchgrass grassland impact cap.

The conservation actions for serpentine grassland and serpentine covered species are discussed in detail in Chapter 5. Several aspects of this conservation strategy are relevant to the impacts of nitrogen deposition described below, because these strategies will influence the ways in which excess nitrogen affects covered species. All serpentine grassland incorporated into the Reserve System (both new lands and existing protected areas) will employ proven management techniques such as livestock grazing and prescribed burning. Both techniques can remove excess nitrogen from the community and reduce relative cover of nonnative grasses, maintaining populations of native plants such as dwarf plantain, one of the host plants for Bay checkerspot butterfly, and other serpentine plants (Weiss 2006). Appropriate grazing in some serpentine grasslands, such as Coyote Ridge, has been successful at maintaining high-quality Bay checkerspot butterfly habitat despite elevated nitrogen deposition levels (Santa Clara Valley Transportation Authority 2006). Accordingly, it is expected that management techniques can be used in the future to substantially reduce the adverse effects of increased nitrogen deposition on serpentine grassland communities and thus on Bay checkerspot butterfly and covered serpentine plants.

The most significant threat to the Bay checkerspot butterfly continues to be nitrogen deposition and lack of management to minimize the effects of nitrogen deposition. Key management techniques include livestock grazing, mowing with string cutters, hand-pulling, prescribed fire, and spot applications of herbicide. The ability to conduct long term grazing is central to habitat management. All of these conservation actions are important to maintain and improve Bay checkerspot butterfly habitat but some may have short-term adverse effects. Mowing, hand pulling, and prescribed fire all occur after the Bay checkerspot butterfly has entered diapause in deep soil cracks and under rocks (May–June). Proper use of prescribed fire will have minimal direct negative impacts on Bay checkerspot butterfly populations. Similarly, proper and limited use of herbicide will have minimal direct negative effects on the species. For example, herbicide applications using a graminicide “Envoy” have proven highly effective and are limited to high priority infestations immediately along roads and cover less than 10 acres in any given year.

Recreational trail access creates local disturbance from trail construction, foot traffic, maintenance, and occasional off-trail use. Most likely trail routes will follow existing roads. Additional well designed and maintained trails that will be constructed in the Reserve System will pose minimal threats to healthy Bay checkerspot butterfly populations, even in the smaller satellite populations such as Tulare Hill. Direct effects associated with recreation will be minimized with the implementation of conditions on recreation (see Chapter 6, Section 6.4.6, subheading *Condition 9 Prepare and Implement a Recreation Plan*).

The diversity of serpentine grassland depends on disturbance from many sources, including gophers, cattle, surface erosion, and landslides. The existing grazing regimes provide far more extensive disturbance on an ongoing basis than do the existing or proposed management and recreational uses, and the size and diversity of Coyote Ridge can readily absorb these impacts. Localized

disturbances are usually rapidly recolonized by diverse native plants, including Bay checkerspot butterfly host and nectar plants.

## Indirect Effects

Indirect effects to Bay checkerspot butterfly are expected to result from increased vehicular use (i.e., nitrogen emission deposition, vehicular strikes), increased emissions and deposition from stationary sources of nitrogen, conservation strategy implementation, and other covered activities. Each of these categories of indirect effects is discussed below.

### Nitrogen Deposition

Covered activities that facilitate increased vehicular use or electricity generation in the study area will contribute to on-going nitrogen deposition on Bay checkerspot habitat, especially on Coyote Ridge. The effects of different nitrogen sources were modeled for the study area and the region (see Section 4.4.2 *Direct Effects* subheading *Nitrogen Deposition*, and **Appendix E** for details). New major point sources of nitrogen deposition that could adversely affect serpentine communities and associated covered species could not be adequately analyzed at this time (e.g., new power plant, large diesel generator, or other facilities). To address this, the Wildlife Agencies will have additional review and approval authority over new major point sources of nitrogen that could adversely affect serpentine natural communities and associated covered species (see Chapter 8, Section 8.7.3 *Wildlife Agency Responsibilities*). Nitrogen deposition (N-deposition) in Bay checkerspot butterfly habitat comes from a mix of the regional plume from all upwind sources, including emissions and deposition from stationary sources, and local plumes from road traffic, primarily along U.S. 101. The deposition from any one road is small relative to the regional plume except on habitat within 660–990 feet (200–300 meters), and is primarily the effects of vehicular  $\text{NH}_3$  and  $\text{NO}_2$  emissions (CH2M Hill 2004). Large point sources (i.e., stationary sources) like the Metcalf Energy Center also have small incremental effects. Regional mobile and area sources that are closer to the Bay checkerspot butterfly habitat have larger effects than those from more distant counties; Santa Clara County sources within the study area are estimated to provide 63% of the current deposition (**Appendix E**).

Nitrogen deposition levels are high enough across the study area that all serpentine grassland is at risk, but some areas have higher loads than others. The “critical load” for N-deposition in serpentine grassland, where nonnative grasses have difficulty invading completely, is 5–6 kg-N/ha/yr, as measured with passive samplers (CH2M Hill 2004; Fenn et al. 2010). Tulare Hill and the lower slopes of Coyote Ridge, near U.S. 101, have the highest deposition (15–20 kg-N/ha/yr), and the ridge top above Kirby Canyon receives 10–15 kg-N/ha/year. The reduced N-deposition at the ridge top is a function of its distance from immediate sources (U.S. 101) and its position above the inversion layer on many mornings. In contrast, deposition at Jasper Ridge and at Edgewood County Park (both in

San Mateo County) 1,300 feet from U.S. 280 are 4–5 kg-N/ha/yr. Impacts to Bay checkerspot butterfly habitat resulting from development are most likely to occur at the bottom of slopes, where nitrogen deposition is highest (and therefore habitat quality is lowest).

On-going nitrogen deposition will continue to give nonnative species the ability to dominate native serpentine grasslands, systematically supplanting suitable habitat for covered serpentine plant species and for Bay checkerspot butterfly. It is not possible to precisely determine the nature of the effects of on-going nitrogen deposition on serpentine grassland. While it is likely that on-going nitrogen deposition will favor the growth of nonnative annual grasses over native serpentine species, the resulting change in community composition and habitat quality will depend on several factors. Proportional impacts resulting from on-going deposition will be lower in high pollution zones where impacts may already be acute; similarly, they will be higher in low pollution areas (Weiss 2006). Some of the serpentine grasslands in the study area, such as Tulare Hill and Kirby Canyon, already experience elevated nitrogen deposition levels (CH2M Hill 2004).

With continued N-deposition as a result of growth in the study area and the region, effective grazing management becomes critical to maintaining Bay checkerspot butterfly populations. N-deposition to Bay checkerspot butterfly habitats in Santa Clara County may be above the critical load (as defined above) well into the future, despite efforts to reduce vehicle emissions. It has proven possible to manage the effects of N-deposition on serpentine grasslands in the highest deposition areas on Tulare Hill and low elevation slopes of Coyote Ridge through grazing (S. Weiss pers. comm.). As discussed elsewhere, a flexible grazing regime that seeks to remove a maximal amount of grass each year compensates for high spatial and temporal variability in annual grass production, driven by weather and N-deposition.

The effects of N-deposition on serpentine grasslands and the Bay checkerspot butterfly are well documented (e.g., Weiss 1999). In the absence of grazing, increased growth of annual grasses and thatch build-up lead to decreased cover of host plants, nectar sources, and all native forb species over the course of 1–3 years (Weiss et al. 2007). This habitat shift has been observed every time grazing has been removed in the South Bay, including in the Silver Creek Hills, Santa Teresa Hills, Kirby Canyon Landfill, and in smaller exclosures (Weiss et al. 2007). Losses of host plants and nectar sources lead to population crashes, and ultimately local extinctions. These local extinctions have been observed at Edgewood County Park in San Mateo County. In contrast, grazed areas maintain high native cover and support Bay checkerspot butterfly populations as weather and local topography permit.

The impact of on-going deposition will also depend on the management of specific serpentine grasslands (Weiss 2006). Grazing and burning of grasslands, an important component of the Habitat Plan conservation strategy, are likely to be effective at controlling nonnative species and, consequently, maintaining the relative cover of native serpentine species, including the Bay checkerspot butterfly host plants (Weiss 1999, 2006).

## Vehicular Strikes

Covered activities that facilitate increased vehicular use in the study area will also contribute to an increase in vehicle strikes of Bay checkerspot butterfly. Increased traffic on existing roads is likely to result in higher vehicular strikes. However, the proportional impact of this level of mortality on population dynamics of this species is very small within large core populations such as on Coyote Ridge. Vehicular strikes have a greater impact on adult butterflies dispersing between habitat patches. Existing roads where an increase in vehicle traffic is expected as a result of covered activities and where vehicle strikes with Bay checkerspot butterfly are most likely due to road location, road configuration, and traffic patterns are:

- U.S. 101
- Metcalf Road
- Silver Creek Valley Road
- Monterey Highway
- Santa Teresa Boulevard (expected to be widened during the permit term)
- Dirt ranch roads through or near Bay checkerspot butterfly habitat.
- Roads in residential developments adjacent to butterfly habitat (e.g., Silver Creek Hills, residential areas along Basking Ridge Avenue).

Increased development in open areas between Bay checkerspot butterfly habitat (e.g., Coyote Valley) will also create new hazards and barriers to movement for this species.

## Conservation Strategy Implementation

Indirect effects to the Bay checkerspot and its associated habitat will be similar to those described previously in Section 4.3.7 *Conservation Strategy Implementation*. Implementation of the conservation strategy will increase access to bay checkerspot habitat and may result in increased take. Harm could result from reserve visitors trampling habitat, littering, and collecting nectar and larval host plants. Visitors may also harass adult butterflies during the flight season. However, effects associated with increased access to Bay checkerspot habitat will be greatly reduced by the Plan's conditions on recreation (see Chapter 6, Section 6.4.6, subheading *Condition 9 Prepare and Implement a Recreation Plan*). These effects will be minor and temporary, especially when compared to the net benefits gained from the Reserve System and the educational benefit afforded to the community through limited access to portions of the reserves.

## Other Covered Activities

Indirect effects of other covered activities will be largely avoided by implementation of conditions on covered activities (see Chapter 6, including subheading *Condition 13 Serpentine and Associated Covered Species Avoidance and Minimization*). Conditions placed on construction practices will limit construction dust and erosion. Populations next the Kirby Canyon landfill do not appear to be affected by dust, much of which occurs during the dry season when Bay checkerspot butterfly are in diapause. Erosion is a natural part of the butterfly habitat; nonetheless, conditions on covered activities will avoid erosion impacts. Use of hazardous chemicals will be avoided throughout the Reserve System, including core habitats, except for precisely targeted herbicide applications under the conservation strategy and adaptive management program.

### 4.6.2 California Tiger Salamander, California Red-Legged Frog, Western Pond Turtle

Several species of amphibians and reptiles utilize riverine habitats as discussed above but also use a wide variety of seasonal wetlands, marshes, ponds, and upland habitats during different times of the year. Ponds and wetlands in the study area provide breeding habitat for California tiger salamander, and breeding and year-round habitat for California red-legged frog and western pond turtle. All these species are affected by surrounding land uses because they also need sufficient upland habitat near breeding streams and other aquatic habitats (e.g., ponds, wetlands) to accommodate year-round uses (e.g., refugia, dispersal). For example, western pond turtles need upland habitat an average of 92 feet from breeding sites but up to 1,391 feet for nesting and overwintering (see species account for citations). Pond turtles also require sufficient basking sites in the water for year-round use (Crump 2001; Davis 1998).

The human-influenced water regime often does not facilitate successful breeding (e.g., if seasonal wetlands dry up prematurely, or if waters that were historically seasonal become perennial). Moreover, these water regimes often support nonnative species such as bullfrogs and predatory fish that eat young frogs and salamanders.

## Direct Effects

Covered activities that adversely affect seasonal wetlands, marshes, ponds, streams, or surrounding upland areas may directly affect these species. Individuals could be killed or injured by construction activities. Moreover, the removal or alteration of habitats upland of potential breeding sites may not allow individuals to complete their life cycles or move to other seasonal habitats. Activities that result in the loss of ground squirrel populations (e.g., rodent control) or in the removal or excavation of rodent burrows could result in the direct loss of individuals utilizing upland refugia. Covered activities that remove

vegetation from the edges of wetlands and riparian corridors or vegetation removal within aquatic habitats will reduce habitat heterogeneity and adversely affect these species. Covered activities that isolate breeding pools from adjacent upland habitats will reduce the overall productivity of these species. Isolation of many breeding sites could cause extirpation of local populations. Increased vehicular traffic following road widening or creation of new driveways/access roads within dispersal habitat for reptiles and amphibians will increase the number of individuals that are killed or injured on roadways.

No more than 52 acres of pond and 40 acres of wetland habitat will be permanently affected by covered activities, relative to a total of approximately 1,110 acres of pond habitat and 583 acres of wetland habitat throughout the study area (4.7% of pond and 7% of wetland habitat of the totals in the study area). In addition, no more than 9.4 stream miles will be permanently affected by covered activities, relative to the total of 2,392 miles of stream in the study area (0.4% of the total stream miles in the study area).

Permanent impacts on California tiger salamander modeled breeding habitat will not exceed 77 acres (7% of total modeled breeding habitat in the study area) and temporary impacts will not exceed 14 acres (1% of total modeled breeding habitat in the study area). Permanent impacts on California tiger salamander non-breeding modeled habitat will not exceed 12,855 acres (4% of total non-breeding modeled habitat in the study area) and temporary impacts will not exceed 1,529 acres (less than 1% of total modeled breeding habitat in the study area) (**Table 4-4**).

Permanent impacts on California red-legged frog modeled primary habitat will not exceed 299 acres (3% of total modeled primary habitat in the study area) and temporary impacts will not exceed 116 acres (1% of total modeled primary habitat in the study area). Permanent impacts on California red-legged frog modeled secondary habitat, which includes areas for refugia and dispersal, will not exceed 12,937 acres (4% of total modeled refugia habitat in the study area) and temporary impacts will not exceed 1,489 acres (less than 1% of total modeled secondary habitat in the study area) (**Table 4-4**).

Permanent impacts on western pond turtle modeled primary habitat will not exceed 1,824 acres (2% of total modeled primary habitat in the study area) and temporary impacts will not exceed 440 acres (less than 1% of total modeled primary habitat in the study area). Permanent impacts on western pond turtle modeled secondary habitat will not exceed 7,825 acres (3% of total secondary habitat in the study area) and temporary impacts will not exceed 986 acres (less than 1% of total secondary habitat in the study area) (**Table 4-4**).

Most of the impacts to California tiger salamander, California red-legged frog and western pond turtle occur due to conversion of habitat to developed land cover types within the San José, Morgan Hill and Gilroy planning limits of urban growth. Geographic specificity is provided below for impacts to modeled habitat in the Santa Cruz Mountains, valley floor, and Diablo Range for impacts calculated in GIS (see Section 4.4 *Impact Assessment Methods*). Impacts to

California tiger salamander and California red-legged frog critical habitat are detailed below (see Section 4.7 *Effects on Critical Habitat*).

Impacts to California red-legged frog, California tiger salamander and western pond turtle habitat in the Santa Cruz Mountains are expected to be limited to the Santa Cruz foothills. Impacts to California red-legged frog modeled primary and secondary habitat are expected to occur from dam seismic retrofit on all dams located in the Santa Cruz Mountains and implementation of flood protection projects in Uvas and Gavilan Creeks. Dam and reservoir maintenance is anticipated to impact potential breeding and upland habitat at the Calero, Guadalupe, and Vasona dams. Development within the planning limit of urban growth of Gilroy, rural development, bridge construction/reconstruction, and construction of County Park facilities and infrastructure is expected impact modeled secondary habitat adjacent to modeled primary habitat in the Santa Cruz foothills, especially along Uvas Creek and its lower tributaries.

For California tiger salamander, development within the Gilroy and Morgan Hill planning limits of urban growth, rural development, bridge construction/reconstruction, and construction/reconstruction of County Park facilities and infrastructure is expected to mainly impact modeled upland habitat, with impacts to modeled breeding habitat concentrated on the west side of Uvas Creek and the west side of the City of Morgan Hill. Dam and reservoir maintenance is anticipated to impact potential breeding and upland habitat at Calero and Calero-Fellows Dike.

Impacts to western pond turtle modeled primary and secondary habitat in the Santa Cruz Mountains are expected to be limited to the foothills. Impacts to western pond turtle modeled primary and secondary habitat are expected to occur from dam seismic retrofits on dams in the Santa Cruz Mountains, and implementation of flood protection projects in Uvas and Gavilan Creeks. Dam and reservoir maintenance is anticipated to impact potential habitat at Guadalupe and Vasona Creeks below dams. Development within the planning limit of urban growth of Gilroy, rural development, bridge construction/reconstruction, and construction of County Park facilities and infrastructure is expected impact both modeled primary and secondary habitat, with impacts to concentrated on the west side of Uvas Creek. Impacts locations from Rural Development, all Rural CIP, and all In-Stream CIP cannot be specified at this time. Two western pond turtle known occurrences are expected to be impacted by Gilroy urban development on the west side of Uvas Creek within the Santa Cruz Mountains.

Impacts to California red-legged frog, California tiger salamander, and western pond turtle habitat on the valley floor are expected to occur within the San José, Morgan Hill, and Gilroy planning limits of urban growth. Impacts to California red-legged frog modeled primary and refugia habitat are expected to occur from flood protection projects, vegetation management on lower Llagas Creek, and road upgrades/construction in East Little Llagas Creek. Development within the planning limit of urban growth of Morgan Hill, Gilroy, San José, rural development, bridge construction/reconstruction, and road improvements may impact California red-legged frog secondary habitat adjacent to primary habitat.

Impacts to California tiger salamander breeding and upland habitat are expected to occur on the valley floor within the San José, Morgan Hill, and Gilroy planning limits of urban growth. Impacts to breeding habitat are expected to occur along Upper and lower Llagas Creek, while impacts to upland habitat are expected to occur north and south of West Branch Llagas Creek, between the Uvas and Llagas Creeks throughout the Prince Valle Drain and Lower Miller Slough. All breeding habitat and most upland habitat within the Morgan Hill planning limit of urban growth are expected to be removed. This is expected to include the removal of one known occurrence on the northwest side of the Morgan Hill planning limit of urban growth from urban development. Development within the San José planning limit of urban growth, rural development, bridge construction/reconstruction, and road improvements are expected to impact upland habitat along Guadalupe, Calero, Santa Teresa, Upper Penitencia, Lower Silver, and Coyote creeks (between Lower Silver Creek and just north of Upper Penitencia Creek).

Impacts to western pond turtle primary and secondary habitat are expected to occur from flood protection projects, vegetation management on lower Llagas Creek, and road upgrades/construction in East Little Llagas Creek. Development within the planning limit of urban growth of Morgan Hill, Gilroy, San José, rural development, bridge construction/reconstruction, and road improvements are expected to impact primarily secondary habitat. One western pond turtle known occurrence is expected to be impacted at the Vasona Reservoir.

Impacts to California red-legged frog, California tiger salamander, and western pond turtle in the Diablo Range are limited to the Coyote Watershed, primarily within the San José planning limit of urban growth. For California red-legged frog, this includes impacts to primary and refugia habitat from dam seismic retrofits at Anderson Dam, implementation of flood protection projects on Coyote, Mid-Coyote, Upper Penitencia, Fisher, Lower Silver, Upper Silver, Berryessa, Quimby, Sierra, South Babb, and Thompson creeks; and levee reconstruction on Berryessa, Thompson, Coyote, and Upper Penitencia Creeks. Dam and reservoir maintenance is anticipated to impact potential breeding and upland habitat at the Coyote dam. Development within the planning limit of urban growth of San José, rural development, bridge construction/reconstruction, and construction of County Park facilities and infrastructure are expected to impact the lower stream reaches that serve as California red-legged frog primary habitat and adjacent secondary habitat. This is expected to include impacts to two California red-legged frog known occurrences on Metcalf Creek and Coyote Creek.

San José urban development within the planning limit of urban growth, flood protection projects, and levee reconstruction are expected to impact California tiger salamander upland habitat adjacent to Sierra, Upper Penitencia, Upper Coyote, Upper Silver, Thompson, Fowler, and Quimby creeks. Dam and reservoir maintenance is anticipated to impact potential breeding and upland habitat at the Anderson Dam. Two California tiger salamander known occurrences are expected to be impacted. One is adjacent to Thompson Creek and the other is between Coyote and Thompson creeks.

The impact locations for western pond turtle are similar to those from California red-legged frog. Impacts to western pond turtle primary and secondary habitat are expected to occur from dam seismic retrofits at Anderson Dam, implementation of flood protection projects in Coyote, Mid-Coyote, Upper Penitencia, Fisher, Lower Silver, Upper Silver, Berryessa, Fisher, Quimby, Sierra, South Babb, and Thompson creeks; and levee reconstruction and maintenance in Berryessa, Thompson, Coyote, and Upper Penitencia creeks. Dam and reservoir maintenance is anticipated to impact potential habitat on Coyote Creek below Coyote and Anderson dams. Development within the planning limit of urban growth of San José, rural development, bridge construction/reconstruction, and construction of County Park facilities and infrastructure are expected to impact the lower stream reaches that serve as primary habitat and adjacent secondary habitat.

SCVWD manages flows and diversions to meet water supply objectives. As discussed in Section 4.3.3, dry-back conditions may occur due to fluctuations in seasonal operations. SCVWD generally attempts to avoid stranding of aquatic species when flows are reduced using a ramped schedule for flow reduction. When in-channel flow reductions are made, wildlife may be stranded in isolated pools or downstream reaches. While adult individuals may have time to move out of the area, flow reductions occurring early in the year may affect amphibian egg sacs established on stream margins.

Conversely, during dewatering events, consistent high flows, if started early enough in the year and continued through late spring, may facilitate breeding by providing a reliable water source and may also reduce the potential for stranding. High flows are not expected to affect western pond turtle breeding as this species tends to lay its eggs in uplands away from the active channel. To ensure that impacts to covered amphibian species are avoided and minimized during dewatering events, SCVWD will develop a dewatering plan for review and approval by the Wildlife Agencies prior to commencing a dewatering activity. See Chapter 6 for additional information on the possible issues addressed by the dewatering plan.

The year following a dewatering event, flows are expected to be lower than normal. This will likely reduce the availability of egg laying substrate for amphibians.

Dry-back of channels may also occur due to maintenance activities, although this occurrence is much less common. For example, it may be necessary to reduce reservoir releases when a recharge diversion requires repair. Rapid dry-back could also occur if bypass flow (flow that remains in the channel) at a diversion is blocked by debris or other system failure. However, repairs of downstream diversions are likely to be implemented while maintaining some flow in the channel. Even a catastrophic failure for diverting water at a downstream diversion would likely not trigger a rapid in-stream dry-back; however, receiving ponds may experience a reduction in water level. All planned repairs requiring channel dewatering would incorporate bypass flow.

Amphibian larvae and tadpoles may also be affected by changes in water quality associated with operation of reservoirs and groundwater percolation ponds. These potential effects are discussed in Section 4.3.3. Key issues are increased fine sediments released from reservoirs or ponds that may cover egg sacs if releases are made early in the year. Increased turbidity from sediment and algae may inhibit foraging of adults if releases are made later in the year.

## Indirect Effects

Indirect effects resulting from human population growth and increased urbanization is expected to constrain or eliminate stream, pond, and/or wetland habitats and increase water temperatures, while decreasing sediment transfer and dissolved oxygen. Changes in land use in areas adjacent to breeding sites can reduce the overall habitat quality of upland sites for California tiger salamander, California red-legged frog, and western pond turtle. The rate of natural movement of salamanders among breeding sites depends on the distance between the ponds or complexes of ponds and of the quality of intervening habitat (e.g., salamanders may move more quickly through sparsely covered and open grassland than they can through densely vegetated lands) (Trenham 1998). Loss of habitat connectivity may affect species dispersal movements. An increase in urban development adjacent to breeding habitat would facilitate an increase in predators (e.g., feral cats, raccoons, and skunks) that decrease breeding success and predate reptiles and amphibians. This predation may have a detrimental impact on local populations.

Increased runoff from impervious surfaces into wetland areas carries pollutants that are harmful to reptiles and amphibians, which are particularly sensitive to contaminants and other pollutants in the water. An increase of impervious surfaces within a watershed due to urbanization may result in changes to in-stream flow, temperature, and stream geomorphology. Increases in impervious surfaces can also result in increased water pollutants in local streams, particularly during “first flush” rain events. Herbicides, pesticides, and other toxic materials can cause diminished production or mortality of aquatic covered species. Fertilizers and other organic materials can cause algal blooms that decrease dissolved oxygen levels, while fine sediments may degrade breeding habitat. Changes in land use that reduce natural land cover and increase impervious surfaces in areas adjacent to riverine habitats can also lead to increased disturbance of species (e.g., reduced foraging and reproductive success) due to increased sources of noise, light, neighborhood runoff (e.g., fertilizers, oil), and introduced species.

Covered activities that occur in aquatic habitat (i.e., in-stream capital projects, in-stream operations and maintenance, and monitoring) could facilitate the spread of disease such as chytridiomycosis. Increased public access to habitat supporting California tiger salamander, California red-legged frog, and western pond turtle will increase the potential for harm and harassment, and may also result in increased pollution, predation, and introduction of nonnative species.

### 4.6.3 Foothill Yellow-Legged Frog

Riverine habitats within the study area are subject to human-influenced flows that do not reflect the region's historical water regime. Species that occur in these habitats are usually affected by changes in land use adjacent to the riparian corridor and by the development of permanent infrastructure within the natural floodplain.

#### Direct Effects

Foothill yellow-legged frogs are expected to be affected by projects implemented within the stream channel or that result in the removal of cobblestone substrate or riparian vegetation, particularly in reaches above reservoirs. Ground-disturbing activities, such as maintenance of stream banks, levees, and channel rights-of-way (e.g., bank repair, vegetation management), could increase erosion and sediment discharge that could disrupt breeding of foothill yellow-legged frogs. Projects that place structures in the channel (e.g., culvert installation) or that require stream access may crush individuals or create permanent pooling habitat where higher risk of predation exists for adults, metamorphs, and tadpoles. If pulse flows from reservoirs (to aid migration by juveniles and smolts of listed fish) are released during the foothill yellow-legged frog egg-laying period, they could dislodge egg masses, causing mortality. However, this is unlikely because pulse flows will be release in winter months (January, February, and March) and are intended to simulate natural flow conditions (see Chapter 5 for details). The timing of oviposition (laying of eggs) for foothill yellow-legged frog typically follows the period of high-flow discharge from winter rainfall and snowmelt (Jennings and Hayes 1994; Kupferberg 1996), thus, pulse flows are expected to occur in advance of oviposition.

Although foothill yellow-legged frogs are not currently known to occur downstream of many of the dams in the permit area, remnant populations may be affected by the operation and maintenance of SCVWD's dams. SCVWD manages flows and diversions to meet water supply objectives. As discussed in Section 4.6.2, dry-back conditions may occur due to fluctuations in seasonal operations. There are events that cause operations to fluctuate substantially and rapidly. For example, it may be necessary to reduce reservoir releases when a recharge diversion requires repair. When in-channel flow reductions are made, amphibians may be stranded in isolated pools or downstream reaches that rapidly dry back as flow rapidly declines and the area of wetted channel is decreased. SCVWD generally attempts to avoid stranding of aquatic species when flows are reduced using a ramped schedule for flow reduction. Flow reductions may affect egg masses established on stream margins as well as larval food availability.

Dewatering events could aid breeding by providing a reliable water source and may also reduce the potential for stranding or could impact breeding by scouring egg masses and reducing the algal food base for larvae. To minimize the impacts to foothill yellow-legged frogs, SCVWD will develop a dewatering plan for review and approval by the Wildlife Agencies prior to commencing a dewatering

activity. See Chapter 6 for additional information on the possible issues addressed by the dewatering plan.

Permanent impacts to foothill yellow-legged frog modeled primary habitat will not exceed 1.9 stream miles, or less than 1% of the total modeled habitat for the species within the study area. Temporary impacts are will not exceed 0.7 miles of stream (less than 1%) of modeled habitat. Permanent impacts on foothill yellow-legged frog modeled secondary habitat will not exceed 4.8 miles (less than 1% of total secondary modeled habitat in the study area) and temporary impacts will not exceed 1.3 miles (less than 1% of total modeled secondary habitat in the study area) (**Table 4-4**).

Geographic specificity of impacts to foothill yellow-legged frog is provided below in terms of expected impacts to modeled habitat in the Santa Cruz Mountains, valley floor, and Diablo Range for impacts calculated in GIS (see Section 4.4 *Impact Assessment Methods*).

Impacts to foothill yellow-legged frog in the Santa Cruz Mountains are expected to be limited to the Santa Cruz foothills. Impacts to modeled primary and secondary habitat are expected to occur from dam seismic retrofit at Uvas Dam, Chesbro Dam, Almaden Dam, Calero Dam, and Guadalupe Dam. Impacts from implementation of flood protection projects are expected in Uvas Creek (secondary habitat) and Gavilan Creek (primary and secondary habitat). Dam and reservoir maintenance is anticipated to impact potential habitat at Guadalupe Dam. One known occurrence is expected to be impacted along Uvas Creek, north of its confluence with Bodfish Creek.

Impacts to foothill yellow-legged frog on the valley floor are expected to be limited to modeled secondary habitat in-streams within the San José, Morgan Hill, and Gilroy planning limits of urban growth. Impacts to secondary habitat are expected to occur from implementation of flood protection projects in East Little Llagas, Jones, Lions, West Branch Llagas, West Little Llagas, Alamitos, Arroyo, Canoas, Los Gatos, Randal, and Ross creeks; levee reconstruction in Lower Llagas, Llagas West, Jones, Lions, West Branch Llagas, Alamitos, Guadalupe, Canoas, Randol, and Los Gatos creeks, and the Guadalupe River; vegetation management on lower Llagas Creek; and road upgrades/construction near East Little Llagas Creek. Development within the planning limits of urban growth of Morgan Hill, Gilroy, San José, rural development, bridge construction/reconstruction, and road improvements are expected to impact foothill yellow-legged frog secondary habitat.

Impacts to foothill yellow-legged frog in the Diablo Range are expected to be limited to the Coyote Watershed, primarily within the San José planning limit of urban growth. Impacts are primarily expected to be to secondary habitat and occur from dam seismic retrofits at Anderson Dam; implementation of flood protection projects on Coyote, Mid-Coyote, Upper Penitencia, Fisher, Lower Silver, Upper Silver, Berryessa, Quimby, Sierra, South Babb, and Thompson creeks; levee reconstruction and maintenance in Berryessa, Thompson, Coyote, and Upper Penitencia creeks. Development within the planning limit of urban growth of San José, rural development, bridge construction/reconstruction, and

construction of County Park facilities and infrastructure are expected to impact the lower stream reaches that serve as foothill yellow-legged frog secondary habitat.

## Indirect Effects

Foothill yellow-legged frogs are expected to be indirectly affected by water flow and adjacent land uses within occupied watersheds.

Indirect effects on covered aquatic species are also derived from overall changes in impervious surface in the watersheds during the permit term. An increase of impervious surfaces within a watershed due to urbanization may result in changes to in-stream flow, temperature, and stream geomorphology. Increases in impervious surfaces can also result in increased pollutants entering local streams, particularly during “first flush” rain events. Herbicides, pesticides, and other toxic materials can cause diminished production or mortality of aquatic covered species. Fertilizers and other organic materials can cause algal blooms that decrease dissolved oxygen levels, while fine sediments may degrade breeding habitat. Changes in land use that reduce natural land cover and increase impervious surfaces in areas adjacent to riverine habitats can also lead to increased disturbance of species (e.g., reduced foraging and reproductive success) due to increased sources of noise, light, neighborhood runoff (e.g., fertilizers, oil), and introduced species.

Urban development and agriculture have historically been cited as the cause of degraded watershed health. However, a recent study implicates exurban land use as a significant contributor as well (Lohse et al. 2008). This study found that increases in exurban development within a watershed results in fewer observed areas of high quality in-stream habitat. In addition, the study indicates that exurban development may have a greater relative impact than urban development on stream conditions because exurban development generally occurs in areas that are less developed and have existing high quality habitat (Lohse et al. 2008).

Covered activities that occur in aquatic habitat (i.e., in-stream capital projects, in-stream operations and maintenance, and monitoring) could facilitate the spread of disease such as chytridiomycosis. Increased public access to habitat supporting foothill yellow legged-frogs will also increase the potential for harm and harassment. Increased public access to these areas may also result in increased pollution, predation, and introduction of nonnatives. These effects will be minimized through the implementation of conditions described in Chapter 6.

### 4.6.4 Western Burrowing Owl

Occupied nesting, potential nesting, and overwintering only habitats were modeled for the burrowing owl (see **Appendix D** for habitat requirements). Impacts to the species will differ depending on the type of burrowing owl habitat that is affected. Impacts to different types of burrowing owl habitat will require

different types of conservation actions to ensure the impacts are appropriately offset and that conservation of the species occurs. Impacts are discussed below for the three types of burrowing owl habitat. Impacts are also discussed below for individual owls that may occur in any of these habitat types.

As previously described in Chapter 1, take authorized by permits issued for this Plan that occur within the expanded study area for burrowing owl conservation will be the result of conservation strategy actions implemented for the burrowing owl. Take associated with any of the six other categories of covered activities described in Chapter 2 or conservation actions for species other than the burrowing owl are not covered by this Plan in the expanded study area for burrowing owl conservation.

## Direct Effects

### Occupied Nesting Habitat

Within the Habitat Plan study area and expanded study area for burrowing owl conservation, burrowing owl nesting habitat is limited to grassland, barren, and some agricultural land cover types, that are generally flat with an open view shed and active ground squirrel colonies (see **Appendix D** for habitat requirements). Most of the occupied nesting habitat is within the northern portion of the urban service area of the City of San José.

Based on what is known about the recent distribution of nesting burrowing owls in the study area (DeSante et al. 2007; Townsend and Lenihan 2007; California Natural Diversity Database 2012; Barclay 2007), and the propensity of burrowing owls to forage within 0.5 mile of nest sites during the breeding season (Haug and Oliphant 1990; Rosenberg and Haley 2004), there are an estimated 1,348 acres of occupied nesting habitat (defined as breeding sites and associated essential foraging habitat within 0.5 mile of nest sites) in the study area. This estimate excludes the expanded study area for burrowing owl conservation because the only covered activities that will occur there are those associated directly with burrowing owl conservation. A maximum of 198 acres (15%) of occupied burrowing owl nesting habitat could be lost to covered activities within the Habitat Plan study area. Temporary impacts will not exceed 20 acres (1%) of occupied nesting habitat in the Habitat Plan study area (**Table 4-4**). Areas that are considered burrowing owl nesting habitat but will not be impacted by covered activities include the San José International Airport. All of the expected impacts on occupied burrowing owl habitat from covered activities would occur within the City of San José as a result of urban development.

### Potential Nesting Habitat

There is an estimated 63,751 acres of potential nesting habitat in the study area. A maximum of 4,000 acres (6%) of potential burrowing owl nesting habitat in the permit area may be permanently affected by covered activities. Temporary

impacts will not exceed 604 acres (less than 1%) of potential nesting habitat (**Table 4-4**). This is valley floor habitat that is outside of 0.5 mile of current nest locations but within 7.5 miles (documented movement distances of banded owls in Santa Clara County) of known nest locations (**Figure 5-11**). Impacts to potential nesting habitat will occur primarily as the result of rural residential development in unincorporated County areas, San José, Gilroy, or Morgan Hill. Additional impacts are expected on some types of agricultural lands on the valley floor, where agricultural lands are converted to other uses (housing or commercial).

### **Habitat Used Only for Overwintering**

A maximum of 9,671 acres or 7% of modeled overwintering habitat in the Habitat Plan study area will be permanently affected by covered activities. Temporary impacts will not exceed 762 acres (less than 1%) of modeled overwintering habitat in the Habitat Plan study area (**Table 4-4**). Impacts to overwintering habitat will occur primarily as the result of rural residential development outside of the jurisdiction of San José, Gilroy, or Morgan Hill. Most of the impacts incurred on overwintering habitat will be under the jurisdiction of the County of Santa Clara. Additional impacts may occur as the result of roadway improvements (widening, bridge replacements) or stream maintenance in areas where burrowing owls have been documented using berms or levees along waterways.

### **Impacts on Individual Burrowing Owls**

As described above, take authorization for burrowing owls is primarily limited to loss or degradation of the three kinds of habitat for the species (occupied nesting, potential nesting, and overwintering). All forms of take of individual owls are possible. Loss (death) or injury could occur from implementation of many covered activities if active burrows or nests are not avoided. However, the potential for this is avoided through the implementation of Condition 15, described in Chapter 6. Similarly, filling burrows used by owls when the owls are foraging off site could cause the owl to abandon the site and subsequently die off site if the owls are not able to find new shelter or are otherwise put in harm's way (e.g., excessive exposure leading to predation by other species). Vehicle strikes are also possible on construction sites, particularly when traffic occurs close to active burrows or nests.

Harm or harassment may occur from construction or operations and maintenance activities if these activities disrupt normal foraging or nesting behavior. In some instances, harassment could be so severe that it causes an owl to abandon its nest or its active burrow. The potential for this is minimized through the implementation of Condition 15, described in Chapter 6.

Capture, harm, and harassment may also occur from surveying, monitoring, and management activities within the Reserve System or on managed lands. For

example, active translocation of owls may be used as part of the conservation strategy (see Chapter 5). While allowed under the Plan, this handling activity would capture, harm, and harass owls temporarily while they are being moved. Unsuccessful translocation efforts conducted on an experimental basis may also result in the death of individuals. Impacts on individual burrowing owls will be minimized through the implementation of Condition 15, described in Chapter 6.

Since burrowing owls are protected by the MBTA, take of owls in the form of death or injury will not be allowed under the federal permit for any covered activity<sup>16</sup>. The NCCP permit serves as authorization by CDFG for take of owls consistent with this Plan under the Fish and Game Code.

Until the owl population in the South Bay Population reaches the population growth trend described in Section 5.4.6, the Plan does not cover take of individual owls, except for conservation strategy implementation or if an exception to the passive relocation prohibition is granted (see Chapter 6, Condition 15, subheading *Passive Relocation*). Condition 15 and other avoidance measures described in Chapter 6 (e.g., adoption of speed limits on construction sites) will be used to avoid such impacts. Few exceptions to the passive relocation prohibition are anticipated. These provisions will maximize the possibility of success of the conservation strategy in Chapter 5 by initially preserving owls in the study area as much as possible.

Once the owl population in the South Bay Population reaches the population growth trend as described in Chapter 5, take of individual owls in all forms will be allowed under the Plan for all covered activities (avoidance and minimization measures described in Condition 15 will still be required with the exception that passive relocation will be allowed consistent with the process described in Chapter 6). Since the population is now in decline and because of the limitations of the population viability analysis (PVA) model, it is anticipated that at least a 10 year period is necessary for the conservation activities to have a positive effect and to detect that effect through monitoring and re-running of the PVA.

Once the target growth trend is reached and take of individual owls for all covered activities is allowed, the amount of allowable take will be determined annually by the Implementing Entity in partnership with the Wildlife Agencies based on owl monitoring data and population viability modeling. The amount of take annually will be the number of owls in excess of those needed to maintain the positive growth trend as determined by the PVA (**Figure 4-3**). Based on new data and modeling results, the Implementing Entity and the Wildlife Agencies may increase or decrease the allowable take each year to ensure that the biological goals and objectives of the Plan are met. If the positive growth trend is lost during implementation, take authorization would again be limited to all forms of take associated with the implementation of the burrowing owl conservation strategy or take associated with approved exceptions to the passive relocation prohibition.

<sup>16</sup> If burrowing owl is listed under the ESA, this Plan can at that point serve as a Special Purpose Permit under the MBTA.

Take of burrowing owls resulting from the expiration of temporary management agreements will only be authorized if the targeted population growth described in Chapter 5 is being met. The amount of take would be counted toward the annual take authorized for that year. The only exception to this rule is that take of owls associated with implementation of the conservation strategy may continue and is not counted towards the annual take limit.

## Indirect Effects

Indirect effects resulting from human population growth, increased urbanization of the valley floor, and the continued build out of the three cities covered by the Plan are expected to reduce the quality of western burrowing owl nesting (occupied and potential) and overwintering habitat. The predominant indirect effects on burrowing owls are anticipated to be increased harassment from people, increased vehicle-related disturbance (e.g., of nesting habitat near roads), increased vehicle strikes, isolation of individuals on vacant lots, predation by cats, and increased exposure to humans throughout the study area, including within the Reserve System.

### 4.6.5 Least Bell's Vireo

Least Bell's vireos breed in early successional riparian habitat during the spring and summer months. This habitat is the product of a dynamic riverine environment and is adversely influenced by human-altered riverine systems that minimize disturbance and disallow flooding.

## Direct Effects

Because of the rarity of the species in the study area and the importance of maintaining all individuals that occur, this Plan does not authorize take in the form of direct injury or mortality. The Plan also does not authorize take of nests or eggs (these restrictions are in compliance with the MBTA and California Fish and Game code.) Covered activities may result in take in the form of harm and/or harassment, although these effects will be minimized with the avoidance and minimization measures described in Chapter 6 (see Condition 16 *Least Bell's Vireo*). Covered activities that result in the removal or alteration of riparian habitat within the study area will affect riparian obligate songbirds such as least Bell's vireo. Moreover, any activity that diminishes dynamic riverine events (i.e., floods) that cause natural disturbance and create early successional habitats will reduce the amount of breeding habitat available for this species. This species is not only affected by the amount of breeding habitat available but also by land uses adjacent to the riparian corridor. Impacts on the species will be minimized through the implementation of Condition 16, described in Chapter 6.

Covered activities will not exceed 72 acres of permanent impacts on primary least Bell's vireo modeled habitat, or 2% of the total 3,097 acres of modeled

habitat in the study area. Temporary impacts will not exceed 43 acres (1% of total modeled habitat) of modeled habitat (**Table 4-4**).

Geographic specificity of impacts is provided in terms of impacts to potential habitat calculated in GIS (see Section 4.4 *Impact Assessment Methods*). Impacts to modeled habitat are limited to the Santa Cruz Mountains foothill and the valley floor in the South County. Impacts to least Bell's vireo modeled primary habitat are anticipated to occur along riparian corridors from dam seismic retrofit at Uvas Dam and Chesbro Dam, flood protection projects in Uvas and Llagas Creek watersheds, vegetation management on lower Llagas Creek, and road projects along East Little Llagas Creek.

## Indirect Effects

Least Bell's vireo is expected to be indirectly affected by water flows and adjacent land uses that alter associated riparian habitat within the study area. See Section 4.6.3 *Foothill Yellow-Legged Frog* subheading *Indirect Effects*, above, for a discussion of indirect effects on riverine natural communities and associated riparian corridors. In addition, breeding success can be reduced if adjacent land uses result in nonnative, or feral, nest predators (i.e., cats) or high numbers of parasitic brown-headed cowbirds.

## 4.6.6 Tricolored Blackbird

Tricolored blackbirds breed colonially in freshwater marshes and other wetland habitats with reeds, cattails, or other emergent or non-emergent wetland vegetation (such as blackberry). Further, this species needs foraging habitat adjacent to breeding sites to successfully nest and rear young.

## Direct Effects

Because of the rarity of the species in the study area and its high breeding site fidelity, this Plan does not authorize the removal of historic<sup>17</sup> or active breeding habitat. No direct impacts are allowed to active colonies. Potential tricolored blackbird breeding sites will be directly affected by covered activities that result in the removal or permanent alteration of wetlands, marshes, and vegetated ponds. Conversion of lands from native or agricultural land cover to urban use will result in the degradation of foraging habitat for this species.

Estimated impacts on tricolored blackbird habitat are shown in **Table 4-4**. Permanent impacts on tricolored blackbird modeled primary habitat and secondary habitat will not exceed 276 acres (3%) and 10,317 acres (8%) of

<sup>17</sup> If a pond or wetland has documented breeding within the past 5 years, it will not be directly impacted by covered activities. Best efforts will be used to determine historic use. Best efforts will include at a minimum, a CNDDB records search, discussion with local experts, and investigation of site for historic nesting materials.

modeled primary habitat and secondary habitat in the study area, respectively. Temporary impacts on tricolored blackbird modeled primary habitat and modeled secondary habitat will not exceed 93 acres (1%) and 768 (less than 1%), respectively.

Geographic specificity of impacts is provided in terms of expected impacts to modeled habitat calculated in GIS (see Section 4.4 *Impact Assessment Methods*). Impacts to tricolored blackbird modeled breeding habitat occur to stream reaches where impacts are expected to result from in-stream capital improvement, in-stream operations and maintenance, and road projects. Such covered activities include seismic retrofits, levee reconstruction, vegetation management on lower Llagas Creek, improvements to the Coyote Valley Parkway interchange, and road projects along East Little Llagas Creek.

The majority of the foraging habitat with San José, Morgan Hill, and Gilroy planning limit of urban growth is expected to be removed due to urban development. In the vicinity of Gilroy, this includes modeled foraging habitat adjacent to Uvas, West Branch Llagas, and Llagas creeks. Within the Morgan Hill planning limit of urban growth, all foraging habitat on the valley floor, as well as limited portions in the Santa Cruz foothills, is expected to be impacted. Within the San José planning limit of urban growth, impacts to modeled foraging habitat are limited to the Diablo foothills. This is expected to include modeled foraging habitat in the adjacent Canoas, Upper Silver, Fowler, Evergreen, Upper Penitencia, and Sierra creeks.

No impacts are allowed to active colonies (see Chapter 6, Section 6.6.1, subheading *Condition 17 Tricolored Blackbird*); however, it is anticipated that the colony located in Morgan Hill will likely relocate due to encroachment of development within foraging radius of the breeding site.

## Indirect Effects

The indirect impacts on tricolored blackbird and other native bird species that utilize pond and wetland habitats will be similar to those discussed above in Section 4.6.4 *Western Burrowing Owl*. More specifically, the predominant indirect effects of covered activities on tricolored blackbird are increased harassment from people; vehicle-related disturbance (e.g., of breeding habitat near roads); increased urban predators (e.g., cats, skunks, raccoons); and increased exposure to humans throughout the action area, including within the Reserve System. Edge effects associated with roads and urban development include increased light and noise, which can disrupt breeding and foraging behavior and inhibit communication necessary for successful mating. Changes to existing roadbeds, bridges, and/or barriers and guardrails can change sound characteristics in certain habitats, interfering with acoustic communication for some birds.

## 4.6.7 San Joaquin Kit Fox

The last documented breeding activity of San Joaquin kit fox within the study area occurred in 1992. Breeding may occur in the southeastern portion of the study area, although it is expected to be rare. San Joaquin kit fox may move through the southeastern portion of the study area between areas of known breeding activity outside the study area. Suitable movement habitat for San Joaquin kit fox is defined as annual grassland and oak savanna contiguous with grassland in the Pacheco Creek Watershed. Secondary foraging habitat occurs in agricultural fields and row crops adjacent to grassland areas within this watershed.

Because habitat fragmentation is a significant threat to kit fox, preservation of contiguous tracts of suitable habitat is of primary importance. Ideally, contiguous habitat should be expansive enough to provide both foraging and movement habitat and ultimately to support a viable breeding population (i.e., support one or more kit fox home ranges) should the species expand its breeding range in the future. Known breeding populations north of the study area represent the northernmost extent of the species' range. Maintaining connectivity between those populations and other known breeding populations south of the study area is critical to maintaining genetic diversity in the population. The southern portion of the Plan area is critical to maintaining this linkage.

### Direct Effects

Because of the rarity of the species in the study area and the importance of maintaining all individuals that occur, this Plan does not authorize take of San Joaquin kit fox in the form of injury or mortality. Take is authorized in the form of harm or harassment, although these effects will be minimized with the avoidance and minimization measures described in Chapter 6 (see Section 6.6.1, subheading *Condition 18 San Joaquin Kit Fox*).

Covered activities that occur along the Pacheco Creek corridor and in the portion of the study area south of Henry W. Coe State Park have the potential to affect San Joaquin kit fox. Any new rural development that occurs along the SR 152 corridor could fragment movement habitat and potentially affect movement patterns. Increased vehicular traffic following road widening or creation of new driveways or access roads within movement habitat may increase the risk of injury or death of kit fox on roadways (however, injury or death of kit fox by vehicular collisions is not authorized by this Plan). Any covered activities that require the excavation of burrows or removal of modeled habitat with existing California ground squirrel colonies have the potential to degrade kit fox habitat. Chapter 6, Section 6.6.1, subheading *Condition 18 San Joaquin Kit Fox* reduces the potential to injure or kill kit foxes that might be taking refuge in these burrows.

A maximum of 198 acres of modeled secondary kit fox habitat (less than 1% of modeled habitat), will be permanently removed or degraded and a maximum of 46 acres (less than 1% of modeled habitat) will temporarily affected by covered activities. A maximum of 28 acres of modeled secondary (low use) kit fox habitat (1% of modeled habitat), will be permanently removed or degraded and a maximum of 6 acres (less than 1% of modeled habitat) will temporarily affected by covered activities (**Table 4-4**).

## Indirect Effects

Indirect effects resulting from human population growth in Gilroy and increased urbanization along U.S. 101 south and SR 152 east of Gilroy have the potential to affect kit fox movement through the study area through habitat fragmentation, and may also affect availability of foraging areas and cover. Growing traffic pressures on SR 152 increase the risk of vehicle/kit fox conflict. The presence of road kill attracts predators such as kit foxes and exposes them to increased risk of vehicle strike. Increased risk of fire associated with roads (e.g., accidents and tossed lighted cigarette butts) may also harm or kill kit foxes and temporarily remove habitat.

Recreational uses on Plan Reserves have the potential to disturb denning kit foxes. However, these activities will be prohibited or limited to avoid or minimize adverse impacts on the species (see Chapter 6). Increased noise and lights from urban areas and harassment from pets have the potential to affect kit foxes along the urban-wildland interface. Feral cats increase competition for food and introduce disease.

### 4.6.8 Serpentine Plants

This section describes the direct and indirect effects of the covered activities on covered plants that occur exclusively or primarily in serpentine grassland or serpentine chaparral land cover types. The direct effects are described for each species; indirect effects are described at the end of the section for all serpentine-associated covered plants because indirect effects are similar for the entire group.

## Direct Effects

For each serpentine species listed below, direct effects on known occurrences and suitable habitat are discussed. The discussion includes information on the general location and population estimates of occurrences expected to be affected by covered activities, where these data are available. Population data are often incomplete or out of date due to inconsistent reporting to the state database (CNDDDB). In addition, population sizes reported in one year may not accurately represent long-term averages. Almost all of the covered species discussed in this section are herbaceous annuals or perennials (all but Coyote ceanothus, which is a woody perennial). Both annual and perennial herbaceous plants experience

yearly fluctuations in population numbers due to factors related to climate, disturbance, and chance. For all of these reasons, the population data provided below should be considered as a general overview only. Surveys conducted during Plan implementation of affected and protected populations will yield more accurate population data to be used in tracking impacts, land acquisition, and adaptive management.

In addition to estimates of location and population size of potential impacts, the discussion below includes the maximum allowable occurrence impact limit for each species and the impacts on modeled or suitable habitat.

## **Tiburon Indian Paintbrush**

Potential habitat for Tiburon Indian paintbrush exists in serpentine bunchgrass grassland within the study area. However, the two known extant occurrences in the study area appear to occur on a specific sub-type of serpentine soils (S. Weiss pers. comm.). Two of nine known extant occurrences of Tiburon Indian paintbrush occur within the study area (**Table 4-6**; California Natural Diversity Database 2012). Both of these are located along Coyote Ridge. One is on private land that may be protected as a mitigation site for expansion of the Kirby Canyon Landfill. The second occurrence is on a mitigation site for Bay checkerspot butterfly established by Waste Management, Inc for previous landfill development. Both occurrences are being monitored and managed by the Kirby Canyon Butterfly Trust; neither site is currently permanently protected.

Population estimates for this species exist for all except one of the occurrences. The total estimate of known populations reported in the CNDDDB is 1,687 individual plants (from estimates between 1988 and 2006). More recent surveys, in 2009, of the two occurrences in the study area counted 1,203 individuals. This species will only be affected by the implementation of the conservation strategy. Management actions (i.e., prescribed burning and livestock grazing) on the one occurrence currently under temporary easement may result in temporary effects. These management actions however, will result in a net benefit to the species and impacts are considered minor and temporary. No additional impacts are allowed to the species, even if more occurrences are discovered during the permit term.

All serpentine bunchgrass grassland in the study area is considered potential habitat for this species. A permanent impacts cap of 550 acres (5.3% of the total in the study area) is applied to impacts to the serpentine bunchgrass land cover type. An additional 91 acres (less than 1%) of temporary impacts to serpentine bunchgrass grassland is anticipated and is the maximum impact allowed (**Table 4-3**).

## **Coyote Ceanothus**

Coyote ceanothus is generally found growing on dry slopes in chaparral, grassland, and coastal scrub on serpentine soils. All three known occurrences of

Coyote ceanothus are located within the study area (**Table 4-6**; California Natural Diversity Database 2012). One of these occurrences is located northwest and southwest of Anderson Dam. This occurrence is the largest known. It is mostly on private land although a small portion of it occurs adjacent to Anderson Dam on SCVWD property and a small portion is located on Anderson Lake County Park. Much of the portion of the occurrence on SCVWD property is likely to be permanently impacted by a seismic retrofit of Anderson Dam or major maintenance of the dam. Because of the rarity of this species and the need to quantify the magnitude of the effects, additional analysis was conducted on this occurrence.

The size of the occurrence adjacent to Anderson Dam was estimated using data from previous surveys conducted by SCVWD botanists (2006 and 2007) combined with field surveys conducted on May 5 and 6, 2009. Field data were used to estimate the population density of Coyote ceanothus in three chaparral types mapped on high-resolution aerial photographs (from April 2006). The site includes unburned chaparral and an area of 100–200 acres that burned at varying intensities in 2003. The burn area supports a large population of young plants (most appeared to be 5–6 years old during 2009 surveys) many of which flowered for the first time in the spring of 2010 (U.S. Fish and Wildlife Service 2011).

The 2009 population estimate for this occurrence was 188,475 plants, the vast majority of which (99.5%, or 187,534) were 5–6 years old plants (J. Hillman pers. comm.). The young plants observed during May 2009 appeared to be healthy, and mortality from herbivory or other causes was not observed. The recent 5-year review indicates that many of the individual plants survived to reproductive maturity (U.S. Fish and Wildlife Service 2011). This survival rate is considered conservative because this species is highly adapted to post-burn reproduction and drought conditions and it is resistant to herbivory.

We used overlays of the maximum footprint of the Anderson Dam retrofit and the extent of the Dam Maintenance Program at this site (the boundaries of these projects mostly overlap, but not entirely) to estimate the number of individuals that could be impacted by covered activities. Based on this analysis, we estimate that 3,550 individuals (less than 2% of the total current population) will be affected. Almost all of the plants to be lost are from the 2003/04 crop. With a conservative survival rate for juvenile plants of 50%, the population could be reduced to 94,708 ( $= 187,534/2 + 941$  adults) by the time the covered activities occur (this assumes no recruitment into the population in the meantime, which is unrealistic). Dam seismic safety retrofit and activities associated with the Dam Maintenance Program would remove no more than 3.7% of the western portion of the Anderson population ( $= 3,550/94,708$ ).

A portion of the same occurrence of Coyote ceanothus located east of Anderson Dam could be affected by dam operations following a seismic retrofit. Currently, Anderson Reservoir is operated under storage restrictions because of seismic safety concerns. Under current restricted operations there is only a small chance that the dam would spill and this site could be inundated. However, after the seismic retrofit the reservoir would return to “normal” operations under which

there would be a higher probability that water level of the reservoir would rise to the current vegetation line (approximately equal to spillway elevation) for a portion of the water year. The size of this portion of the occurrence is estimated at 300 individuals, up to 100 of which (33%) may be impacted when the normal reservoir levels are restored (J. Hillman pers. comm.). All of the impacted plants are seedlings or young plants up to 3 years old in 2009. Therefore, all of these individuals germinated on the reservoir shoreline while storage levels were below average.

In summary, up to 3,650 individuals of the occurrence on either side of Anderson Dam could be removed by covered activities, or up to 5% of the total population<sup>18</sup>, whichever is smaller. This standard will be applied to the population as it existed during the 2009 surveys. It will not be applied to any new recruits that are a result of natural or artificial disturbance event such as fire.

Adverse effects to the other two Coyote ceanothus occurrences are not covered under this Plan. However, minor and temporary effects associated with management of these occurrences, if they are incorporated into the Reserve System, would be covered under this Plan since the net effect would be beneficial. No additional impacts are allowed to the species, even if more occurrences are discovered during the Permit term.

The other two occurrences are located on private property near Kirby Canyon Landfill and in Morgan Hill. A portion of the Morgan Hill occurrence is on the Morgan Hill serpentine conservation easement. Based on surveys conducted in 2010 these occurrences have approximately 150 and 600-650 individuals each (U.S. Fish and Wildlife Service 2011).

All serpentine bunchgrass grassland and mixed serpentine chaparral in the study area is considered potential habitat for this species. The maximum allowable permanent impact to serpentine bunchgrass grassland is 550 acres (5.3% of the total in the study area) (**Table 4-2**). The maximum allowable temporary impact to serpentine bunchgrass grassland is 91 acres (less than 1%) (**Table 4-3**). The maximum allowable impact to mixed serpentine chaparral is 131 acres (3.5% of the total in the study area) for permanent impacts and 30 acres for temporary impacts (less than 1% of the total in the study area) (**Tables 4-2 and 4-3**).

## Santa Clara Valley Dudleya

Santa Clara Valley dudleya is restricted to rocky outcrops in serpentine grassland and oak woodland. Land cover types in the study area that could support this species include serpentine/rock outcrop, serpentine bunchgrass grassland and, to a lesser degree, valley oak woodland, coast live oak woodland, and mixed oak woodland and forest. There are currently 207 known extant occurrences in the study area and 209 throughout California (**Table 4-6**; California Natural Diversity Database 2012). Of the extant study area occurrences, two occur in

<sup>18</sup> An impact cap of 5% of the Anderson Dam occurrence (rather than the 3.7% estimated impact) is established to account for error in the estimate of the total population size.

protected open space. One hundred fifty eight (158) occurrences of the 209 known occurrences are not yet recorded in the CNDDDB. All but one of these non-CNDDDB occurrences are on private property on Coyote Ridge (T. Marker pers. comm.), on County Parks parkland, and on Santa Clara Valley Water District land. Of the 209 known extant occurrences, two are in the San Martin area.

Overall, impacts to this species from covered activities are anticipated to be relatively small. The largest impacts will likely be through habitat loss in serpentine bunchgrass grassland and serpentine rock outcrop land cover types. A maximum of 550 acres (5.3% of total in study area) of serpentine bunchgrass grassland and 22 acres (8.5% of total in study area) of serpentine rock outcrop will be permanently affected. A maximum of 91 acres (less than 1% of total in study area) of serpentine bunchgrass grassland and 2 acres (0.6% of total in study area) of serpentine rock outcrop will be temporarily affected (**Table 4-2**).

A maximum of 11 known occurrences (5% of extant occurrences in the study area; **Table 4-6**) have the potential to be impacted by covered activities if no additional occurrences are found during the permit term. Impacts are anticipated to occur from urban development within the planning limit of urban growth, SCVWD canal reconstruction, and from dam and reservoir maintenance and dam seismic safety retrofits in the vicinity of Almaden Dam and Coyote Reservoir.

There are population estimates for 10 of the 11 occurrences to be impacted. These estimates, based on observations between 1992 and 2008, range from 10 to 1,800 plants per occurrence. The total for all 11 is 3,700 (California Natural Diversity Database 2012; J. Hillman pers. comm.). Forty-seven occurrences documented in the California Natural Diversity Database (2012) (those affected by covered activities and those not) have population estimates that total approximately 72,500. Therefore, if all 11 occurrences were impacted by covered activities, this would impact far less than 5% of the known individuals of Santa Clara Valley dudleya. This is likely a large overestimate of impact because there are at least 158 occurrences without data that could include large populations. Therefore, actual impacts are likely less than 1%. New occurrences of this species are discovered frequently (California Natural Diversity Database 2012) so it is highly likely that more occurrences will be discovered during Plan implementation. A maximum of three additional new occurrences (i.e., occurrences not yet known) may be impacted by covered activities if additional new occurrences are protected according to the conditions described in Section 4.4.1 *Direct Effects* subheading *Effects on Plant Occurrences* and protection requirements described in Chapter 5 and **Table 5-16**. For each additional new occurrence impacted, new occurrences of good or better condition than the new occurrences impacted by covered activities must be protected within the Reserve System prior to impacts.

Based on this analysis, the impact on Santa Clara Valley dudleya from covered activities is not expected to have a long-term effect on the species' viability. This is due to the relatively small percentage of the population that will be affected, the low number of individuals affected, and the likelihood that more occurrences will be discovered and protected. The primary habitat of this species is serpentine/rock outcrop. Based on the impact analysis, up to 11% of this land

cover type will be permanently affected by covered activities. However, this proportion is likely an overestimate of impacts because Santa Clara Valley dudleya is often found on serpentine rock outcrops that were too small to be mapped. In addition, at least some of the occurrences within the planning limit of urban growth are likely to prove undevelopable due to the harsh terrain of the rock outcrops on which they occur. Because many more outcrops will be discovered and mapped within the Reserve System during Plan implementation, actual impacts are likely to be much less than 11% of available habitat.

## Fragrant Fritillary

Primary habitat for fragrant fritillary is serpentine bunchgrass grassland and secondary habitat includes annual grassland, northern coastal scrub/Diablan sage scrub, and oak woodland. The study area contains eight of 59 known extant occurrences of this species (**Table 4-6**). Thirty-five (35) of the known occurrences have population estimates from the 1980s, 1990s and 2000s. These range from a low of one individual up to a high of 4,000 individuals, with a total of 16,383 (California Natural Diversity Database 2012).

A maximum of one occurrence in the study area (13% of known occurrences in the study area) that contained eight individuals during a 2000 survey (California Natural Diversity Database 2012) may be impacted by urban development (it is located within the planning limit of urban growth). In addition, it is possible that newly discovered occurrences of this species could be impacted by covered activities during Plan implementation. A maximum of two additional new occurrences (i.e., occurrences not yet known) may be impacted by covered activities if additional new occurrences are protected according to the conditions described in Section 4.4.1 *Direct Effects* subheading *Effects on Plant Occurrences* and protection requirements described in Chapter 5 and **Table 5-16**. For each additional new occurrence impacted, new occurrences of good or better condition than the new occurrences impacted by covered activities must be protected within the Reserve System prior to impacts.

Impacts to habitat can also occur from other covered activities. A maximum of 550 acres of modeled primary habitat and 2,729 acres of modeled secondary habitat (6% and 2% of modeled habitat, respectively) may be permanently affected. A maximum of 59 acres of modeled primary habitat and 655 acres of modeled secondary habitat, less than 1% of each of total modeled primary and secondary habitat, may be temporarily impacted (**Table 4-4**). Dam and reservoir maintenance could result in small permanent and temporary impacts to modeled species habitat.

## Most Beautiful Jewelflower

Suitable habitat for this species includes primary habitat in serpentine bunchgrass grassland, serpentine rock outcrops/barren, and mixed serpentine chaparral. Secondary habitat includes non-serpentine rock outcrops. Of the 86 total known extant occurrences of this species known, 39 of them are located in the study area

(**Table 4-6**; California Natural Diversity Database 2012; J. Hillman pers. comm.). Up to six occurrences (7% of the total known) may be impacted by covered activities if additional occurrences are not discovered during the permit term. One of these is located within the planning limit of urban growth in Morgan Hill, northeast of Chesbro Reservoir, one is located within the expected impact area for SCVWD canal reconstruction, and four are located near Almaden, Anderson, and Chesbro dams and may be impacted by seismic retrofit and/or dam maintenance activities during the permit term.

In addition, it is possible that newly discovered occurrences of this species could be impacted by covered activities during Plan implementation. A maximum of two additional new occurrences (i.e., occurrences not yet known) may be impacted by covered activities if additional new occurrences are protected according to the conditions described in Section 4.4.1 *Direct Effects* subheading *Effects on Plant Occurrences* and protection requirements described in Chapter 5 and **Table 5-16**. For each additional new occurrence impacted, new occurrences of as good or better condition than the new occurrences impacted by covered activities must be protected within the Reserve System prior to impacts.

Forty of the 86 known occurrences have population estimates. These range from 1 individual to 10,000; however, most estimates are in the low hundreds. These estimates were gathered between 1991 and 2008. The total estimate for all occurrences is 44,549. The six occurrences that will be impacted have a total population estimate of 1,076. Therefore, impacts to this species as a whole will be relatively small. In addition to the 86 recorded occurrences, there are 68 “jewelflower” occurrences on one private property that have not been identified to species, but are either most beautiful jewelflower or Metcalf Canyon jewelflower. This property will be acquired and included in the Reserve System. This also reduces the likely overall impact of covered activities on this species.

A maximum of 550 acres (4% of the total in the study area) of primary modeled habitat will be permanently affected by covered activities, and a maximum of 92 acres (less than 1% of the total in the study area) of primary modeled habitat will be temporarily affected (**Table 4-4**). No secondary habitat is anticipated to be impacted. Dam and reservoir maintenance and dam seismic safety retrofits could result in permanent and temporary impacts to habitat in the vicinity of the Coyote, Almaden, and Anderson dams.

## Metcalf Canyon Jewelflower

Suitable habitat for Metcalf Canyon jewelflower includes serpentine bunchgrass grassland and serpentine rock outcrops. There are 11 known extant occurrences of Metcalf Canyon jewelflower, 10 of which occur within the study area (**Table 4-6**; California Natural Diversity Database 2012). There is one occurrence near Lexington Reservoir that is outside the study area. Of these 10, the maximum allowable permanent impact is two (20% of known occurrences) occurrences under the Plan (**Table 4-6**). No additional impacts are allowed to this species, even if more occurrences are protected during the Permit term. Population estimates are available for only four of the known occurrences; three

of these estimates date from 1989 and one from 2006. They are 27, 40, 1,000, and 5,000, for a total of 6,067 individuals (California Natural Diversity Database 2009).

CNDDDB occurrence numbers 4 and 8 are expected to be impacted by SCVWD operations and maintenance activities on the Coyote Canal. Occurrence 8 was surveyed in 1989 and found to have 40 individuals. Occurrence 4 was surveyed in 1989 and found to include 5,000 individuals. Impacts to these occurrences are expected to be “partial impacts” as defined in Condition 20 of Chapter 6.

A maximum of 550 acres (7% of the total in the study area) of modeled primary habitat will be permanently affected, and a maximum of 62 acres (less than 1% of the total in the study area) of modeled primary habitat will be temporarily affected by covered activities (**Table 4-4**).

## Smooth Lessingia

Suitable habitat for smooth lessingia includes serpentine bunchgrass grassland and serpentine rock outcrops. All 39 extant occurrences of smooth lessingia are located within the study area, which comprises the entire range of this species (**Table 4-6**; California Natural Diversity Database 2012). There are estimates for 22 of these occurrences and the numbers for some of them are quite high (10,000 for two and 57,400 for another). There are also lower numbers in the 100–200 range, but on the whole this species tends to have high numbers where it occurs. The total of the 22 occurrences with estimates is 101,629 individuals, and these estimates are mostly from 2003–2008, although there are three from 1996, 1999 and 2000 (California Natural Diversity Database 2012; J. Hillman pers. comm.).

Impacts from covered activities may occur on a maximum of six occurrences from SCVWD canal reconstruction, dam seismic safety retrofits, or dam maintenance activities to Almaden Dam, Anderson Dam, Calero Main Dam, and Chesbro Dam (**Table 4-6**) if no additional occurrences are discovered. Prior to impact, two occurrences must be protected for every permanent impact to one occurrence. Dam retrofits and maintenance activities will impact an estimated 6,000 individual plants (30 at Almaden Dam, 3,600 at Chesbro Dam, 175 at Calero Main and 5,800 near Anderson Dam), based on 2006 surveys conducted by SCVWD. Canal reconstruction is estimated to impact approximately 6,500 individuals, according to surveys conducted by SCVWD in 2008.

In addition, it is possible that newly discovered occurrences of this species could be impacted by covered activities during Plan implementation. A maximum of three additional new occurrences (i.e., occurrence not yet known) may be impacted by covered activities if additional new occurrences are protected according to the conditions described in Section 4.4.1 *Direct Effects* subheading *Effects on Plant Occurrences* and protection requirements described in Chapter 5 and **Table 5-16**. For each additional new occurrence impacted, new occurrences of as good or better condition than the new occurrences impacted by covered activities must be protected within the Reserve System prior to impacts.

Some covered activities may create partial impacts to smooth lessingia occurrences as defined in Chapter 6, Section 6.6.2, subheading *Condition 20 Avoid and Minimize Impacts to Covered Plant Occurrences*. If partial impacts occur, some of these may not count as a permanent impact and therefore would not require preservation of other occurrences to offset them. If partial impacts occur, the requirements in Condition 20 must be followed, including monitoring of the affected occurrence to ensure that the occurrence continues to be viable.

A maximum of 2 acres (less than 1% of the total in the study area) of serpentine/rock outcrop will be temporarily affected, and a maximum of 22 acres (8.5% of the total in the study area) will be permanently affected by covered activities. A maximum of 91 acres (less than 1% of the total in the study area) of serpentine bunchgrass grassland will be temporarily affected, and maximum of 550 acres (5.3% of the total in the study area) will be permanently affected by covered activities (**Tables 4-2 and 4-3**).

A maximum of 550 acres (5% of the total in the study area) of modeled primary habitat will be permanently affected, and a maximum of 68 acres (less than 1% of the total in the study area) will be temporarily affected by covered activities (**Table 4-4**).

## Mt. Hamilton Thistle

Primary habitat for Mt. Hamilton thistle is serpentine seeps or serpentine soils or grasslands within 25 feet of riverine habitat. There are 48 known extant occurrences of Mt. Hamilton thistle throughout its range and 40 of them are in the study area (**Table 4-6**; California Natural Diversity Database 2012; J. Hillman pers. comm.). The maximum impact limit for this species is six occurrences (12% of known occurrences) if no additional occurrences are discovered during the permit term. This includes occurrences within the planning limit of urban growth, two that will be impacted by SCVWD canal reconstruction, and one that is adjacent to, and likely to be affected by, the seismic retrofit of Anderson Dam. The six impacted occurrences are all located east of U.S. 101. It is expected that at least one of the impacts to Mt. Hamilton thistle will qualify as a partial impact (as defined in Condition 20 of Chapter 6) and therefore would not count toward the total impacted occurrences for the species.

In addition, it is possible that newly discovered occurrences of this species could be impacted by covered activities during Plan implementation. A maximum of two additional new occurrences (i.e., occurrences not yet known) may be impacted by covered activities if additional new occurrences are protected according to the conditions described in Section 4.4.1 *Direct Effects* subheading *Effects on Plant Occurrences* and protection requirements described in Chapter 5 and **Tables 5-16**. For each additional new occurrence impacted, new occurrences of good or better condition than the new occurrences impacted by covered activities must be protected within the Reserve System prior to impacts.

There are population estimates for 36 occurrences of this species, from as early as 1983 up to as recently as 2008. The range in population is from 1 to 4,500, and totals 28,962. There are estimates for all six potentially impacted occurrences, totaling approximately 9,500 individuals (California Natural Diversity Database 2012; J. Hillman pers. comm.).

Impacts to modeled habitat are limited to a maximum of 26 acres of permanent impacts (5% of the total habitat modeled in the study area) and 4 acres of temporary impacts (less than 1% of the total habitat modeled in the study area) (**Table 4-4**). Included in these impact limits are impacts associated with recharge operations, dam and reservoir maintenance and dam seismic safety retrofits, which were difficult to estimate because of the broad scale of Plan land cover mapping.

The Mt. Hamilton thistle is one of eight covered species addressed in the *Recovery Plan for Serpentine Species of the Bay Area* (U.S. Fish and Wildlife Service 1998). At the time the recovery plan was written, known occurrences of Mt. Hamilton thistle were distributed nearly evenly on the east and west side of U.S. 101. Many more occurrences have since been identified, most of which are located on the serpentines areas in and around Coyote Ridge on the east side of U.S. 101. It is for this reason that the Plan will focus conservation efforts for the Mt. Hamilton thistle on acquiring occurrences on the east side of U.S. 101 (J. Hillman pers. comm.).

## Indirect Effects

One of the primary, and possibly the most critical, potential indirect effects to serpentine plants is nitrogen deposition, as described above, under Bay checkerspot butterfly Indirect Effects (Section 4.6.1 *Bay Checkerspot Butterfly*). Nitrogen deposition associated with use of local and regional roads has led to an increase in nitrogen availability in the nitrogen-depleted serpentine soils. In turn, this has led to an increased ability for nonnative plants, primarily nonnative annual grasses, to establish in the serpentine, and outcompete the covered serpentine endemic species.

Additionally, new trails and facilities associated with the Reserve System will increase public access to areas that had not previously been accessible. An increase in foot traffic in reserves may increase the risk of invasion by nonnative species and could facilitate opportunities for illegal collection of covered species.

Indirect effects could also occur from increased risk of wildfire in serpentine species' habitat. However, since most native plants in these habitats are adapted to a burn regime, this impact may not be detrimental to certain covered plant species.

## 4.6.9 Non-Serpentine Plants

Non-serpentine plant species covered by the Plan have a wide variety of habitat requirements and are distributed throughout the study area, though typically outside urban areas. The potential for covered activities to permanently remove individuals or habitat varies with the species. Because these species are often found in the low hills east of U.S. 101 or in the Santa Cruz Mountains, several of the issues discussed for serpentine plants and Bay checkerspot butterfly also apply to this suite of species. Direct effects for each species are discussed individually below; indirect effects are discussed at the end of the section for all the species together, as these effects generally impact the entire group similarly.

### Direct Effects

Plant occurrences in habitats other than serpentine grassland could be affected by any of the Covered Activities; however, they are most likely to be affected by rural residential development. Rural residential development is expected to remove suitable habitat for these species, particularly in the Santa Cruz Mountains and in some of the low hills east of U.S. 101 that are unprotected. Moreover, the increase in infrastructure that is associated with rural development (e.g., roads, water conveyance) is expected to permanently remove suitable habitat and could kill individuals if they are not discovered prior to construction. Because most of these species occur in areas where the general land use is not likely to change during the permit term, long-term population viability should not be affected. Operations and maintenance activities that require accessing areas off established roadways could cause individuals to be crushed or habitat to be altered. If such activities require vegetation clearing or ground disturbance, they could remove suitable habitat for covered plant species. Additionally, Plan implementation activities, such as controlled burns and livestock grazing, could affect covered plant species. The Plan also includes many types of monitoring which can occasionally have impacts on individual plants in the form of trampling or soil disturbance. In both these cases, the benefits from Plan implementation are expected to greatly outweigh any negative effects of implementation.

For each non-serpentine species below, direct effects on known occurrences and suitable habitat are discussed. The discussion includes information on the general location and population estimates of occurrences expected to be affected by covered activities, where these data are available. Population data are often incomplete or out of date due to inconsistent reporting to the state database (CNDDB). In addition, population sizes reported in one year may not accurately represent long-term averages. All of the covered species discussed in this section are annuals. Annuals experience yearly fluctuations in population numbers due to factors related to climate, disturbance, and chance. For all of these reasons, the population data provided below should be considered as a general overview only. Surveys conducted during Plan implementation of affected and protected occurrences will yield more accurate population data to be used in tracking impacts, land acquisition, and adaptive management.

In addition to estimates of location and population size of potential impacts, the discussion below includes the maximum allowable occurrence impact limit for each species and the impacts on modeled or suitable habitat.

## Loma Prieta Hoita

Suitable habitat for Loma Prieta hoita occurs in mixed oak woodland and coast live oak forest and woodland (primary habitat) and northern mixed chaparral/chamise chaparral and mixed serpentine chaparral (secondary habitat). Fourteen of 26 known extant occurrences of this species are located in the study area. No occurrences of this species will be impacted by covered activities if additional occurrences are not discovered during the permit term (**Table 4-6**). It is possible that newly discovered occurrences of this species could be impacted by covered activities during Plan implementation. A maximum of two additional new occurrences (i.e., occurrences not yet known) may be impacted by covered activities if additional new occurrences are protected according to the conditions described in Section 4.4.1 *Direct Effects* subheading *Effects on Plant Occurrences* and protection requirements described in Chapter 5 and **Table 5-16**. For each additional new occurrence impacted, new occurrences of as good or better condition than the new occurrences impacted by covered activities must be protected within the Reserve System prior to impacts. Of the 26 known occurrences, 18 have population estimates, most of which are from 2004–2006, with one from 1995 and one from 2002. They range from 20 to 3,000 individuals and total 7,260 (California Natural Diversity Database 2012).

Maximum allowable impacts to modeled primary habitat are 2,117 acres (2%) of permanent impacts and 413 acres (less than 1 %) of temporary impacts. A maximum of 266 acres (1%) of modeled secondary habitat may be permanently impacted, and 60 acres (less than 1%) may be impacted temporarily impacted (**Table 4-4**).

## Indirect Effects

New trails and facilities associated with the Reserve System will increase public access to areas that had not previously been accessible. Such an increase in foot traffic and trails could increase the risk of invasion by nonnative species which can result in the permanent loss of habitat for covered species. Increased access also increases the possibility of collection, disturbance, injury or mortality from trampling by humans or domestic animals (e.g., dogs, horses, etc.).

Indirect effects could also occur from increased risk of wildfire in covered species' habitat. However, since most native plants in these habitats are adapted to a burn regime, this impact may not be detrimental to certain covered plant species.

## 4.7 Effects on Critical Habitat

Critical habitat is defined in Section 3 of the ESA as:

1. The specific areas within the geographical area occupied by a species at the time it is listed in accordance with the Act, on which are found those physical or biological features
  - a. essential to the conservation of the species and
  - b. that may require special management considerations or protection; and
2. Specific areas outside the geographical area occupied by a species at the time it is listed, upon a determination that such areas are essential for the conservation of the species.

A summary of effects on critical habitat is provided in **Table 4-9**. A discussion of effects of covered activities on critical habitat in the study area is provided below.

### 4.7.1 Bay Checkerspot Butterfly

Critical habitat was redesignated for Bay checkerspot butterfly in 2008 [73 FR 50405–50452]. Most of the designated critical habitat is within the study area boundary (**Figure 4-4**). In fact, 10 of the 13 units or 16,601 acres of the designated 18,293 acres (91%) fall within the study area. This critical habitat includes serpentine and California annual grasslands that stretch from southern San José to just south of Morgan Hill. The five primary constituent elements for Bay checkerspot butterfly are:

1. The presence of annual or perennial grasslands with little to no overstory that provide north–south and east–west slopes with a tilt of more than 7 degrees for larval host plant survival during periods of atypical weather (for example, drought).
2. The presence of the primary larval host plant, dwarf plantain (*Plantago erecta*), and at least one of the secondary host plants, purple owl’s-clover (*Castilleja densiflora*) or exserted paintbrush (*Castilleja exserta*), are required for reproduction, feeding, and larval development.
3. The presence of adult nectar sources for feeding.
4. Soils derived from serpentinite ultramafic rock (Montara, Climara, Henneke, Hentine, and Obispo soil series) or similar soils (Inks, Candlestick, Los Gatos, Fagan, and Barnabe soil series) that provide areas with fewer aggressive, nonnative plant species for larval host plant and adult nectar plant survival and reproduction.
5. The presence of stable holes and cracks in the soil, and surface rock outcrops that provide shelter for the larval stage of the Bay checkerspot butterfly during summer diapause.

The 16,601 acres of designated critical habitat for the Bay checkerspot butterfly in the study area includes 7,616 acres of modeled habitat for the Bay checkerspot butterfly and 8,985 acres of additional areas outside the Plan's modeled habitat. Critical habitat areas that do not support serpentine soils and vegetation are included in the designation because USFWS concluded that they "likely play an important role in dispersal of adult butterflies from one habitat patch to another" (73 FR 50405-50452). Although Bay checkerspot butterfly tend to show high fidelity to patches of serpentine grassland, a small but important number (estimated to be 10% or less), will leave serpentine bunchgrass areas (see **Appendix D**).

Critical habitat as defined by the primary constituent elements may be affected by covered activities as described below.

Continued urban and rural growth on the east side of Coyote Creek in and near the Silver Creek hills would result in the conversion of critical habitat into developed land cover types. Any conversion of habitat would also result in a complete loss of primary constituent elements. An increase in vehicles on local highways, as well as highways throughout the San Francisco Bay Area, will result in increased nitrogen deposition which would reduce the quality of designated critical habitat. In addition, several of the critical habitat units are near urban areas which may limit the types of management (i.e., fire) used to return these sites to a more natural state. Public access to Plan reserves would further affect critical habitat units by facilitating transfer of invasive plants into areas that were previously inaccessible, or by treading on individuals, larvae, and host plants. However, this Plan targets the acquisition of most of the core habitat areas identified in this Plan. Grazing will be a key management tool used within reserves and it is expected that careful grazing management will successfully rehabilitate degraded serpentine areas and protect existing habitat from the stressors of nitrogen deposition and competing plants. Furthermore, within the Reserve System, trails and recreational use will only be allowed if it is consistent with the biological goals and objectives of the Plan. As such, the potential for impacts associated with recreation will be minimized in reserves. Protection of critical habitat and proper management will result in the preservation of the primary constituent elements of Bay checkerspot butterfly habitat within the Reserve System.

Impacts to modeled primary Bay checkerspot butterfly habitat are capped at 300 acres and impacts to serpentine bunchgrass grassland are capped at 550 acres. No more than 550 acres (less than 3%) of Bay checkerspot butterfly critical habitat in the study area associated will be lost as a result of covered activities in this Plan (**Table 4-9**). This estimate does not include nitrogen deposition impacts.

The impact analysis does not identify impacts by critical habitat unit; however, impacts to Bay checkerspot butterfly habitat is limited to 3% of the unprotected portion (everything except Type 1 open space) of any core or satellite habitat unit targeted for conservation (as defined in **Table 5-7**) with the exception of the Kirby/East Hills core unit which has a 11% allowance to accommodate the Kirby Landfill expansion (80 acres) and the Pound Site core habitat unit which has an

13% allowance to accommodate the Mariposa Lodge/Sheriff's Firing Range project (approximately 27 acres).

There are more core habitat units identified for this Plan than critical habitat units, but core habitat does largely overlap with critical habitat designations. The impact caps for each core habitat unit are intended to ensure that core habitat will continue to function as habitat for the butterfly. Therefore, it is expected that limits on core habitat development will also ensure that units of critical habitat continue to function for Bay checkerspot butterfly.

**Table 5-21** describes estimated acreages of Bay checkerspot butterfly critical habitat that will be preserved within the Reserve System by unit. As shown, no conservation for critical habitat units 9b and 12 is anticipated for this Plan. Unit 9b is located in the foothills of the Santa Cruz Mountains at the southern tip of the Coyote Valley Urban Reserve, just outside of the planning limit of urban growth for the City of San José. It also borders a portion of the Coyote Valley Greenbelt. This area is unincorporated and is characterized by the Ranchland/Woodland land use type (**Figure 2-2**) which allows a maximum development density 1 dwelling unit per 20 acres. No water or transportation projects are planned for this site (**Figures 2-6 and 2-7**). While it is possible that this unit could be affected by rural development permitted by this Plan, due to the location of the site (outside urban areas), development density requirements, and the small size of the unit (only 56 acres), it is not expected that this unit will experience much development.

Unit 12 is located in the foothills of the Santa Cruz Mountains between the planning limits of urban growth for the Cities of Morgan Hill and Gilroy. A portion of this unit borders the western edge of the unincorporated community of San Martin. This unit is in unincorporated lands and is characterized by the Ranchland/Woodland land use type. No water or transportation projects are planned for this site (**Figures 2-6 and 2-7**). Approximately 52% of unit 12 is currently protected as Type 1 Open Space. While it is possible that this unit could be affected by rural development permitted by this Plan, due to the location of the site (outside urban areas) and development density requirements, it is not expected that this unit will experience much development.

## 4.7.2 California Tiger Salamander

Critical habitat was designated for the central population of California tiger salamander in 2005 [70 FR 49380–49458]. There are eight critical habitat units within the study area (East Bay Region Units 5–12) (**Figure 4-5**). The study area supports 28,096 acres of critical habitat, including 92 acres of modeled breeding habitat and 27,235 acres of modeled non-breeding habitat (**Table 4-9**).

The three primary constituent elements for California tiger salamander are:

1. Standing bodies of fresh water including natural and manmade (e.g., stock) ponds, vernal pools, and other ephemeral or permanent water bodies which

typically support inundation during winter rains and hold water for a minimum of 12 weeks in a year of average rainfall.

2. Upland habitats adjacent and accessible to and from breeding ponds that contain small mammal burrows or other underground habitat that CTS depend upon for food, shelter, and protection from the elements and predation.
3. Accessible upland dispersal habitat between occupied locations that allow for movement between such sites.

Nearly all the critical habitat units are in or on the periphery of urban areas, meaning that urban development, rural residential development, and any associated infrastructure (e.g., roads, water conveyance) could affect this critical habitat. Such impacts are less likely in units 11 and 12 because these areas are in the far east hills of the study area where fewer covered activities are anticipated. Operations and maintenance activities will affect all units in the study area, particularly those associated with aquatic resources that serve as potential breeding habitat. Covered activities that result in a change in land use adjacent to potential breeding habitat, particularly if the change in land use includes control or elimination of burrowing mammals, would result in a loss of important upland habitat for the species, including the primary constituent elements listed above, and reduce the overall habitat quality for year-round occupation. Avoidance and minimization measures described in Chapter 6 will reduce the potential for indirect impacts on critical habitat.

No more than 272 acres (1%) of all California tiger salamander critical habitat in the study area will be affected by covered activities in this Plan (**Table 4-9**). The impact analysis does not identify impacts by critical habitat unit; rather, it identifies impacts grouped by all critical habitat present in the study area. However, 97% of all critical habitat was also mapped as breeding or non-breeding habitat for this Plan. Impacts to breeding and non-breeding habitat are quantified and discussed in Section 4.6.2 *California Tiger Salamander, California Red-legged Frog, Western Pond Turtle*.

**Table 5-21** also describes estimated acreages of California tiger salamander critical habitat that will be preserved within the Reserve System by unit. As shown, little to no critical habitat in units EB-9, EB-10A, and EB-11 is anticipated to be included in the Reserve System. Unit EB-9 is located in the Diablo Range east and south of Coyote Reservoir. A large portion of unit EB-9 is located in the Palassou Ridge Open Space Preserve (Type 2 Open Space). The portion south of the reservoir is split across Coyote Lake Harvey Bear Ranch County Park (Type 3 Open Space) and the Ranchland/Woodland land use type. No water or transportation projects are planned for this site (**Figures 2-6 and 2-7**). Open space areas account for approximately 66% of this unit. While it is possible that some covered activities occur within the open space, it is expected to be minimal. It is also possible that this unit could be affected by rural development permitted by this Plan. However, due to the location of the site (outside urban areas), development density requirements, and portion of this unit that is available for development (approximately 34%), it is not expected that this unit will experience much development.

Unit EB-10A is located in the foothills of the Santa Cruz Mountains between the planning limits of urban growth for the Cities of Morgan Hill and Gilroy. This unit largely overlaps Bay checkerspot critical habitat unit 12. Permanent impacts to Bay checkerspot butterfly modeled primary habitat that overlaps Bay checkerspot butterfly critical habitat is capped at 300 acres to meet regulatory standards (**Table 4-9**). Subsequently, it is likely that permanent impacts in the portion of California tiger salamander critical habitat unit EB-10A that overlaps with Bay checkerspot critical habitat unit 12 will be minimal. A portion of this unit borders the western edge of the unincorporated community of San Martin. This unit is in unincorporated lands and is characterized by the Ranchland/Woodland land use type. No water or transportation projects are planned for this site (**Figures 2-6 and 2-7**). None of this unit is currently protected by any type of open space. While it is possible that this unit could be affected by rural development permitted by this Plan, due to the location of the site (outside urban areas) and development density requirements, it is not expected that this unit will experience much development.

Unit EB-11 is located in the Diablo Range east and somewhat south of unit EB-9. Approximately 94% of this site currently located within Henry Coe State Park. Activities occurring within Henry Coe State Park are not covered by this Plan. As such, a maximum of 6% of this site could be affected by the covered activities of this Plan. However, no water or transportation projects are planned for this site (**Figures 2-6 and 2-7**). This site is located in the far east portion of the study area and is unlikely to receive much rural development. As such, it is not expected that this unit will be substantially affected by the covered activities of this Plan.

### 4.7.3 California Red-Legged Frog

Critical habitat was designated for California red-legged frog in 2010 [75 FR 12816–12959]. The two main critical habitat units in Santa Clara County are STC-1 (52,283 acres) which is entirely within Santa Clara County and STC-2 (204,718 acres in total, 97,214 acres of which are in the study area) which extends west into Stanislaus County and south into San Benito County (**Figure 4-6**). Santa Clara County also contains a small section of ALA-2 (1,465 acres). STC-1 is located in the near and far east hills of the study area, from the northern border of the study area south to Anderson Reservoir. STC-2 is adjacent to STC-1 in the north and continues south to the southern and eastern boundaries of the study area. The study area supports 150,962 acres of critical habitat, including 2,964 acres of primary habitat and 146,452 acres of secondary habitat (**Table 4-9**). These critical habitat units include both breeding and upland habitats and account for 9% of the designated critical habitat for this species throughout the species' range.

The three primary constituent elements for California red-legged frog are:

1. *Aquatic Breeding Habitat*. Standing bodies of fresh water (with salinities less than 4.5 ppt), including natural and manmade (e.g., stock) ponds, slow-moving streams or pools within streams, and other ephemeral or permanent

water bodies that typically become inundated during winter rains and hold water for a minimum of 20 weeks in all but the driest of years.

2. *Aquatic Non-Breeding Habitat.* Freshwater pond and stream habitats, as described above, that may not hold water long enough for the species to complete its aquatic life cycle but which provide for shelter, foraging, predator avoidance, and aquatic dispersal of juvenile and adult California red-legged frogs. Other wetland habitats considered to meet these criteria include, but are not limited to: plunge pools within intermittent creeks, seeps, quiet water refugia within streams during high water flows, and springs of sufficient flow to withstand short-term dry periods.
3. *Upland Habitat.* Upland areas adjacent to or surrounding breeding and non-breeding aquatic and riparian habitat up to a distance of 1 mile (1.6 km) in most cases (i.e., depending on surrounding landscape and dispersal barriers) including various vegetation types such as grassland, woodland, forest, wetland, or riparian areas that provide shelter, forage, and predator avoidance for the California red-legged frog.

Impact of covered activity implementation on critical habitat units may occur as a result of rural development, park maintenance and new construction activities, and Plan implementation. There is some potential for impacts due to ongoing operations and maintenance activities, particularly in streams, to affect these two units, but permanent changes in land use are anticipated to be minimal. Avoidance and minimization measures described in Chapter 6 will reduce the potential for indirect impacts on critical habitat.

No more than 1,035 acres (less than 1%) of all California red-legged frog critical habitat in the study area will be affected by covered activities in this Plan (**Table 4-9**). The impact analysis does not identify impacts by critical habitat unit; rather, it identifies impacts grouped by all critical habitat present in the study area. However, 99% of all California red-legged frog critical habitat was also mapped as primary or secondary habitat for this Plan. Impacts to primary and secondary habitat are quantified and discussed in Section 4.6.2 *California Tiger Salamander, California Red-legged Frog, Western Pond Turtle*. In addition, **Table 5-21** also describes estimated acreages of California red-legged frog critical habitat that will be preserved within the Reserve System by unit.

## 4.8 Cumulative Effects

As described above, the impacts of covered activities were assessed in the context of existing conditions in the study area. Some activities and projects that are outside the scope of this Plan may nonetheless contribute to cumulative impacts on covered species. An analysis of cumulative effects is not required in an HCP or NCCP. However, we include an analysis here to support the federal Biological Opinion that will conclude the USFWS Section 7 internal consultation process (see Chapter 1 for details). The scope of the cumulative analysis in a Biological Opinion is limited to non-federal actions because federal actions (i.e., any federal project, project with federal funding, or project that requires a federal

permit) will be the subject of future Section 7 consultations in which cumulative impacts can be considered more fully. To support this analysis, the cumulative projects evaluated in this section are limited to non-federal projects that are not covered by the Plan. The EIR/EIS presents a thorough analysis of the cumulative effects of all projects, federal and non-federal, when combined with the effects of the Habitat Plan.

### 4.8.1 Future Potential Development by the City of Gilroy

The Gilroy General Plan (City of Gilroy 2002) designates a number of areas outside the 20-year planning boundary as future areas for development and open space (W. Faus pers. comm.). Policy 2.11 of the Gilroy General Plan designates two areas outside its 20-year planning boundary (the boundary used as the planning limit of urban growth for the purposes of this Plan) as potential areas for future development. These areas are described below.

- The area north of Day Road, west of Santa Teresa Boulevard, and east of the foothills. This area is suitable for long-term residential expansion and related development.
- The area east of U.S. 101 between Buena Vista and Masten Avenue, bordering on the highway. This area is suitable for long-term expansion of highway-oriented commercial development.

Other City policies place further restrictions on where future development may occur. Gilroy General Plan Policy 1.03 states that uses east of U.S. 101 are restricted to industrial and agricultural use except for (1) commercial developments with the majority of the customer base from outside Gilroy, and (2) public and quasi-public facilities. Residential care facilities that meet criteria of Policy 14.05, *Residential Care Facilities for Seniors*, will also be allowed east of U.S. 101. Future development is also identified for the area north of Day Road and west of Santa Teresa Boulevard, east of the foothills, which is an area suitable for long-term residential expansion and related development.

Policy 20.05 designates protected open space areas in conjunction with agricultural lands to create natural buffers, or “greenbelts,” between Gilroy and surrounding communities; in particular, between Gilroy and San Martin to the north. The policy states that if an adequate greenbelt cannot be established in the area north of Masten and Fitzgerald Roads, then the Gilroy land use designations should be amended to include a greenbelt strip in the northern part of Gilroy’s 20-year Planning Area. Masten and Fitzgerald Roads make up the northern boundary of Gilroy’s 20-year plan (the planning limit of urban growth for this Plan) as well as the southern boundary of the unincorporated community of San Martin. Both the requirements of a greenbelt along Masten and Fitzgerald Roads and the proximity to San Martin would greatly reduce the possibility of Gilroy expanding farther than the 20-year planning boundary to the north except as identified in the first bullet above.

Policy 25.01 restricts development in areas where potential danger to the health, safety, and welfare of residents exists unless it can be mitigated to an “acceptable level of risk.” This applies to development in areas subject to flood damage or geological hazard due to location and/or design. Policy 4.06 works together with policy 25.01 to encourage existing agricultural lands in areas subject to natural hazards, such as major flooding or soils with a high water table, to remain in long-term agricultural production where such use exists. Much of the land to the east of Llagas Creek and south of Gilroy falls into this category of potentially hazardous areas. While development is not prohibited in these areas, a great deal of work on existing flood management infrastructure may be required in advance of any further development in these areas.

Permanent and temporary, direct and indirect impacts to Plan covered species could occur as a result of expansion of urban development outside of the planning limits of urban growth for the City of Gilroy. These impacts would be similar to those impacts described above as occurring within the planning limit of urban growth or nearby to Gilroy, but would increase the extent of described impacts beyond that anticipated by this Plan. Species most likely to be affected by the expansion of Gilroy include species that use agricultural and riparian land cover types on the valley floor. This may include California red-legged frog, California tiger salamander, western pond turtle, western burrowing owl, least Bell’s vireo, tricolored blackbird, and San Joaquin kit fox (**Table 3-5**). The only plant covered species that may be affected is Loma Prieta hoita (**Table 3-6**).

## 4.8.2 Ongoing and Routine Agriculture

Ongoing and routine agricultural activities in the study area are not covered by this Plan except for pond maintenance as described in Chapter 2 if project proponents obtain a permit with the local jurisdiction and those activities eligible for and enrolled in the Neighboring Landowner Assurances Program (see Chapter 10, Section 10.2.7 *Assurances for Private Landowners*, for details of this program and what is covered). Under Section 4(d) of the ESA, routine ranching activities located on private or Tribal lands are exempt from the take prohibitions of Section 9 of the ESA (50 CFR 17.43). This exemption applies to both California red-legged frog and California tiger salamander. However, this exemption does not apply to cultivated agriculture. While it is anticipated that the effects of ongoing agricultural activities on covered species will be relatively low, there is the potential for cumulative effects on covered species to accrue. Ongoing ranching operations such as road construction, road maintenance, or intensive livestock grazing may limit or degrade habitat for species such as western pond turtle, California tiger salamander, California red-legged frog, and foothill yellow-legged frog. (However, ranching activities such as pond maintenance and moderate livestock grazing are essential to the long-term survival of some covered species such as California red-legged frog and California tiger salamander.) Rodent control on grazing lands may adversely affect western burrowing owl and California tiger salamander. Pesticide run-off could also reduce water quality. Some ongoing cultivated agricultural activities may limit or degrade foraging habitat for tricolored blackbird and western

burrowing owl. Covered species could be trampled by cattle, and hydrology of an area may also be impacted by a loss of or change to agricultural practices, specifically grazing practices (Pyke and Marty 2005).

### 4.8.3 Use of Existing Roads

As described above, the construction of rural roads, driveways, and access roads covered by this Plan is expected to increase mortality of covered species such as California red-legged frog and California tiger salamander. Continued use of existing rural roads (i.e., those not covered by the Plan) will contribute to a cumulative impact on these species through continued mortality and injury. The magnitude of this cumulative impact is unknown.

### 4.8.4 Landfill or Quarries

Landfills and quarries other than those described in this Plan are not covered activities under this Plan. If such projects are implemented, they would result in the loss of land cover at the site of the project. Due to urban development constraints and siting requirements for such projects, it is likely that construction of a landfill or quarry project would occur outside the valley floor where natural land covers are dominant. The substantial loss of natural land covers would likely affect the covered species of this Plan. At this time, no landfills or quarries other than those described in this Plan are anticipated to be developed in the study area. As such, possible cumulative impacts are unknown.

Permanent and temporary, direct and indirect impacts to Plan covered species could occur as a result of development of landfills or quarries within the study area. Due to the lack of information about where these projects could occur, it is difficult to describe the land cover-types or covered species that may be affected. Any additional loss of un-developed land cover would likely result in direct and indirect impacts to covered species in accordance with **Table 3-5** and **Table 3-6**.

**Table 4-1.** Potential Indirect Adverse Impacts on Covered Species from New Urban and Rural Development and Operation of the Habitat Plan Reserve System

	Lights in New Urban and Rural Areas	Harassment, Disturbance from More People	Harassment or Injury from Additional Pets	More Noise	Increased Vehicle-Related Disturbance and Mortality <sup>1</sup>	Spread of Invasive Exotic Plants or Wildlife	Increased Risk of Wildfire <sup>2</sup>	Increased Runoff of Urban Pollutants/Change in Hydrology	Increased Recreation in Reserves	Enhancement or Restoration Activities <sup>3</sup>	Habitat Plan Monitoring

**Table 4-1. Continued**

Lights in New Urban and Rural Areas	Harassment, Disturbance from More People	Harassment or Injury from Additional Pets	More Noise	Increased Vehicle-Related Disturbance and Mortality <sup>1</sup>	Spread of Invasive Exotic Plants or Wildlife	Increased Risk of Wildfire <sup>2</sup>	Increased Runoff of Urban Pollutants/Change in Hydrology	Increased Recreation in Reserves	Enhancement or Restoration Activities <sup>3</sup>	Habitat Plan Monitoring
-------------------------------------	--	---	------------	--	--	---	--	----------------------------------	--	-------------------------

Notes:

- <sup>1</sup> Excludes indirect effects of vehicle emissions, which causes the spread of invasive exotic plants on serpentine grassland.
- <sup>2</sup> Accounts for the increased risk of wildfire from a growing human population and increased access to wildfire-prone areas (i.e., the Reserve System), all of which is expected to increase the frequency of human-caused wildfire ignition. Effects of wildfires and firefighting activities would be direct, including grading, clearing, disking, mowing, irrigation and other fire suppression activities, plus the temporary damage done by the wildfire itself. In some cases, wildfire will be beneficial to many covered species.
- <sup>3</sup> Adverse impacts from restoration activities on covered species are expected to be temporary; long-term effects of restoration and enhancement will be beneficial.
- <sup>4</sup> Impacts from increased runoff of urban development downstream of urban development would be confined to streams and channels and would not likely affect terrestrial covered species.
- <sup>5</sup> Potential impacts if recreational users go off-trail.

Secondary Habitat	85	0	0%	0	<1%
Total	14,362	550	4%	92	<1%

## Notes:

<sup>1</sup> Includes species for which habitat distribution models were developed. For other covered species, see the text.

<sup>2</sup> Habitat as shown in Appendix D habitat distribution models.

<sup>3</sup> Allowable impacts to Bay checkerspot butterfly, fragrant fritillary, smooth lessingia, Metcalf Canyon jewelflower, and most beautiful jewelflower are capped below the estimated impacts to account for the caps on serpentine grassland (see Table 4-2) and Bay checkerspot butterfly habitat. These acreages are caps, not estimates.

<sup>4</sup> This cap does not apply to Bay checkerspot butterfly habitat units mapped as “historic/unoccupied” and “occupancy unknown.”

<sup>5</sup> Western burrowing owl modeled habitat includes occupied and potential nesting habitat only in the study area.

**Table 4-5a. In-Stream Capital Improvement Project Permanent Impact Estimation Methods and Key Assumptions**

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>San José<sup>4</sup></b>		
New and existing bridge (re)construction	<ul style="list-style-type: none"> <li>Determine total acres of expanded area on existing bridges</li> <li>Determine total acres of new proposed bridges</li> <li>Combine acres of expanded bridge with acres of new bridge</li> <li>Distribute acres across the three riparian land covers in proportion to those land covers occurrence in San José city limits</li> <li>Estimate stream impacts by identifying the total new width (bridge dimension parallel to stream bed) of expanded and new bridges in feet</li> </ul>	<ul style="list-style-type: none"> <li>Impacts are based on list of bridges provided by City of San José that will be built or reconstructed within the permit term. This list included bridge width and length for each existing, expanded, and new proposed bridge</li> <li>The list of bridges for City of San José includes the bridges that are likely to receive funding for replacement and/or rehabilitation within the 50-year permit term (J. Hart pers. comm. b)</li> <li>New permanent impact to land cover and streams is assumed only for new or expanded areas, not total footprint of all bridges as permanent impacts are assumed to have already taken place for existing infrastructure</li> <li>This method likely over estimates riparian impacts as it assumes that all new bridge area will remove riparian vegetation. It is likely that some new bridge locations will not have existing riparian vegetation</li> <li>Stream impacts assume that new bridge width is directly related to linear stream ft and that stream length covered by new or expanded bridge is permanently impacted</li> </ul>
New trails	<ul style="list-style-type: none"> <li>Identify all proposed new trails in GIS layer</li> <li>In GIS, overlay trails on the land cover layer and apply a 16-foot buffer</li> <li>Exclude all land covers from the results except the riparian land covers as impacts to all other land cover are already assumed in the urban development impact analysis</li> <li>Estimate stream impacts using GIS to calculate the number of new stream crossings made by new trails</li> <li>Multiply number of new stream crossings by 16-foot width to determine total linear ft of stream impacted</li> </ul>	<ul style="list-style-type: none"> <li>Impacts are based on a GIS trails layer provided by City of San José</li> <li>Assume a width of 16 feet (12 feet for the trail and two 2-foot compact gravel shoulders) (J. Hart pers. comm. a)</li> <li>Assume 100% of impacts resulting from overlay are permanent</li> <li>Existing trails are not assumed to be widened if reconstructed during the permit term</li> <li>Stream crossings of trails assumed to be 16 feet wide</li> </ul>
Cherry Flat dam seismic safety retrofit, including borrow site(s)	<ul style="list-style-type: none"> <li>Develop footprint of project based on existing dam footprint from aerial photos</li> <li>Overlay footprint on land cover layer in GIS</li> <li>Assess impacts to land cover types, including streams</li> </ul>	<ul style="list-style-type: none"> <li>That borrow site(s) will be approximately scaled to the size of the reservoir and dam when compared to County Parks dams, reservoirs, and borrow site size</li> </ul>
<b>Morgan Hill<sup>4</sup></b>		
Bridge expansion	No impacts assessed	<ul style="list-style-type: none"> <li>No expansion of existing bridges is assumed and therefore no new permanent land cover or stream impacts are assumed</li> </ul>

**Table 4-5a. Continued**

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
New bridge construction	No impacts assessed	<ul style="list-style-type: none"> <li>No new vehicular bridge construction is assumed for Morgan Hill; pedestrian and trail bridge impacts are assumed under the New Trails covered activity</li> </ul>
New trails	<ul style="list-style-type: none"> <li>Identify trail bridges using GIS</li> <li>Apply a 15-foot buffer to each trail where it crosses the in-stream area</li> <li>Overlay the resulting buffered area on the land cover layer to determine impacts to riparian land covers and linear ft of stream</li> </ul>	<ul style="list-style-type: none"> <li>Impacts based on an AutoCAD file provided by City of Morgan Hill (S. Golden pers. comm.); AutoCAD files were imported into GIS</li> <li>It is assumed that all trails in the AutoCAD data are new trails</li> <li>Impacts are assumed to occur in the area encompassed by a 15-foot buffer (30-foot width) along all linear infrastructure identified in the AutoCAD files provided by Morgan Hill (City of Morgan Hill recommended a buffer of 10–20 feet and the middle value of 15 feet was used) (S. Golden pers. comm.)</li> </ul>
Storm drains	No impacts assessed	<ul style="list-style-type: none"> <li>No impacts to streams from implementation of storm drain infrastructure are assumed; All crossings will be jack and bore (beneath the streambed) (J. Behzad pers. comm.)</li> </ul>
<b>Gilroy<sup>4</sup></b>		
Bridge expansion	<ul style="list-style-type: none"> <li>Utilize data provided by the City of Gilroy to calculate the area of each expanded bridge</li> <li>Distribute acres of expanded bridge to riparian land cover types proportional to occurrence in Gilroy</li> <li>Add all bridge expansion widths together to calculate linear feet of stream impacts</li> </ul>	<ul style="list-style-type: none"> <li>Bridge count, including length and width for planned bridge widening, was provided by the City of Gilroy for planned and existing bridges (K. Abrams pers. comm.)</li> </ul>
New bridge construction	<ul style="list-style-type: none"> <li>Utilize data provided by the City of Gilroy to calculate the area of each new bridge</li> <li>Distribute acres of new bridge to riparian land cover types proportional to occurrence in Gilroy</li> <li>Add all new bridge widths together to calculate linear feet of stream impacts</li> </ul>	<ul style="list-style-type: none"> <li>Bridge count, including length and width for planned new bridges, was provided by the City of Gilroy for planned and existing bridges (K. Abrams pers. comm.)</li> </ul>
New trails	<ul style="list-style-type: none"> <li>Identify location of new trails using GIS</li> <li>Apply a 15-foot buffer the mapped facility boundary where it crosses the in-stream area</li> <li>Overlay the resulting buffered area on the land cover layer to determine impacts to riparian land covers and linear ft of stream</li> </ul>	<ul style="list-style-type: none"> <li>Impacts are based on AutoCAD files provided by Gilroy of current master plans for infrastructure development; AutoCAD files were imported into GIS</li> <li>Impacts are assumed to occur in the area encompassed by a 15-foot buffer (30-foot width) along all linear infrastructure identified in the AutoCAD files; this assumption is consistent with the assumptions used for Morgan Hill</li> </ul>

Table 4-5a. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
Sewer improvements	<ul style="list-style-type: none"> <li>Identify location of sewer improvements using GIS</li> <li>Apply a 15-foot buffer the mapped facility boundary where it crosses the in-stream area</li> <li>Overlay the resulting buffered area on the land cover layer to determine impacts to riparian land covers</li> </ul>	<ul style="list-style-type: none"> <li>Impact consideration is based on AutoCAD files provided by Gilroy of current master plans for infrastructure development; AutoCAD files were imported into GIS</li> <li>Sewer improvement projects are assumed to avoid streams and not result in permanent stream impacts; a small amount of riparian vegetation may be affected; this is consistent with the guidance provided in the Water Collaborative Guidelines and Standards</li> </ul>
New recycled water pipes	<ul style="list-style-type: none"> <li>Identify location of new recycled water pipes using GIS</li> <li>Apply a 15-foot buffer the mapped facility boundary where it crosses the in-stream area</li> <li>Overlay the resulting buffered area on the land cover layer to determine impacts to riparian land covers</li> </ul>	<ul style="list-style-type: none"> <li>Impact consideration is based on AutoCAD files provided by Gilroy of current Master Plans for infrastructure development; AutoCAD files were imported into GIS</li> <li>Recycled water pipe projects are assumed to avoid streams and not result in permanent stream impacts; a small amount of riparian vegetation may be affected; this is consistent with the guidance provided in the Water Collaborative Guidelines and Standards</li> </ul>
Water improvements	<ul style="list-style-type: none"> <li>Identify location of water improvements using GIS</li> <li>Apply a 15-foot buffer the mapped facility boundary where it crosses the in-stream area</li> <li>Overlay the resulting buffered area on the land cover layer to determine impacts to riparian land covers</li> </ul>	<ul style="list-style-type: none"> <li>Impact consideration is based on AutoCAD files provided by Gilroy of current Master Plans for infrastructure development; AutoCAD files were imported into GIS</li> <li>Water improvement projects are assumed to avoid streams and not result in permanent stream impacts; a small amount of riparian vegetation may be affected; this is consistent with the guidance provided in the Water Collaborative Guidelines and Standards</li> </ul>
<b>SCVWD</b>		
Dam Maintenance Program	<ul style="list-style-type: none"> <li>In GIS, overlay the Area of Routine Maintenance footprint on the land cover layer and assess acres of land cover impacted</li> <li>In GIS, overlay the Area of Routine Maintenance and the Area of Potential Effect on the land cover layer</li> <li>Assess acres of land cover within the Area of Potential Effect but outside of the Area of Routine Maintenance</li> <li>Take 15% of the acres identified in the above bullet, proportional to the occurrence of each land cover type identified</li> <li>Add the land cover identified in the first bullet to the land cover identified in the fourth bullet together to identify total impacts</li> </ul>	<ul style="list-style-type: none"> <li>GIS footprint of Dam Maintenance Program project extent was provided by SCVWD</li> <li>SCVWD Dam Maintenance Program GIS data identifies the zone in which 85% of all impacts are expected to occur (also called the <i>Area of Routine Maintenance</i>); this area is assumed to experience permanent impact</li> <li>The remaining 15% of impacts would occur within the Area of Potential Effect; the Area of Potential Effect includes the Area of Routine Maintenance but is somewhat larger than the Area of Routine Maintenance</li> <li>Although this is a maintenance program, implementation of the Dam Maintenance Program results in a permanent clearing of all vegetation from the dam face and surrounding areas; therefore, this is considered a permanent impact to land covers (excluding riverine/streams) and is assessed under In-stream CIP</li> <li>Streams are not assumed to be permanently impacted due to implementation of the Dam Maintenance Program</li> </ul>

**Table 4-5a.** Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
Dam safety retrofit footprint	<ul style="list-style-type: none"> <li>• Overlay GIS footprints of “Area A” on land cover layer AND on Dam Maintenance Program footprints</li> <li>• Assess acres of land cover impacted Area A excluding any areas that overlap with the Dam Maintenance Program footprints</li> <li>• Integrate stream impact lengths provided by SCVWD</li> </ul>	<ul style="list-style-type: none"> <li>• Because permanent impacts to land cover were fully assumed for the Dam Maintenance Program, additional impacts to land cover in this zone are not assessed under safety retrofit</li> <li>• SCVWD provided safety retrofit footprints for all dams; this data identifies the footprint of the new dam (Area A), and the area affected by construction impacts (Area B); these footprints assume worst case dam reconstruction of downstream embankment strengthening</li> <li>• All land cover types, including streams, falling within the footprint are assumed to be lost</li> <li>• SCVWD provided stream impact numbers</li> <li>• Safety retrofit of Coyote, Chesbro, and Uvas Dams is not a covered activity under this Plan</li> </ul>
Safety retrofit borrow sites	<ul style="list-style-type: none"> <li>• Use the total acres of borrow site impacts as calculated in the draft Three Creeks HCP (April 2009) for Anderson, Almaden, Calero, and Guadalupe dam borrow sites</li> <li>• Identify the acres of each land cover type present within a 5-mile radius of each of the four dams</li> <li>• For each dam, distribute the total acres of borrow site impact proportionally across the land cover types within a 5-mile radius of the dam</li> </ul>	<ul style="list-style-type: none"> <li>• Acres required for safety retrofits covered by the draft Three Creeks HCP (April 2009) were used as the basis of this analysis</li> <li>• That borrow will be acquired within a 5 mile radius of the dam</li> <li>• This analysis does not account for avoidance of certain land cover types based on the siting criteria in Chapter 2; impacts to certain land cover types may be overestimated while others are underestimated</li> </ul>
Temporary supplemental water supply systems during reservoir drawdown	No impacts assessed	<ul style="list-style-type: none"> <li>• That impacts associated with this activity will be entirely contained within the footprints of the Dam Maintenance Program, the water utility / water supply operations and maintenance impacts, or within existing roads and other disturbed areas</li> </ul>
Water utility / water supply operation and maintenance	<ul style="list-style-type: none"> <li>• Determine permanent impacts as defined in the draft Three Creeks HCP (April 2009) impact analysis for the Coyote and Guadalupe watersheds (Stevens Creek numbers were excluded)</li> <li>• Divide this number by the number of dams in the study area in north County (six dams)</li> <li>• Multiply this number by the number of dams in south County (2 dams)</li> <li>• Distribute 0.4 acre of permanent impact to land cover types proportional to impact for other impacts in this activity</li> </ul>	<ul style="list-style-type: none"> <li>• The draft Three Creeks HCP (April 2009) identifies permanent impacts for operations and maintenance activities in the north County; these impacts were used for this Plan directly for north County impacts and indirectly to derive estimates for impacts associated with activities in south County</li> <li>• In addition to these estimates, some new access roads and facility pads may be required; assume up to 1,600 sq ft per new facility and up to 10 new facilities (0.4 acre); distribute impacts to land cover types proportional to other impacts in this category</li> <li>• That impacts in south County are proportional to impacts in north County based on the number of dams</li> </ul>

Table 4-5a. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
Lower Llagas vegetation management	<ul style="list-style-type: none"> <li>Using an aerial map for guidance, draw a polygon in GIS around the full extent of the project area including the outer edge of the channel levee as appropriate</li> <li>Overlay GIS polygon on land cover layer</li> <li>Assess total acres of land cover and streams impacted</li> <li>Reduce impacts by 50% for each land cover type</li> <li>Reduce impacts by 95% for permanent stream impacts</li> </ul>	<ul style="list-style-type: none"> <li>50% of existing vegetation will be removed and this reach permanently maintained in this state for flood protection purposes, resulting in a 50% permanent impact</li> <li>The stream may experience some degradation to habitat due to removal of large woody debris and other in-channel vegetation due to flood protection management needs; this amount of degradation is estimated as a permanent impact to 5% of the total stream length</li> </ul>
Canal reconstruction or realignment	<ul style="list-style-type: none"> <li>Using an aerial map for guidance, draw a polygon around the extent of each canal including access roads adjacent to the canal</li> <li>Overlay GIS polygons on land cover layer</li> <li>Assess total acres of land cover impacted</li> </ul>	<ul style="list-style-type: none"> <li>Canals will be dry when they are reconstructed and no stream impacts are anticipated</li> <li>Decommissioning of canals would result in reduced permanent impacts compared to reconstruction or realignment; this analysis assumes the highest level of impacts as associated with reconstruction or realignment</li> </ul>
Flood protection projects (collective)	<ul style="list-style-type: none"> <li>Using an aerial map for guidance, draw a polygon in GIS around the full extent of the project area including the outer edge of the channel levee as appropriate</li> <li>Overlay GIS polygon on land cover layer</li> <li>Assess total acres of land cover and streams impacted</li> <li>Reduce impacts by 80% for each land cover type</li> <li>Reduce impacts by 95% for permanent stream impacts</li> <li>Reduce final impacts by approximately one-third to account for cap on total flood protection projects covered by the Plan</li> </ul>	<ul style="list-style-type: none"> <li>That 20% of existing vegetation, on average, will be removed and permanently due to construction of flood control projects; this assumption is based on engineer drawings from past and current projects, and SCVWD professional experience in implementing flood control projects; this assumption is also based on implementation of the Clean, Safe, Creeks Program by which SCVWD protects and maintains as much natural structure of a stream system as possible</li> <li>Project footprint impacts were based on a polygon footprint from the outer edge of the existing channel or levee</li> <li>Total length of flood protection projects covered by the Plan is capped at 64 miles, with a maximum of 3.1 miles of permanent stream impacts</li> <li>The assumption that only 5% of the total stream length will be permanently impacts is based on: <ul style="list-style-type: none"> <li>review of past and planned projects;</li> <li>the understanding that SCVWD is committed to designing flood control projects to incorporate and support natural stream function and riparian habitat;</li> <li>development and adoption of the Clean, Safe Creeks and Natural Flood Protection Plan program to support the above commitment;</li> <li>examples of planned flood control projects that seek to remove existing development and replace it with a wider and more natural channel (Upper Penitencia project) and that may result in net benefit for habitat; and</li> <li>the understanding that conditions identified in the Habitat Plan (Condition 4) will be utilized and incorporated into project design and</li> </ul> </li> </ul>

Table 4-5a. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
		construction o Feedback from SCVWD engineers (D. Arnold pers. comm. a)
Levee reconstruction projects (collective)	<ul style="list-style-type: none"> <li>Using an aerial map for guidance, draw a polygon in GIS around the full extent of each individual levee (i.e., a channel with a levee on each side would require two separate polygons) including the outer edge of the channel levee as appropriate</li> <li>Import GIS levee layer and combine with levees mapped from the aerial photo</li> <li>Overlay GIS polygons on land cover layer</li> <li>Assess total acres of land cover impacted</li> <li>Reduce impacts by 95% for permanent stream impacts</li> <li>Divide all resulting impacts (land cover and stream) by one-half to account for 10 mile impact cap</li> </ul>	<ul style="list-style-type: none"> <li>Includes all reconstruction activities including improvements and expanded levees (taller or wider levees)</li> <li>SCVWD provided aerial images marking the extent of levee location (D. Arnold pers. comm. b); SCVWD also provided a GIS layer for SCVWD levees; levees identified in both data sources were utilized for this analysis</li> <li>Assumes levees will be reconstructed within the same footprint as in aerial photos and in GIS; may be a slight under estimation of impacts if levee encroaches into stream bed area due to design constraints</li> <li>Assumes that all vegetation within the footprint will be removed; may be an overestimate as levee reconstruction will not result in a loss of shaded riverine habitat</li> <li>Assumes impacts are capped at 10 miles</li> </ul>
Groundwater recharge ponds	<ul style="list-style-type: none"> <li>Digitize recharge ponds, new diversion dam at Metcalf Road, pipeline to Ford Road pond, and existing diversion outtake at Church Avenue in GIS</li> <li>Overlay GIS polygons on land cover layer</li> <li>Assess total acres of land cover impacted</li> <li>Delete impacts to “ponds” land cover type</li> </ul>	<ul style="list-style-type: none"> <li>SCVWD plans to re-operate Ford Road and Church Avenue groundwater recharge ponds; projects includes rehabilitation of diversion at Church Avenue and construction of a new diversion at Metcalf Road</li> <li>Ford Road project includes installation of a new pipeline from the diversion to the pond</li> <li>SCVWD provided aerial maps showing where the re-operated ponds are located</li> <li>Metcalf Road diversion is assumed to be approximately 200 feet (stream length) by 170 feet (stream width); and that approximately half of this area is riparian vegetation (0.4 acre of riparian)</li> <li>Approximately 80% of the Church Avenue ponds site is currently mapped as ponds land cover type; because ponds will be the land cover type after project implementation, impacts to the ponds land cover type were not included in the impact analysis</li> <li>As SCVWD’s water rights have not changed, no impact to in-stream flow is anticipated</li> </ul>
Alamitos Creek/Almaden Reservoir Fish Passage	<ul style="list-style-type: none"> <li>Digitize in GIS the general area of where the project components may go</li> <li>Distribute 30 acres of impacts proportional to the percentages of land cover in the generally mapped area</li> <li>Assess 50 feet of stream impact</li> </ul>	<ul style="list-style-type: none"> <li>Assume up to 30 acres of impact to land cover types around Almaden Dam and Reservoir</li> <li>Assume up to 50 feet of permanent stream loss</li> </ul>

Table 4-5a. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
Trails	No impacts assessed	<ul style="list-style-type: none"> <li>Assumes that trail projects are located on existing maintenance roads or as components of flood protection projects; therefore, impacts are assumed to either already have occurred (existing maintenance roads) or that impacts are captured by the impacts assessed for flood protection projects; no additional impacts to land cover are assessed</li> </ul>
<b>County Roads and Airports</b>		
Bridge replacement - expanded footprint	<ul style="list-style-type: none"> <li>Determine total acres of expanded area on existing bridges or acres of new bridges</li> <li>Distribute acres across the three riparian land covers in proportion to those land covers occurrence in the county</li> <li>Estimate stream impacts by identifying the total new width (bridge dimension parallel to stream bed) of expanded and new bridges in feet</li> </ul>	<ul style="list-style-type: none"> <li>Impacts based on data provided by County of Santa Clara Road and Airports containing a list of bridges that will be reconstructed within the permit term; This list includes bridge width and length for each existing bridge (D. Cameron pers. comm. a)</li> <li>County Roads has identified three road connection projects in the study area. One of these projects, Center Avenue extension to Marcella will require a new bridge. Another project, McKean Road connection to Almaden Expressway, may require a new bridge depending on land acquisition constraints (D. Cameron pers. comm. b)</li> <li>Aside from the exceptions noted in the above bullet, County Roads has no plans to build bridges in new locations in the Study area. Any new bridges would be due to land use development and would have to be funded by the developer and impacts are assessed under Rural Development</li> <li>Bridges are assumed to be double in width during reconstruction to account for new safety and seismic codes</li> <li>New permanent impact to land cover and streams is assumed only for new or expanded areas, not total footprint of all bridges as permanent impacts are assumed to have already taken place for existing infrastructure</li> <li>This method likely over estimates riparian impacts as it assumes that all new bridge area will remove riparian vegetation. It is likely that some new bridge locations will not have existing riparian vegetation</li> <li>Stream impacts assume that new bridge width is directly related to linear stream ft and that stream length covered by new or expanded bridge is permanently impacted</li> </ul>

Table 4-5a. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>County Parks</b>		
New bridges	<ul style="list-style-type: none"> <li>Calculate the stream miles of existing bridges (i.e., total width of all bridges)</li> <li>Calculate the ratio of existing but unplanned parks to existing but planned and constructed parks</li> <li>Multiple the miles of existing bridges by the ratio calculated in the previous bullet to determine miles of bridges in existing but unplanned parks</li> <li>Calculate the ratio of future park lands to existing park lands</li> <li>Multiple the miles of existing bridges by the ratio calculated in the previous bullet to determine miles of bridges in future parks</li> <li>Add the results of 3<sup>rd</sup> and 5<sup>th</sup> bullets for total new permanent stream impacts</li> </ul>	<ul style="list-style-type: none"> <li>The number of bridges constructed in the future is proportional to the number of bridges currently in existence</li> <li>Analysis only accounts for stream impacts as all other impacts are assessed under Rural CIP</li> </ul>
Dam safety retrofit, including borrow sites	<ul style="list-style-type: none"> <li>Using data provided by County Parks, develop polygons in GIS around dams</li> <li>Overlay on land cover layer to assess impacts to land cover type from dam retrofits</li> <li>Apply acres of impact for borrow sites to California annual grassland land cover type</li> </ul>	<ul style="list-style-type: none"> <li>County Parks provided impact numbers for the dam at Sandywool Lake and the five dams at Grant Lake and for the size of borrow pits required for each dam (D. Rocha pers. comm.)</li> <li>Borrow sites will be located in grasslands</li> </ul>
<b>VTA</b>		
Light-rail bridge reconstruction	<ul style="list-style-type: none"> <li>No impacts assessed</li> </ul>	<ul style="list-style-type: none"> <li>VTA provided a list of eight (8) light rail bridges that are likely to be replaced over the permit term</li> <li>New permanent impact to land cover and streams is assumed only for new or expanded areas, not total footprint as permanent impacts are assumed to have already taken place for existing infrastructure</li> <li>No expansion is assumed for reconstruction of VTA bridges</li> </ul>
S.R. 237 HOV /HOT lane (full length inside the study area)	<ul style="list-style-type: none"> <li>Use GIS to identify number of stream crossings</li> <li>Using aerial photos, identify length and width of existing stream crossings</li> <li>Add 24 ft to width of crossing (linear ft of stream)</li> <li>Convert to acres and apply impacts to the riparian land cover types proportional to how those land cover types exist within the planning limit of urban growth for the City of San José</li> <li>Assess permanent impacts to streams at 24 feet per crossing</li> </ul>	<ul style="list-style-type: none"> <li>VTA provided project location</li> <li>Full length of project is inside the planning limit of urban growth; no new land cover impacts are assumed because this area was assessed under the Urban Development impact category, with the exception of stream crossings</li> <li>Each stream crossing will require bridge widening of 24 feet</li> <li>New bridge width will affect in-stream riparian and linear feet of stream</li> </ul>

Table 4-5a. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
S.R. 85 HOV/HOT lane (full length inside the study area)	<ul style="list-style-type: none"> <li>• Use GIS to identify number of stream crossings</li> <li>• Using aerial photos, identify length and width of existing stream crossings</li> <li>• Add 24 feet to width of crossing (linear ft of stream)</li> <li>• Convert to acres and apply impacts to the riparian land cover types proportional to how those land cover types exist within the planning limit of urban growth for the City of San José</li> <li>• Assess permanent impacts to streams at 24 feet per crossing</li> </ul>	<ul style="list-style-type: none"> <li>• VTA provided project location</li> <li>• Full length of project is inside the planning limit of urban growth; no new land cover impacts are assumed because this area was assessed under the Urban Development impact category, with the exception of stream crossings</li> <li>• Each stream crossing will require bridge widening of 24 feet</li> <li>• New bridge width will affect in-stream riparian and linear feet of stream</li> </ul>

<sup>1</sup> All impact analyses are based on the baseline land cover as described in Chapter 4. Additional land cover parameters are identified in the Key Assumptions column.

<sup>2</sup> Unless otherwise noted, impacts to Urban-suburban, developed agriculture, landfill, and reservoir were excluded from final impact numbers because these land covers are assumed to either not provide any habitat value or will not be impacted in such a manner as to require conservation or mitigation (for the reservoir land cover).

<sup>3</sup> When using the method of impact distribution proportional to land cover, it is assumed that a project is likely to impact land covers in the same proportion at which land covers exist in a given project area. This approach may skew impacts higher for sensitive land covers that can be avoided through application of conditions on covered activities, design, and project siting, and skew impacts lower for impacts to less sensitive land covers that may be utilized in favor of impacting more sensitive land covers. Nonetheless, this impact analysis was conducted assuming any land cover can be impacted so long as it is not protected or excluded for other reasons (identified in the baseline data description).

<sup>4</sup> Impacts assessed for cities under the In-Stream impacts category only include impacts to riparian and riverine land cover types as impacts to all other land covers for urban development are assumed under the Urban Development impact analysis assumptions.

**Note:** This table of impact analysis methods and key assumptions is not intended to be all inclusive of all covered activities. Rather, this table shows how impacts were calculated for covered activities that have impacts significant enough to be estimated. Minor activities described in Chapter 2 are covered under this Plan even though they may not appear in this table.

**Table 4-5b.** In-Stream Capital Improvement Project Construction Temporary Impact Estimation Methods and Key Assumptions

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>San José<sup>4</sup></b>		
New and existing bridge (re)construction	<ul style="list-style-type: none"> <li>• Determine the total length of all existing and planned bridges</li> <li>• Multiply the total length of all existing and planned bridges by a construction width of 30 ft (15 ft buffer<sup>5</sup> on each side of the bridge) to identify acres of temporary impact</li> <li>• Distribute acres across the three riparian land covers in proportion to those land covers occurrence in San José city limits</li> <li>• Estimate temporary stream impacts by multiplying a 30 ft width of temporary impacts per bridge by the number of bridges to be constructed or reconstructed</li> </ul>	<ul style="list-style-type: none"> <li>• Impacts are based on list of bridges provided by City of San José that will be built or reconstructed within the permit term. This list included bridge width and length for each existing, expanded, and new proposed bridge</li> <li>• The list of bridges for City of San José includes the bridges that are likely to receive funding for replacement and/or rehabilitation within the 50-year permit term (J. Hart pers. comm. b)</li> <li>• Length of bridges is assumed to be bank to bank, perpendicular to flow, and that construction impacts would occur along the full length of the bridge</li> <li>• Temporary construction impacts are assumed to occur within 15 ft upstream and downstream of the bridge crossing, for a total construction width of 30 ft along the linear stream</li> <li>• Temporary impacts are not assumed for the area under the bridge as that area is assumed to be already permanently impacted by existing bridges or by new or expanded bridges</li> <li>• This method likely over estimates riparian impacts as it assumes impacts will temporarily affect riparian vegetation. It is likely that some bridge locations will not have existing riparian vegetation</li> </ul>
New trails	<ul style="list-style-type: none"> <li>• In GIS, overlay trails on the land cover layer and apply a 4 ft buffer</li> <li>• Exclude all land covers from the results except the riparian land covers as impacts to all other land cover are already assumed in the urban development impact analysis</li> <li>• Estimate stream impacts using GIS to calculate the number of stream crossings (existing and new) by trails</li> <li>• Multiply number of new stream crossings by 8 ft width to determine total linear ft of stream impacted</li> </ul>	<ul style="list-style-type: none"> <li>• Impacts are based on a GIS trails layer provided by City of San José</li> <li>• Assume temporary construction impacts occur in a buffer of 4 ft along each trail (8 ft total width, one-half of trail footprint)</li> </ul>

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>VTa</b>		
Light-rail bridges	<ul style="list-style-type: none"> <li>Determine the total length of all existing bridges</li> <li>Multiply the total length of all existing bridges by a construction width of 30 ft (15 ft buffer on each side of the bridge) to identify acres of temporary impact</li> <li>Distribute acres across the three riparian land covers in proportion to those land covers occurrence in San José city limits</li> <li>Estimate temporary stream impacts by multiplying a 30 ft width of temporary impacts per bridge by the number of existing bridges</li> </ul>	<ul style="list-style-type: none"> <li>Impacts based on data provided by VTA regarding location of bridges assumed to be reconstructed over the permit term</li> <li>The average width of each bridge is assumed to be 100 ft and average length 143 ft; these numbers correspond to the average width and length of San José bridges; all VTA bridges are located in San José</li> <li>Temporary impacts are assumed to occur within 15 ft upstream and downstream of the bridge crossing, for a total construction width of 30 ft along the linear stream</li> <li>All eight bridges are located inside of the San José planning limit of urban growth; therefore, only riparian impacts are assessed as all other impacts are assessed under the Urban Development category</li> <li>This method likely over estimates riparian impacts as it assumes impacts will temporarily affect riparian vegetation. It is likely that some bridge locations will not have existing riparian vegetation</li> </ul>
S.R. 237 HOV/HOT lane (full length inside the study area)	<ul style="list-style-type: none"> <li>20 ft of linear stream temporary impact per stream crossing</li> <li>Multiply 20 ft by the length of each crossing as identified under the permanent impact calculations and convert to acres</li> <li>Convert to acres and apply impacts to the riparian land cover types proportional to how those land cover types exist within the planning limit of urban growth for the City of San José</li> </ul>	<ul style="list-style-type: none"> <li>All construction impacts are assumed to occur on the adjacent freeway or within the median that is being permanently impacted, with the exception of in-stream areas</li> <li>Assume a temporary stream impact buffer of 10 ft (20 ft total width) on either side of the crossing</li> <li>Assume a temporary riparian impact buffer of 10 ft (20 ft total width) on either side of the crossing</li> </ul>
S.R. 85 HOV /HOT lane (full length inside the study area)	<ul style="list-style-type: none"> <li>20 ft of linear stream temporary impact per stream crossing</li> <li>Multiply 20 ft by the length of each crossing as identified under the permanent impact calculations and convert to acres</li> <li>Convert to acres and apply impacts to the riparian land cover types proportional to how those land cover types exist within the planning limit of urban growth for the City of San José</li> </ul>	<ul style="list-style-type: none"> <li>All construction impacts are assumed to occur on the adjacent freeway or within the median that is being permanently impacted, with the exception of in-stream areas</li> <li>Assume a temporary stream impact buffer of 10 ft (20 ft total width) on either side of the crossing</li> <li>Assume a temporary riparian impact buffer of 10 ft (20 ft total width) on either side of the crossing</li> </ul>

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<sup>1</sup> All impact analyses are based on the baseline land cover as described in Chapter 4. Additional land cover parameters are identified in the Key Assumptions column.		
<sup>2</sup> Unless otherwise noted, impacts to Urban-suburban, developed agriculture, landfill, and reservoir were excluded from final impact numbers because these land covers are assumed to either not provide any habitat value or will not be impacted in such a manner as to require conservation or mitigation (for the reservoir land cover).		
<sup>3</sup> When using the method of impact distribution proportional to land cover, it is assumed that a project is likely to impact land covers in the same proportion at which land covers exist in a given project area. This approach may skew impacts higher for sensitive land covers that can be avoided through application of conditions on covered activities, design, and project siting, and skew impacts lower for impacts to less sensitive land covers that may be utilized in favor of impacting more sensitive land covers. Nonetheless, this impact analysis was conducted assuming any land cover can be impacted so long as it is not protected or excluded for other reasons (identified in the baseline data description).		
<sup>4</sup> Impacts assessed for cities under the In-Stream impacts category only include impacts to riparian and riverine land cover types as impacts to all other land covers for urban development are assumed under the Urban Development impact analysis assumptions.		
<sup>5</sup> Buffers described for temporary impacts identify the area immediately surrounding the footprint of the associated project where temporary impacts are assumed to occur. Temporary impact buffers are in addition to buffers assumed to represent the project footprint as described in Table 4-5a.		
<b>Note:</b> This table of impact analysis methods and key assumptions is not intended to be all inclusive of all covered activities. Rather, this table shows how impacts were calculated for covered activities that have impacts significant enough to be estimated. Minor activities described in Chapter 2 are covered under this Plan even though they may not appear in this table.		

**Table 4-5c.** In-Stream Operations and Maintenance Temporary Impact Estimation Methods and Key Assumptions

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>San José</b>		
New and existing bridge maintenance	<ul style="list-style-type: none"> <li>• Determine the total length of all existing and planned bridges</li> <li>• Multiply the total length of all existing and planned bridges by a maintenance width of 24 ft (12 ft buffer on each side of the bridge) and convert to acres to identify acres of temporary impact</li> <li>• Distribute acres across the three riparian land covers in proportion to those land covers occurrence in San José city limits</li> <li>• Estimate temporary stream impacts by multiplying the maintenance buffer zone (24 ft) by the number of bridges to be maintained</li> </ul>	<ul style="list-style-type: none"> <li>• Impacts are based on list of bridges provided by City of San José that will be built or reconstructed within the permit term. Canal Maintenance in Serpentine	No impacts assessed	<ul style="list-style-type: none"> <li>• No impacts are assumed for canal maintenance because full permanent impacts to canals are assumed under In-Stream CIP for canal reconstruction</li> </ul>
Ground-Disturbing, Winter work in Almaden-Calero	No impacts assessed	<ul style="list-style-type: none"> <li>• No impacts are assumed for winter work in Almaden-Calero canal because full permanent impacts to this canal are assumed under In-Stream CIP for canal reconstruction</li> </ul>
<b>County Roads and Airports</b>		
Bridge Maintenance	<ul style="list-style-type: none"> <li>• Determine the total length of all existing bridges</li> <li>• Multiply the total length of all existing and planned bridges by a maintenance width of 24 ft (12 ft buffer on each side of the bridge) and convert to acres to identify acres of temporary impact</li> <li>• Distribute acres across the three riparian land covers in proportion to those land covers occurrence in the County</li> <li>• Estimate temporary stream impacts by multiplying the maintenance buffer zone (24 ft) by the number of bridges to be maintained</li> </ul>	<ul style="list-style-type: none"> <li>• County Roads is assumed to have 91 bridges that will be maintained</li> <li>• Temporary land cover impacts from operations and maintenance are assumed to occur within a 12 ft buffer up and downstream of the bridge (24 ft width total)</li> <li>• Temporary impacts are not assumed for the area under the bridge as that area is assumed to be already permanently impacted by existing bridges or by new or expanded bridges</li> </ul>

Table 4-5c. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>County Parks</b>		
Bridge Maintenance	<ul style="list-style-type: none"> <li>• Determine the total length of all existing and planned bridges</li> <li>• Multiply the total length of all existing and planned bridges by a maintenance width of 24 ft (12 ft buffer on each side of the bridge) and convert to acres to identify acres of temporary impact</li> <li>• Distribute acres across the three riparian land covers in proportion to those land covers occurrence in the County</li> <li>• Estimate temporary stream impacts by multiplying the maintenance buffer zone (24 ft) by the number of bridges to be maintained</li> </ul>	<ul style="list-style-type: none"> <li>• Impacts based on data provided by County of Santa Clara Parks Department containing a list of existing bridges; this list includes bridge width and length for each existing bridge</li> <li>• County Roads is assumed to have 69 bridges, inclusive of vehicular and trail stream crossing</li> <li>• Temporary land cover impacts from operations and maintenance are assumed to occur within a 12 ft buffer up and downstream of the bridge (24 ft width total)</li> <li>• Temporary impacts are not assumed for the area under the bridge as that area is assumed to be already permanently impacted by existing bridges or by new or expanded bridges</li> </ul>
<b>VTA</b>		
Light-rail bridge Maintenance	<ul style="list-style-type: none"> <li>• Determine the total length of all bridges</li> <li>• Multiply the total length of all bridges by a maintenance width of 24 ft (12 ft buffer on each side of the bridge) and convert to acres to identify acres of temporary impact</li> <li>• Distribute acres across the three riparian land covers in proportion to those land covers occurrence in San José city limits</li> <li>• Estimate temporary stream impacts by multiplying the maintenance buffer zone (24 ft) by the number of bridges to be maintained</li> </ul>	<ul style="list-style-type: none"> <li>• Impacts based on data provided by VTA regarding location of bridges assumed to be reconstructed over the permit term</li> <li>• The average length is assumed to be 143 ft; this number corresponds to the average width and length of San José bridges; all VTA bridges are located in San José</li> <li>• Temporary land cover and stream impacts are assumed to occur within 12 ft upstream and downstream of the bridge crossing, for a total maintenance width of 24 ft along the linear stream; this assumption is based on County Roads maintenance buffers</li> <li>• Temporary impacts are not assumed for the area under the bridge as that area is assumed to be already permanently impacted by existing bridges</li> <li>• All eight bridges are located inside of the San José planning limit of urban growth; therefore, only riparian impacts are assessed as all other impacts are assessed under the Urban Development category</li> <li>• This method likely over estimates riparian impacts as it assumes impacts will temporarily affect riparian vegetation. It is likely that some bridge locations will not have existing riparian vegetation</li> </ul>

Table 4-5c. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>General</b>		
Natural resource protection (small bank stabilization projects, restoration to reduce erosion, fish passage enhancements, and debris)	<ul style="list-style-type: none"> <li>• For bank stabilization, multiply 10*50 feet*20 feet, convert to acres, and distribute this impact across riparian land-cover types in proportion to relative presence in the study area of the riparian land-cover types</li> <li>• For bank stabilization projects, multiply 10*50 feet, convert to miles of temporary steam impact</li> <li>• For erosion control projects, multiply 5*50 feet*50 feet, convert to acres, and distribute this impact across riparian land-cover types in proportion to relative presence in the study area of the riparian land-cover types</li> <li>• For erosion control projects, multiply 5*50 feet, convert to miles of temporary steam impact</li> <li>• For fish passage projects, multiply 2*50 feet*20 feet, convert to acres, and distribute this impact across riparian land-cover types in proportion to relative presence in the study area of the riparian land-cover types</li> <li>• For fish passage projects, multiply 2*50 feet, convert to miles of temporary steam impact</li> </ul>	<ul style="list-style-type: none"> <li>• Assume that Local Partners will request, on average, 10 bank stabilizations per year; each stabilization is 50 feet long and 20 feet wide; that this area will impact riparian vegetation; that one-half of the projects will require dewatering which results in a temporary stream impact</li> <li>• Assume that Local Partners will request, on average, 5 erosion correction projects per year; each project 50 feet long and 50 feet wide; that this area will impact riparian vegetation; that one-half of the projects will require dewatering which results in a temporary stream impact</li> <li>• Assume that Local Partners will request, on average, 2 fish passage enhancement projects per year; each project 50 feet long and 15 feet wide; that this area will impact riparian vegetation; that one-half of the projects will require dewatering which results in a temporary stream impact</li> <li>• Debris removal impacts are assumed to be too small to estimate</li> </ul>

<sup>1</sup> All impact analyses are based on the baseline land cover as described in Chapter 4. Additional land cover parameters are identified in the Key Assumptions column.

<sup>2</sup> Unless otherwise noted, impacts to Urban-suburban, developed agriculture, landfill, and reservoir were excluded from final impact numbers because these land covers are assumed to either not provide any habitat value or will not be impacted in such a manner as to require conservation or mitigation (for the reservoir land cover).

<sup>3</sup> When using the method of impact distribution proportional to land cover, it is assumed that a project is likely to impact land covers in the same proportion at which land covers exist in a given project area. This approach may skew impacts higher for sensitive land covers that can be avoided through application of conditions on covered activities, design, and project siting, and skew impacts lower for impacts to less sensitive land covers that may be utilized in favor of impacting more sensitive land covers. Nonetheless, this impact analysis was conducted assuming any land cover can be impacted so long as it is not protected or excluded for other reasons (identified in the baseline data description).

**Note:** This table of impact analysis methods and key assumptions is not intended to be all inclusive. Rather, this table shows how impacts were calculated for covered activities that have impacts significant enough to be estimated. Minor activities described in Chapter 2 are covered under this Plan even though they may not appear in this table.

**Table 4-5d. Rural Capital Improvement Project Permanent Impact Estimation Methods and Key Assumptions**

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1,2,3</sup>
<b>San José</b>		
Kirby Canyon Landfill expansion	<ul style="list-style-type: none"> <li>• Digitize in GIS the Kirby Canyon Landfill Fill Areas</li> <li>• Overlay digitized Fill Areas on the land cover layer</li> <li>• Assess impacts to land cover and to streams for Fill Areas 3 and 4</li> </ul>	<ul style="list-style-type: none"> <li>• The City of San José is seeking coverage under the Habitat Plan for development of Fill Areas 3 and 4</li> <li>• A digital aerial map of Kirby Canyon Landfill Fill Areas was provided that identified Fill Areas (T. Peterson pers. comm.)</li> </ul>
<b>Morgan Hill</b>		
Butterfield detention basin	<ul style="list-style-type: none"> <li>• Identify proposed Butterfield detention basin in GIS</li> <li>• Overlay footprint of detention basin on the land cover layer to determine land cover impacts</li> </ul>	<ul style="list-style-type: none"> <li>• Impacts based on an AutoCAD file provided by City of Morgan Hill (S. Golden pers. comm.); AutoCAD files were imported into GIS</li> <li>• No stream impacts are assumed</li> </ul>
<b>SCVWD</b>		
Llagas recharge basins #1, #2, and #3, and Coyote Greenbelt recharge basin	<ul style="list-style-type: none"> <li>• SCVWD provided approximate project locations for the three Llagas groundwater recharge basins, and for the approximate location of the Coyote Greenbelt groundwater recharge basin</li> <li>• Digitize in GIS the boundaries for the location of the Llagas recharge basins and the Coyote Greenbelt basin</li> <li>• These boundaries are larger than the actual project, but represent the general area in which the project will occur</li> <li>• Assess total acres of each project area including acres of project area that is located inside of a planning limit of urban growth</li> <li>• Assess acres of land cover inside of each project area and determine proportion of each land cover within each project area</li> <li>• Calculate total project footprint based on percentage of project area acres inside/outside of a planning limit of urban growth (e.g., project area #3 is 69% located in the County and 31% located in Morgan Hill's planning limit of urban growth; therefore, for a 10 acre project, only 69% of 10 acres would be counted in the impacts because the other 31% was already assessed under Urban Development impacts)</li> <li>• Distribute project impacts proportionally across the land covers identified to be located in each project area</li> <li>• Include an additional 2.2 acres of impacts, distributed to barren and agriculture land covers</li> </ul>	<ul style="list-style-type: none"> <li>• For the Llagas recharge basins, total project footprint for each project is 10 acres (for a total of 30 acres)</li> <li>• Portions of the Llagas recharge basin project area fall within the Morgan Hill planning limit of urban growth; all impacts for areas zoned for development were included in the Urban Development impact assessment; therefore, portions of projects that overlap with Morgan Hill are not assessed in this analysis</li> <li>• For the Coyote Greenbelt basin, total project footprint is 15 acres</li> <li>• Coyote Greenbelt project will occur in the Coyote Greenbelt in close proximity to the Cross Valley Pipeline</li> <li>• 1.5 miles of new access road are assumed to be gravel roads, 12 ft wide and located in disturbed barren or agriculture lands</li> <li>• No stream impacts are assumed as the projects are not located in a stream or in a riparian area</li> </ul>

Table 4-5d. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1,2,3</sup>
<b>County Roads and Airports</b>		
South County Airport Master Plan	<ul style="list-style-type: none"> <li>• Digitize in GIS the extent of the airport, excluding existing developed areas, aviation easements, and proposed fee simple acquisition areas</li> <li>• Calculate the acres of each land cover type within this area</li> <li>• Distribute project impacts identified by the County proportionally across the land covers identified GIS</li> </ul>	<ul style="list-style-type: none"> <li>• The South County Airport Master Plan was used to identify areas of impact; lands identified as proposed aviation easements and proposed fee simple acquisition were not included in the impact analysis as they are not assumed to be developed further than already exists (e.g., developed residences may be removed and replaced with agricultural uses)</li> <li>• The County provided acres of estimated impacts to be 11.5 acres associated with runway extension and 26 acres associated with new facilities (D. Cameron pers. comm. a)</li> <li>• No stream impacts are assumed</li> </ul>
South County Circulation Study intersection improvement projects	<ul style="list-style-type: none"> <li>• Based on data provided, identify intersection projects in GIS</li> <li>• Apply project footprint width and length in GIS</li> <li>• Overlay project footprint on land cover layer</li> <li>• Assess impacts to land cover</li> </ul>	<ul style="list-style-type: none"> <li>• County of Santa Clara provided a spreadsheet of road intersection projects identified in the South County Circulation Study that may be completed during the permit term (D. Cameron pers. comm. b)</li> <li>• Data provided included width of expansion by intersection; most projects include an expansion of 12 ft (6 ft buffer) along 300 ft of road in each direction from the center of the intersection; these widths were used to identify new permanent impacts for each project</li> <li>• Impacts were not assessed for projects, or portions of projects, that overlap with a planning limit of urban growth AND that occur outside of in-stream areas as these impacts are already assessed under the Urban Development assumptions</li> <li>• No new stream impacts are assumed as all intersection improvements are made to existing intersections and replacement of existing bridges is assessed under the In-Stream CIP category</li> </ul>

Table 4-5d. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1,2,3</sup>
South County Circulation Study road improvement projects	<ul style="list-style-type: none"> <li>• Based on data provided, identify project road segment in GIS</li> <li>• Apply project width to road line in GIS</li> <li>• Overlay resulting project footprint on land cover layer</li> <li>• Remove areas of overlap with South County Circulation Study Intersection Improvement Projects</li> <li>• Assess impacts to land cover</li> <li>• Identify number of stream crossings for each new road alignment by counting number of times the new road alignment crosses a stream</li> <li>• Multiply the number of crossings by 60 ft</li> </ul>	<ul style="list-style-type: none"> <li>• County of Santa Clara provided a spreadsheet of road projects identified in the South County Circulation Study that may be completed during the permit term (D. Cameron pers. comm. b)</li> <li>• Data provided included start and end points for each projects, and width of expansion or new road project; widths ranged from an additional 8 ft to 92 ft; these widths were used to identify new permanent impacts for each project</li> <li>• Impacts were not assessed for projects, or portions of projects, that overlap with a planning limit of urban growth, including projects that immediately border a planning limit of urban growth, AND that occur outside of in-stream areas as these impacts are already assessed under the Urban Development assumptions</li> <li>• Assume stream impacts only for new roads (impacts for replacement of existing roads is assessed under In-Stream CIP Construction category); Stream impacts were calculated based on number of crossings and the assumptions that each stream crossing was, on average, 60 ft</li> </ul>
County Roads safety projects and turn lanes	<ul style="list-style-type: none"> <li>• Multiply miles of safety and intersection projects by the appropriate width and convert to acres</li> <li>• Distribute 25 miles of safety projects and 0.5 mile of turning lane project impacts to land cover types proportional to those land cover type occurrences in the near and far east hill zones developed for the Rural Development analysis</li> <li>• Distribute 8 miles of safety projects and 1 mile of turning lane project impacts to land cover types proportional to those land cover type occurrences in the valley floor zone developed for the Rural Development analysis</li> </ul>	<ul style="list-style-type: none"> <li>• The County provided data for miles and width of safety and intersection projects, as well as general location of projects; 33 miles of safety projects, requiring 8 ft of new road, with 25 miles in the near east and west hills and the remainder on the valley floor; 1.5 miles of turn lanes requiring 12 ft of new road, with 0.5 miles in the near east and west hills and the remainder on the valley floor</li> <li>• No additional bridge expansions beyond those addressed in the road projects</li> </ul>

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1,2,3</sup>
<b>County Parks</b>		
New trails, fire roads, and development	<ul style="list-style-type: none"> <li>• Import County Parks covered activity impacts into the Plan's impact analysis</li> <li>• Reduce impacts by 25%</li> </ul>	<ul style="list-style-type: none"> <li>• County Parks conducted its own impact analysis and provided these impacts for inclusion in this Plan; this analysis evaluated all uses and impacts (recreational and natural resource management) anticipated to occur during the permit term and impacts associated with implementing the Plan's conservation strategy within County Parks lands</li> <li>• County Parks developed impact numbers and distributed impacts to land cover types based on existing land use in existing parks, components of master plans not yet implemented, and anticipated avoidance of certain land cover types</li> <li>• Assumptions for development outside of the planning limit of urban growth: 20 miles of fire road (12 ft wide); 25 miles of unpaved, single-track trail (5 ft wide); 3 miles of paved service roads (12 ft wide); 7 miles of paved multi-use trail (16 ft wide); and 10 miles of paved roads (20 ft wide); This does not include roads and trails that are part of a larger site development (e.g., nature center, large picnic areas, pavilions, golf course, etc.)</li> <li>• Assumptions for development outside of the planning limit of urban growth: larger-scale site development projects (e.g., nature center, large picnic areas, pavilions, golf course, etc.) requiring 1,700 acres</li> <li>• Assumptions for impacts to in-stream resources: 300 non-bridge water crossings (e.g., single-track trail crossings; 40 sq ft), 20 large bridges (i.e., one-or two-way automotive use; 924 sq ft), and 30 small bridges and puncheons (i.e., footbridges; 54 sq ft )</li> <li>• Assumption that County Parks will only implement approximately 75% of described projects</li> </ul>

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1,2,3</sup>
<b>VTA<sup>4</sup></b>		
U.S. 101 Improvement Project (Monterey Road to SR 129)	<ul style="list-style-type: none"> <li>• Acres of permanent impact by land cover type, including streams, provided by VTA were used to assess impacts</li> </ul>	<ul style="list-style-type: none"> <li>• This project includes extending Santa Teresa Boulevard from Castro Valley Road to US 101</li> <li>• This road extension requires a new bridge to be constructed across Gavilan Creek</li> <li>• VTA provided impact estimates for this project that were recently developed for the environmental compliance process for this project (A. Calnan pers. comm.); impacts included both permanent and temporary impacts</li> <li>• These impact estimates were used for both land cover and stream impacts</li> </ul>
U.S. 101 widening between Cochrane Rd. and Monterey Hwy	<ul style="list-style-type: none"> <li>• Identify project road segments in GIS</li> <li>• Apply a 50 ft buffer to the existing road line in GIS</li> <li>• Overlay on the land cover layer</li> <li>• Assess impacts to land cover</li> <li>• Identify number of stream crossings along the length of the project by counting number of times the project crosses a stream</li> <li>• Multiply the number of crossings by 100 ft to determine stream impacts</li> </ul>	<ul style="list-style-type: none"> <li>• Assume a buffer of 50 ft (100 ft width) on either side of the existing road line</li> <li>• Assume a stream impact width of 100 ft per stream crossing</li> <li>• A portions of this project fall within the Morgan Hill and Gilroy planning limits of urban growth</li> <li>• Areas inside the planning limit of urban growth AND outside of the in-stream areas were excluded from the analysis as impacts for these areas are assessed under urban development</li> <li>• Assume a stream impact width of 100 ft per stream crossing</li> </ul>
Buena Vista Interchange	No impacts assessed	<ul style="list-style-type: none"> <li>• The Buena Vista Interchange is located inside of the Gilroy planning limit of urban growth and does not overlap with any in-stream areas or stream channels; no additional impacts (beyond those assumed for areas inside planning limits of urban growth under urban development) are assumed for this project</li> </ul>
Caltrain Double Tracking	<ul style="list-style-type: none"> <li>• Identify project track segments in GIS</li> <li>• Apply a 50 ft buffer to the existing track line in GIS</li> <li>• Overlay on the land cover layer</li> <li>• Assess impacts to land cover</li> <li>• Identify number of stream crossings along the length of the project by counting number of times the project crosses a stream</li> <li>• Multiply the number of crossings by 100 ft</li> </ul>	<ul style="list-style-type: none"> <li>• Assume a buffer of 50 ft (100 ft width) on either side of the existing track line</li> <li>• Assume a stream impact width of 100 ft per stream crossing</li> </ul>

U.S. 101 HOV/HOT lane (Masten Avenue to 10th Street; VTA ID H7)	<ul style="list-style-type: none"> <li>• Using aerial photos, identify width of stream crossing</li> <li>• Assess impacts to streams consistent with the required width of the new bridge</li> </ul>	<ul style="list-style-type: none"> <li>• VTA provided project location</li> <li>• This project is located entirely within the planning limit of urban growth for Gilroy, the development of which is covered in the Urban Development category; no impacts are assessed aside from the stream crossing</li> <li>• One stream crossing will require a new bridge</li> <li>• No riparian impacts are assumed because aerial photos show this reach of stream is channelized and does not support any riparian vegetation</li> </ul>
U.S. 101 HOV/HOT lane (10th Street to SR 25; VTA ID H8)	<ul style="list-style-type: none"> <li>• Use GIS to map length of project</li> <li>• Multiply length of project by 32 (2 lanes plus 2 shoulders) and convert to acres of impact</li> <li>• Apply acres of impact to annual grassland land cover type</li> <li>• Using aerial photos, identify length and width of stream crossing</li> <li>• Convert to acres and apply impacts to the riparian land cover types proportional to how those land cover types exist in Gilroy</li> <li>• Assess impacts to streams consistent with the required width of the new bridge</li> </ul>	<ul style="list-style-type: none"> <li>• VTA provided project location</li> <li>• Assume 12 ft for a new HOV/HOT lane in each direction, plus 4 ft in each direction for additional shoulder</li> <li>• All impacts occur in the existing median</li> <li>• Median is categorized as annual grassland land cover type</li> <li>• Impacts inside the planning limit of urban growth are excluded because these area were assessed under the Urban Development impact category, with the exception of stream crossings</li> <li>• One stream crossing will require a new bridge</li> </ul>

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1,2,3</sup>
<sup>1</sup> All impact analyses are based on the baseline land cover as described in Chapter 4. Additional land cover parameters are identified in the Key Assumptions column.		
<sup>2</sup> Unless otherwise noted, impacts to Urban-suburban, developed agriculture, landfill, and reservoir were excluded from final impact numbers because these land covers are assumed to either not provide any habitat value or will not be impacted in such a manner as to require conservation or mitigation (for the reservoir land cover).		
<sup>3</sup> When using the method of impact distribution proportional to land cover, it is assumed that a project is likely to impact land covers in the same proportion at which land covers exist in a given project area. This approach may skew impacts higher for sensitive land covers that can be avoided through application of conditions on covered activities, design, and project siting, and skew impacts lower for impacts to less sensitive land covers that may be utilized in favor of impacting more sensitive land covers. Nonetheless, this impact analysis was conducted assuming any land cover can be impacted so long as it is not protected or excluded for other reasons (identified in the baseline data description).		
<sup>4</sup> All VTA projects are listed in Table 2-6.		
<b>Note:</b> This table of impact analysis methods and key assumptions is not intended to be all inclusive. Rather, this table shows how impacts were calculated for covered activities that have impacts significant enough to be estimated. Minor activities described in Chapter 2 are covered under this Plan even though they may not appear in this table.		

**Table 4-5e.** Rural Capital Improvement Project Construction Temporary Impact Estimation Methods and Key Assumptions

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1,2,3</sup>
<b>San José</b>		
Kirby Canyon Landfill Expansion	No impacts assessed	<ul style="list-style-type: none"> <li>Construction impacts are assumed to be included within the permanent impacts for Kirby Canyon landfill</li> </ul>
<b>Morgan Hill</b>		
Butterfield detention basin	<ul style="list-style-type: none"> <li>Identify proposed Butterfield detention basin in GIS</li> <li>Apply a 10 ft buffer around the project footprint</li> <li>Overlay the buffer on the land cover layer in GIS</li> <li>Assess temporary impacts to land cover</li> </ul>	<ul style="list-style-type: none"> <li>Impacts based on an AutoCAD file provided by City of Morgan Hill (S. Golden pers. comm.); AutoCAD files were imported into GIS</li> <li>Temporary construction impacts are assumed to occur within a 10 ft buffer around the project footprint</li> <li>No stream impacts are assumed</li> </ul>
<b>SCVWD</b>		
Llagas Recharge basins #1, #2, and #3, and Coyote Greenbelt Recharge basin	<ul style="list-style-type: none"> <li>Based on 10-acre or 15-acre square sites, identify the acres of construction and staging area within a 10 ft buffer of the project site</li> <li>Scale construction buffer impacts according to how much of the project area is located outside of a planning limit of urban growth</li> <li>Distribute construction buffer impacts proportionally across the land covers identified to be located in the project area (conducted a part of capital improvement project impact assessment)</li> </ul>	<ul style="list-style-type: none"> <li>Project areas will be approximately square</li> <li>Buffer of average distance outside of project area that will be impacted during construction is 10 ft</li> <li>1.5 miles of new access road are assumed to temporarily disturb 1 ft on either side of the road and will affect the same land-cover types as the permanent road footprint</li> <li>No stream impacts are assumed as the projects are not located in a stream or in a riparian area</li> </ul>
<b>County Roads and Airports</b>		
South County Airport Master Plan	<ul style="list-style-type: none"> <li>Multiply permanent land cover impacts for this project by 10%</li> </ul>	<ul style="list-style-type: none"> <li>Temporary construction impacts to land cover are assumed to be 10% of the total permanent impacts to land cover</li> <li>No stream impacts are assumed</li> </ul>
South County Circulation Study intersection improvement projects	<ul style="list-style-type: none"> <li>Based on data provided, identify intersection projects in GIS</li> <li>Apply 10 ft buffer to project footprint in GIS</li> <li>Overlay construction buffer on land cover layer</li> <li>Assess impacts to land cover</li> <li>Identify temporary stream impacts by multiplying the permanent stream impacts by one-third</li> </ul>	<ul style="list-style-type: none"> <li>County of Santa Clara provided a spreadsheet of road intersection projects identified in the South County Circulation Study that may be completed during the permit term (D. Cameron pers. comm.)</li> <li>Impacts were not assessed for projects, or portions of projects, that overlap with a planning limit of urban growth AND that occur outside of in-stream areas as these impacts are already assessed under the Urban Development assumptions</li> <li>Assume temporary impacts to land cover occur in a 10 ft buffer<sup>4</sup> around project footprints</li> <li>Assume temporary stream impacts occur within a 10 ft construction buffer (20 ft width); this is equal to one-third of permanent stream impacts</li> </ul>

Table 4-5e. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1,2,3</sup>
U.S. 101 HOV/HOT lane (western study area boundary to Cochrane Road)	<ul style="list-style-type: none"> <li>Convert to acres and apply impacts to the riparian land cover types proportional to how those land cover types exist within the City of San José or the valley floor rural development zone, depending on the location of the crossing</li> </ul>	<ul style="list-style-type: none"> <li>All construction impacts are assumed to occur on the adjacent freeway or within the median that is being permanently impacted, with the exception of in-stream areas</li> <li>Assume a temporary stream impact buffer of 10 ft (20 ft total width) on either side of the crossing</li> <li>Assume a temporary riparian impact buffer of 10 ft (20 ft total width) on either side of the crossing</li> </ul>
U.S. 101 HOV/HOT lanes (Cochrane Road to Masten Avenue; VTA ID H6)	<ul style="list-style-type: none"> <li>20 ft of linear stream temporary impact per stream crossing</li> <li>Multiply 20 ft by the length of each crossing as identified under the permanent impact calculations and convert to acres</li> <li>Convert to acres and apply impacts to the riparian land cover types</li> </ul>	<ul style="list-style-type: none"> <li>All construction impacts are assumed to occur on the adjacent freeway or within the median that is being permanently impacted with the exception of in-stream areas</li> <li>Assume a temporary stream impact buffer of 10 ft (20 ft total width) on either side of the crossing</li> <li>Assume a temporary riparian impact buffer of 10 ft (20 ft total width) on either side of the crossing</li> </ul>

<sup>1</sup> All impact analyses are based on the baseline land cover as described in Chapter 4. Additional land cover parameters are identified in the Key Assumptions column.

<sup>2</sup> Unless otherwise noted, impacts to Urban-suburban, developed agriculture, landfill, and reservoir were excluded from final impact numbers because these land covers are assumed to either not provide any habitat value or will not be impacted in such a manner as to require conservation or mitigation (for the reservoir land cover).

<sup>3</sup> When using the method of impact distribution proportional to land cover, it is assumed that a project is likely to impact land covers in the same proportion at which land covers exist in a given project area. This approach may skew impacts higher for sensitive land covers that can be avoided through application of conditions on covered activities, design, and project siting, and skew impacts lower for impacts to less sensitive land covers that may be utilized in favor of impacting more sensitive land covers. Nonetheless, this impact analysis was conducted assuming any land cover can be impacted so long as it is not protected or excluded for other reasons (identified in the baseline data description).

<sup>4</sup> Buffers described for temporary impacts identify the area immediately surrounding the footprint of the associated project where temporary impacts are assumed to occur. Temporary impact buffers are in addition to buffers assumed to represent the project footprint as described in Table 4-5d.

**Note:** This table of impact analysis methods and key assumptions is not intended to be all inclusive. Rather, this table shows how impacts were calculated for covered activities that have impacts significant enough to be estimated. Minor activities described in Chapter 2 are covered under this Plan even though they may not appear in this table.

**Table 4-5f. Rural Operations and Maintenance Temporary Impact Estimation Methods and Key Assumptions**

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>SCVWD</b>		
<i>Pipeline Maintenance Program</i>		<ul style="list-style-type: none"> <li>• All impacts assessed under the Pipeline Maintenance Program were derived from the Pipeline Maintenance Program EIR (Santa Clara Valley Water District 2006)</li> <li>• The Pipeline Maintenance Program covers SCVWD's activities throughout the County, not only in the Habitat Plan study area; therefore, impacts assessed here are slightly over estimated</li> <li>• The Pipeline Maintenance Program uses the term "aquatic" to describe impacts to acres of stream. This Plan assesses stream, or riverine, impacts linearly. For this analysis, acres of impact assessed for aquatic habitats in the Pipeline Maintenance Program are included in the riparian land cover type impacts. Aquatic impacts were also used to derive liner stream impacts</li> <li>• These analyses did not use GIS to derive total impact numbers</li> <li>• Impacts are calculated on an annual basis</li> </ul>
Staging	<ul style="list-style-type: none"> <li>• Identify acres of impact described in the Pipeline Maintenance Program EIR for upland impacts related to staging</li> <li>• Distribute acres of upland impact proportionally across all upland land covers in the study area</li> </ul>	<ul style="list-style-type: none"> <li>• Upland impacts assume that 5 pipelines are maintained per year; that there are up to 20 staging areas per pipeline in natural areas; and that each staging area is up to 100 ft by 100 ft</li> <li>• Impacts are applied to the proportion of land cover throughout the entire study area, inclusive of land covers excluded from the baseline data; this is based on the fact that SCVWD supply pipelines occur throughout the entire study area</li> <li>• Upland land covers include all land covers except the Riparian Forest and Scrub natural community land covers and the Reservoir land cover</li> </ul>
Off-road access	<ul style="list-style-type: none"> <li>• Identify acres of impact described in the Pipeline Maintenance Program EIR for upland impacts related to off-road access</li> <li>• Distribute acres of upland impact proportionally across all upland land covers in the study area</li> <li>• Identify acres of impact described in the Pipeline Maintenance Program EIR for riparian impacts related to off-road access</li> <li>• Distribute acres of riparian impact proportionally across all riparian land covers in the study area</li> </ul>	<ul style="list-style-type: none"> <li>• Upland impacts assume that 5 pipelines per year are maintained; up to 12 access points per pipeline; access areas are up to 15 ft by 1 mile</li> <li>• Riparian impacts assume that 5 pipelines per year in which they are maintained; up to 3 access points in riparian areas; access area would be up to 15 by 50 ft</li> <li>• Impacts are applied to the proportion of land cover throughout the entire study area, inclusive of land covers excluded from the baseline data; this is based on the fact that SCVWD supply pipelines occur throughout the entire study area</li> <li>• Upland land covers include all land covers except the Riparian Forest and Scrub natural community land covers and the Reservoir land cover</li> <li>• Riparian land covers include all land covers in the Riparian Forest and Scrub natural community</li> </ul>

Table 4-5f. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
Draining	<ul style="list-style-type: none"> <li>• Identify acres of impact to riparian and aquatic habitats described in the Pipeline Maintenance Program EIR</li> <li>• Distribute acres of impact proportionally across all riparian land covers in the study area</li> <li>• Identify linear ft of stream impacts described in the Pipeline Maintenance Program EIR</li> <li>• Distribute linear ft of stream impacts to the streams, or riverine, land cover type</li> </ul>	<ul style="list-style-type: none"> <li>• Riparian impacts assume placement of erosion control structures would impact up to 15 by 20 ft; up to 10 structures placed per year</li> <li>• Aquatic impacts assume that no more than 10 temporary flow check dams would be installed per year and that the maximum impact area per dam would be 5 ft by 25 ft</li> <li>• Stream impacts assume that the longest in linear stream feet that a temporary flow dam could be is 25 ft; assume 25 ft for each of the 10 installations per year</li> <li>• Impacts are applied to the proportion of land cover throughout the entire study area, inclusive of land covers excluded from the baseline data; this is based on the fact that SCVWD supply pipelines occur throughout the entire study area</li> <li>• Riparian land covers include all land covers in the Riparian Forest and Scrub natural community</li> </ul>
Excavation	<ul style="list-style-type: none"> <li>• Identify acres of impact described in the Pipeline Maintenance Program EIR for upland impacts related to excavation</li> <li>• Distribute acres of upland impact proportionally across all upland land covers in the study area</li> <li>• Identify acres of impact to riparian and aquatic habitats described in the Pipeline Maintenance Program EIR</li> <li>• Distribute acres of impact proportionally across all riparian land covers in the study area</li> <li>• Identify acres of wetland impacts described in the Pipeline Maintenance Program EIR</li> <li>• Distribute acres of wetland impacts to the seasonal wetland land cover type</li> <li>• Identify linear ft of stream impacts described in the Pipeline Maintenance Program EIR</li> <li>• Distribute linear ft of stream impacts to the streams, or riverine, land cover type</li> </ul>	<ul style="list-style-type: none"> <li>• Upland impacts assume up to 4 pipelines; excavation area per pipeline of 25 ft by 1 mile per pipeline; AND up to 10 point excavations of 25 ft by 25 ft each per pipeline</li> <li>• Riparian impacts assume a maximum of 3 excavations in riparian corridors per year, each excavation with a maximum footprint of 25 ft by 50 ft; also assumes a max of 1 acre per year of disturbance due to road repair</li> <li>• Aquatic impacts assume up to 3 blow-off points across all systems; excavation area of 25 ft by 50 ft</li> <li>• Wetland impacts assume up to 1 acre of wetland impact per year</li> <li>• Stream impacts assume 50 ft of stream impact per blow-off excavation; 3 excavations per year</li> <li>• Upland land covers include all land covers except the Riparian Forest and Scrub natural community land covers and the Reservoir land cover</li> <li>• Riparian land covers include all land covers in the Riparian Forest and Scrub natural community</li> </ul>
Excavation—bank stabilization	<ul style="list-style-type: none"> <li>• Identify acres of impact to aquatic habitats described in the Pipeline Maintenance Program EIR</li> <li>• Distribute acres of impact proportionally across all riparian land covers in the study area</li> <li>• Identify linear ft of stream impacts described in the Pipeline Maintenance Program EIR</li> <li>• Distribute linear ft of stream impacts to the streams, or riverine, land cover type</li> </ul>	<ul style="list-style-type: none"> <li>• Aquatic impacts assume 0.5 stabilizations per year; assumed to occur on each side of the channel; each side is 25 ft by 10 ft</li> <li>• Stream impacts assumes 0.5 bank stabilizations per year; each stabilization is 25 ft long</li> </ul>

Table 4-5f. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>County Roads and Airports</b>		
Road maintenance	<ul style="list-style-type: none"> <li>• In GIS, identify County mountain roads</li> <li>• Apply a 10 ft buffer to County roads</li> <li>• Overlay on the land cover layer to assess acres of impact by land cover type</li> </ul>	<ul style="list-style-type: none"> <li>• Assume a 10 ft maintenance buffer (20 ft width) (D. Cameron pers. comm.)</li> <li>• Assume all roads outside of a planning limit of urban growth will be maintained (impacts of road maintenance inside the planning limit of urban growth is incorporated into the urban development impacts)</li> <li>• Most (65%) of County roads occur in the valley floor area where shoulders are highly disturbed and often lacking vegetation; most impacts associated with road maintenance will occur on the 35% of County roads that are mountain roads that have vegetation on either side; only maintenance of mountain roads is assumed to have impacts to natural land cover (D. Cameron pers. comm.)</li> <li>• Stream impacts for road maintenance are identified under In-Stream O&amp;M for bridges</li> </ul>
South County Airport	<ul style="list-style-type: none"> <li>• In GIS, identify areas in the South County Airport that are not currently developed or proposed for development</li> <li>• Overlay area on land cover map</li> <li>• Exclude any in-stream areas</li> <li>• Subtract acres identified in Rural CIP projects from the total land assessed at the airport (first bullet)</li> <li>• Distribute remaining acres across land cover types in proportion to land cover type occurrence in the airport</li> </ul>	<ul style="list-style-type: none"> <li>• Lands identified in the South County Airport Master Plan as proposed aviation easements and proposed fee simple acquisition were not included in the analysis because these areas are not assumed to be affected by covered activities</li> <li>• Assume that all areas not identified for future permanent impacts will need to be maintained (mowed)</li> <li>• Assume that the County will avoid all impacts to in-stream areas</li> </ul>
<b>County Parks</b>		
Trail maintenance	<ul style="list-style-type: none"> <li>• In GIS, overlay the trail layer provided by the County on the land cover layer</li> <li>• Apply a 4 ft buffer</li> <li>• Assess acres of temporary impacts to land cover</li> </ul>	<ul style="list-style-type: none"> <li>• County Parks provided GIS for existing trails (J. Falkowski pers. comm. a)</li> <li>• Trails maintenance based on 4 ft buffer (8 ft total width) to both unpaved and paved County trails</li> <li>• Stream impacts are assessed under In-Stream O&amp;M activities</li> </ul>
Road maintenance	<ul style="list-style-type: none"> <li>• In GIS, overlay the road layer provided by the County on the land cover layer</li> <li>• Apply a 8 ft buffer</li> <li>• Assess acres of temporary impacts to land cover</li> </ul>	<ul style="list-style-type: none"> <li>• County Parks provided GIS for existing paved and non-paved roads (J. Falkowski pers. comm. a)</li> <li>• Service Roads and Paved Roads maintenance based on an 8 ft buffer (16 ft width)</li> <li>• Stream impacts are assessed under In-Stream O&amp;M activities</li> </ul>
Parking lot maintenance	<ul style="list-style-type: none"> <li>• In GIS, overlay the parking lot layer provided by the County on the land cover layer</li> <li>• Apply a 8 ft buffer around the perimeter of the lots</li> <li>• Assess acres of temporary impacts to land cover</li> </ul>	<ul style="list-style-type: none"> <li>• County Parks provided GIS for existing paved and unpaved parking lots (J. Falkowski pers. comm. b)</li> <li>• Paved and unpaved parking lots based on an 8 ft buffer around lot</li> <li>• No stream impacts are assumed</li> </ul>

Table 4-5f. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>Other</b>		
Utility line operations and maintenance	<ul style="list-style-type: none"> <li>• Convert 50 miles to ft</li> <li>• Multiply resulting number of ft by 15 ft width</li> <li>• Convert to acres</li> <li>• Distribute acres of impact</li> </ul>	<ul style="list-style-type: none"> <li>• 50 miles of lines maintained/replaced in the study area</li> <li>• Assume that 5 ft will be disturbed for excavating the utility; and 10 ft will be disturbed for access; total impact of 15 ft width</li> <li>• Assume that utility maintenance will proportionally impact all land cover types in the study area</li> </ul>

<sup>1</sup> All impact analyses are based on the baseline land cover as described in Chapter 4. Additional land cover parameters are identified in the Key Assumptions column.

<sup>2</sup> Unless otherwise noted, impacts to Urban-suburban, developed agriculture, landfill, and reservoir were excluded from final impact numbers because these land covers are assumed to either not provide any habitat value or will not be impacted in such a manner as to require conservation or mitigation (for the reservoir land cover).

<sup>3</sup> When using the method of impact distribution proportional to land cover, it is assumed that a project is likely to impact land covers in the same proportion at which land covers exist in a given project area. This approach may skew impacts higher for sensitive land covers that can be avoided through application of conditions on covered activities, design, and project siting, and skew impacts lower for impacts to less sensitive land covers that may be utilized in favor of impacting more sensitive land covers. Nonetheless, this impact analysis was conducted assuming any land cover can be impacted so long as it is not protected or excluded for other reasons (identified in the baseline data description).

**Note:** This table of impact analysis methods and key assumptions is not intended to be all inclusive. Rather, this table shows how impacts were calculated for covered activities that have impacts significant enough to be estimated. Minor activities described in Chapter 2 are covered under this Plan even though they may not appear in this table.

**Table 4-5g. Reserve System Permanent Impact Estimation Methods and Key Assumptions**

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>Implementing Entity and other Landowners that Implement Covered Activities within the Reserve System</b>		
Installation of signage (boundary, landbank, etc.)	<ul style="list-style-type: none"> <li>Identify acres in the Reserve System in thousands</li> <li>Multiply by 25%</li> <li>Distribute acres of impact to the grassland land cover</li> </ul>	<ul style="list-style-type: none"> <li>Assume that 0.25 acres per 1,000 acres of Reserve System will be affected by placement of signage</li> <li>Assume that the signage will be sited on grassland land cover</li> </ul>
Installation of new fences	<ul style="list-style-type: none"> <li>Approximately 278,000*2 sq ft</li> <li>Convert to acres</li> <li>Distribute acres of impact proportionally across all land cover types in the Reserve System</li> </ul>	<ul style="list-style-type: none"> <li>Assume that 278,000 ft of new fences will be installed over the permit term; equal to 53 miles</li> <li>Assume 2 ft wide permanent impact</li> <li>Assume that fences will proportionally impact all land cover types in the Reserve System</li> </ul>
Field facilities	<ul style="list-style-type: none"> <li>Identify number of facilities in Reserve System based on assumption</li> <li>Multiply by 1 acre</li> <li>Apply acres of impact to the grassland land cover</li> </ul>	<ul style="list-style-type: none"> <li>Assume 1 facility per 10,000 acres of Reserve System</li> <li>Assume 1 acre per facility will be affected</li> <li>Assume that the facility will be sited on grassland land cover</li> </ul>

Vehicle bridge replacement	<ul style="list-style-type: none"> <li>Approximately 10*2*39 sq ft</li> <li>Convert to acres</li> <li>Distribute acres of impact proportionally across all riparian and California annual grassland land cover types in the Reserve System</li> </ul>	<ul style="list-style-type: none"> <li>Assume 1 replacement every 5 years; 10 total</li> <li>Assume replacement bridges are 2 ft wider than existing bridges and 39 ft long</li> <li>Assume that bridges will proportionally impact all riparian and California annual grassland land cover types in the Reserve System</li> <li>No permanent stream impacts are assumed as any new impacts will be balanced with removal of an equal or greater amount of streams</li> </ul>
Trail bridges	<ul style="list-style-type: none"> <li>Approximately 25*8*39 sq ft</li> <li>Convert to acres</li> <li>Distribute acres of impact proportionally across all riparian land cover types in the Reserve System</li> </ul>	<ul style="list-style-type: none"> <li>Assume 2.5 bridges every 5 years; 25 total</li> <li>Assume 8 ft wide and 39 ft long (based on average bridge width and length for County Parks bridges)</li> <li>Assume that vehicle bridges will proportionally impact all riparian land cover types in the Reserve System</li> <li>No permanent stream impacts are assumed as any new bridges built will be balanced with removal of an equal or greater amount of bridges</li> </ul>
Trails	<ul style="list-style-type: none"> <li>Approximately 126*5280*5 sq ft</li> <li>Convert to acres</li> <li>Distribute acres of impact proportionally across all land cover types in the Reserve System</li> </ul>	<ul style="list-style-type: none"> <li>Assume 126 miles total trails will be built in the Reserve System</li> <li>Assume a 5 ft width will be affected</li> <li>Assume that trails will proportionally impact all land cover types in the Reserve System</li> </ul>
Trailhead facilities	<ul style="list-style-type: none"> <li>Identify number of trailhead facilities in Reserve System based on assumption</li> <li>Multiply by 5 acres</li> <li>Apply acres of impact to the grassland land cover</li> </ul>	<ul style="list-style-type: none"> <li>Assume 1 trailhead facility per 5,000 acres of Reserve System</li> <li>Assume 5 acres per facility will be affected</li> <li>Assume that trailhead facilities will be sited on grassland land cover</li> </ul>

<sup>1</sup> All impact analyses are based on the baseline land cover as described in Chapter 4. Additional land cover parameters are identified in the Key Assumptions column.

<sup>2</sup> Unless otherwise noted, impacts to Urban-suburban, developed agriculture, landfill, and reservoir were excluded from final impact numbers because these land covers are assumed to either not provide any habitat value or will not be impacted in such a manner as to require conservation or mitigation (for the reservoir land cover).

<sup>3</sup> When using the method of impact distribution proportional to land cover, it is assumed that a project is likely to impact land covers in the same proportion at which land covers exist in a given project area. This approach may skew impacts higher for sensitive land covers that can be avoided through application of conditions on covered activities, design, and project siting, and skew impacts lower for impacts to less sensitive land covers that may be utilized in favor of impacting more sensitive land covers. Nonetheless, this impact analysis was conducted assuming any land cover can be impacted so long as it is not protected or excluded for other reasons (identified in the baseline data description or Key Assumptions column).

**Note:** This table of impact analysis methods and key assumptions is not intended to be all inclusive of all covered activities. Rather, this table shows how impacts were calculated for covered activities that have impacts significant enough to be estimated. Minor activities described in Chapter 2 are covered under this Plan even though they may not appear in this table.

**Table 4-5h. Reserve System Construction Temporary Impact Estimation Methods and Key Assumptions**

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
<b>Implementing Entity and other Landowners that Implement Covered Activities within the Reserve System</b>		
Installation of signage (boundary, landbank, etc.)	No impacts assessed	<ul style="list-style-type: none"> <li>Assume that each project site is very small; no construction impacts assumed</li> </ul>
Installation of new fences	<ul style="list-style-type: none"> <li>Temporary impacts are equal to permanent impacts</li> </ul>	<ul style="list-style-type: none"> <li>An area equal to permanent impact is assumed for temporary construction impacts</li> <li>Assume that 278,000 ft of new fences will be installed over the permit term; equal to 53 miles</li> <li>Assume 2 ft wide permanent impact</li> <li>Assume that fences will proportionally impact all land cover types in the Reserve System</li> </ul>
Field facilities	<ul style="list-style-type: none"> <li>Approximately 10*220*4 sq ft per facility</li> <li>Multiply by number of facilities</li> <li>Convert to acres</li> <li>Distribute acres of impact</li> </ul>	<ul style="list-style-type: none"> <li>Assume 1 facility per 10,000 acres of Reserve System</li> <li>Assume a 10 ft buffer around a 1 acre footprint will be affected; and acre is approximately 220 ft by 220 ft</li> <li>Assume that the facility will be sited on grassland land cover</li> </ul>
Wells	<ul style="list-style-type: none"> <li>Approximately 10*22*4 sq ft per well</li> <li>Multiply by number of wells</li> <li>Convert to acres</li> <li>Distribute acres of impact</li> </ul>	<ul style="list-style-type: none"> <li>Assume 1 well per 1,000 acres of Reserve System</li> <li>Assume a 10 ft buffer around a 0.1 acre per well will be affected; 1/10 acre is approximately 22 ft by 22 ft</li> <li>Assume that the wells will be sited on grassland land cover</li> </ul>
Dirt roads	<ul style="list-style-type: none"> <li>Temporary impacts are equal to 5/6ths of the permanent impacts</li> </ul>	<ul style="list-style-type: none"> <li>Assume 40 miles of ranch road will be constructed over the permit term</li> <li>Assume 5 ft construction buffer (10 ft width)</li> <li>Assume that dirt roads will proportionally impact all land cover types in the Reserve System</li> </ul>
Paved roads	<ul style="list-style-type: none"> <li>Temporary impacts are equal to 5/12ths of the permanent impacts</li> </ul>	<ul style="list-style-type: none"> <li>Assume 0.25 miles of paved road will be constructed per year; 12.5 miles total</li> <li>Assume 5 ft wide buffer (10 ft width) will be affected</li> <li>Assume that paved roads will proportionally impact all land cover types in the Reserve System</li> </ul>
New vehicle bridges	<ul style="list-style-type: none"> <li>Temporary land cover impacts are equal to permanent impacts</li> <li>Multiply the width of each crossing by the number of crossings to get the total linear ft of temporary stream impact</li> </ul>	<ul style="list-style-type: none"> <li>“Bridges” includes all types of vehicle crossings including culverts</li> <li>An area equal to permanent impact is assumed for temporary construction impacts</li> <li>Assume 0.5 bridges every 5 years; 5 total;</li> <li>Assume 8 ft wide, and 39 ft long (based on average bridge width and length for County Parks bridges)</li> <li>Temporary stream impacts are assumed to equal the width of the crossing</li> </ul>

Table 4-5h. Continued

Covered Activity	Method of Impact Estimation	Key Assumptions <sup>1, 2, 3</sup>
Vehicle bridge replacement	<ul style="list-style-type: none"> <li>• Temporary land cover impacts are equal to permanent impacts</li> <li>• Multiply the width of each crossing by the number of crossings to get the total linear ft of temporary stream impact</li> </ul>	<ul style="list-style-type: none"> <li>• “Bridges” includes all types of vehicle crossings including culverts</li> <li>• An area equal to permanent impact is assumed for temporary construction impacts</li> <li>• Assume 1 bridge replacements every 5 years; 10 total</li> <li>• Assume replacement bridges are 2 ft wider than existing culverts and 39 ft long</li> <li>• Temporary stream impacts are assumed to equal the width of the crossing</li> </ul>
Trail bridges	<ul style="list-style-type: none"> <li>• Temporary land cover impacts are equal to permanent impacts</li> <li>• Multiply the width of each crossing by the number of crossings to get the total linear ft of temporary stream impact</li> </ul>	<ul style="list-style-type: none"> <li>• An area equal to permanent impact is assumed for temporary construction impacts</li> <li>• Assume 2.5 bridges every 5 years; 25 total;</li> <li>• Assume 8 ft wide and 39 ft long (based on average bridge width and length for County Parks bridges)</li> <li>• Temporary stream impacts are assumed to equal the width of the crossing</li> </ul>
Trails	<ul style="list-style-type: none"> <li>• Multiply permanent impacts by 10%</li> </ul>	<ul style="list-style-type: none"> <li>• Assume construction impacts are equal to 10% of the project footprint</li> <li>• Assume that trails will proportionally impact all land cover types in the Reserve System</li> </ul>
Trailhead facilities	<ul style="list-style-type: none"> <li>• Approximately 10*475*4 sq ft per facility</li> <li>• Multiply by number of facilities</li> <li>• Convert to acres</li> <li>• Distribute acres of impact</li> </ul>	<ul style="list-style-type: none"> <li>• Assume 1 trailhead facility per 5,000 acres of Reserve System</li> <li>• Assume a 10 ft buffer around a 5 acre footprint will be affected; 5 square acres is approximately 475 ft by 475 ft</li> <li>• Assume that trailhead facilities will be sited on grassland land cover</li> </ul>

<sup>1</sup> All impact analyses are based on the baseline land cover as described in Chapter 4. Additional land cover parameters are identified in the Key Assumptions column.

<sup>2</sup> Unless otherwise noted, impacts to Urban-suburban, developed agriculture, landfill, and reservoir were excluded from final impact numbers because these land covers are assumed to either not provide any habitat value or will not be impacted in such a manner as to require conservation or mitigation (for the reservoir land cover).

<sup>3</sup> When using the method of impact distribution proportional to land cover, it is assumed that a project is likely to impact land covers in the same proportion at which land covers exist in a given project area. This approach may skew impacts higher for sensitive land covers that can be avoided through application of conditions on covered activities, design, and project siting, and skew impacts lower for impacts to less sensitive land covers that may be utilized in favor of impacting more sensitive land covers. Nonetheless, this impact analysis was conducted assuming any land cover can be impacted so long as it is not protected or excluded for other reasons (identified in the baseline data description).

**Note:** This table of impact analysis methods and key assumptions is not intended to be all inclusive of all covered activities. Rather, this table shows how impacts were calculated for covered activities that have impacts significant enough to be estimated. Minor activities described in Chapter 2 are covered under this Plan even though they may not appear in this table.

**Table 4-6.** Covered Plant Occurrences and Estimated Permanent Impacts from Covered Activities

Species Name	Number of Extant Occurrences in California <sup>1</sup>	Number of Known Occurrences in Study Area <sup>1,2</sup>	Study Area Occurrences in Type 1 Open Space <sup>3</sup>	Study Area Occurrences in Type 1, 2, or 3 Open Space <sup>3</sup>	Permanent Impact Limit if No Additional Occurrences Found <sup>4</sup>	Impact Proportion on Known Study Area Occurrences (%)	Total Permanent Impact Limit if Additional Occurrences are Found and Protected in Study Area <sup>5</sup>

Most beautiful jewelflower	86	39	3	22	6	15%	8
<b>Total</b>	<b>490</b>	<b>362</b>	<b>12</b>	<b>148</b>	<b>32</b>	<b>9%</b>	<b>46</b>

Notes:

<sup>1</sup> Includes all CNDDB occurrences except those classified as "extirpated." See Chapter 3 and Chapter 5 for a complete list of data sources.

<sup>2</sup> For the purposes of this Plan and the analyses, occurrences are equivalent to populations for all species except for Mt. Hamilton thistle, Santa Clara Valley dudleya, and smooth lessingia. Populations may be redefined during implementation based on field monitoring and other data.

<sup>3</sup> Occurrences that are only partially in open space are not included in totals.

<sup>4</sup> This column provides the limit of impacts by number of occurrences allowable under the Habitat Plan. Impact is defined as a permanent loss of an entire occurrence or a partial loss that results in a reduction of viability (as further described in Chapter 6, Condition 20). See text for methods to determine whether partial impacts to an occurrence will be counted against the impact limit. The impact limit assumes that no new occurrences of the species are discovered during the permit term and that occurrences impacted are in worse condition than those protected within reserves (See Section 5.3.1. for a discussion on incorporating covered plant species into the Reserve System). Impact limits were determined based on estimated impacts of covered activities. In some cases, impacts were capped to ensure regulatory standards are met.

<sup>5</sup> Impact limits in this column are the total allowable impacts if additional natural occurrences (i.e., not created populations) are discovered and protected in reserves. Protected occurrences must be of higher conservation value than impacted occurrences. New occurrences must be found and protected before impacts occur. See Chapter 5 and Table 5-16 for protection ratios that must occur in order for impact limits to be increased.

<sup>6</sup> Loss of a population of this species is not allowed or needed due to covered activities. Impact is allowed to a portion of one population due to management actions within the Reserve System (e.g., prescribed burning) or inadvertent trampling due to livestock grazing.

<sup>7</sup> Impacts are allowed to no more than 3,650 individuals or 5% of the individuals in the population adjacent to Anderson Dam, whichever is smaller.

**Table 4-7. Assumptions of Land Cover Imperviousness**

Land Cover Type	Impervious Assumption <sup>1</sup>

Uvas sub-watershed							
Above Uvas Dam	19,441	251	1.3%	276	1.4%	24	9.7%
Below Uvas Dam	36,379	1,224	3.4%	2,027	5.6%	803	65.6%
<b>Note:</b> This analysis assumes that all interim projects (those projects entitled for development in advance of Plan implementation) that are located inside the planning limits of urban growth will be developed to the equivalent of the urban-suburban land cover type and that all interim projects located outside the planning limit of urban growth will be developed to the equivalent of the rural-residential land cover type.							

**Table 4-9. Estimated Impacts to Critical Habitat**

Species and Habitat Type	Total Critical Habitat in Study Area (acres)	Permanent Impact to Critical Habitat from Covered Activities (acres)	Proportion (%)	Temporary Impact to Critical Habitat from Covered Activities (acres)	Proportion (%)
<b>Bay Checkerspot Butterfly</b>					
Estimated Modeled Habitat overlapping Critical Habitat	7,616	<300 <sup>1, 2</sup>	4%	49	<1%
Estimated Critical Habitat outside Modeled Habitat <sup>3</sup>	8,985	437 <sup>4</sup>	49%	76	<1%
Maximum Allowable Impact to Total Critical Habitat	16,601	<550 <sup>2</sup>	3%	86 <sup>5</sup>	<1%
<b>California Tiger Salamander</b>					
Estimated Modeled Breeding Habitat overlapping Critical Habitat	92	1	1%	0	<1%
Estimated Modeled Non-Breeding Habitat overlapping Critical Habitat	27,235	263	1%	119	<1%
Estimated Critical Habitat outside Modeled Habitat <sup>3</sup>	769	8	1%	6	<1%
Maximum Allowable Impact to Total Critical Habitat	28,096	272	1%	125	<1%
<b>California Red-Legged Frog</b>					
Estimated Modeled Primary Habitat overlapping Critical Habitat	2,964	21	<1%	11	<1%
Estimated Modeled Secondary Habitat overlapping Critical Habitat	146,452	1,002	<1%	265	<1%
Estimated Critical Habitat outside Modeled Habitat <sup>3</sup>	1,546	12	<1%	5	<1%
Maximum Allowable Impact to Total Critical Habitat	150,962	1,035	<1%	277 <sup>5</sup>	<1%

Notes:

<sup>1</sup> Allowable permanent impact to Bay checkerspot butterfly critical habitat is capped below the estimated impact to account for the cap on impacts to Bay checkerspot butterfly modeled habitat in this Plan. This acreage is a cap, not an estimate.

<sup>2</sup> Impacts to modeled primary Bay checkerspot butterfly habitat are capped at 300 acres and impacts to serpentine bunchgrass grassland are capped at 550 acres.

<sup>3</sup> "Critical Habitat outside Modeled Habitat" is critical habitat area that does not overlap with habitat modeled for the Plan. Critical habitat is identified separately from modeled habitat because critical habitat is a relatively broad estimation based on "physical or biological features that are essential to the conservation of the species... if those features may require special management considerations or protection" (73 FR 50417). The modeling conducted for this Plan was done at a finer resolution than the critical habitat designation.

<sup>4</sup> Impacts to Bay checkerspot butterfly critical habitat could occur outside of modeled habitat on land cover types without impact caps. As such, allowable impacts to critical habitat outside of modeled habitat may be higher than allowed on modeled habitat. The cumulative cap on critical habitat is 550 acres.

<sup>5</sup> Allowable temporary impact to Bay checkerspot butterfly critical habitat and California red-legged frog critical habitat is capped below the estimated impact to hold impact levels constant with the Public Draft. Temporary impacts increased slightly due to the re-allocation of impacts to other locations in the study area due to the removal of State Parks lands from the impact analysis. This acreage is a cap, not an estimate.

Data sources: U.S. Fish and Wildlife Service 2005 (California tiger salamander), 2008 (Bay checkerspot butterfly), 2010 (California red-legged frog).

## Chapter 5

# Conservation Strategy

### 5.1 Summary

The conservation strategy was designed to meet the regulatory requirements of ESA and the NCCP Act and to streamline compliance with CEQA, NEPA, and other applicable environmental regulations (see discussion in Chapter 1). The conservation strategy provides mitigation for impacts on covered species on the basis of species and habitat needs. The conservation strategy mitigates all of the impacts described in Chapter 4, including direct, indirect, temporary, and permanent impacts. To meet the NCCP Act permit standards, the conservation strategy also contributes to species recovery to help to delist the listed species and prevent the listing of non-listed species through the protection, restoration, and enhancement of natural communities and species habitat. The conservation strategy also achieves the objectives listed below, pursuant to the NCCP Act (Section 2820).

- Conserves, restores, and provides for the management of representative natural and semi-natural<sup>1</sup> landscapes.
- Establishes reserves that provide conservation of covered species within the study area (i.e., contributes to species recovery) and linkages to adjacent habitat outside the study area.
- Protects and maintains habitat areas that are large enough to support sustainable populations of covered species.
- Incorporates in the reserves a range of environmental gradients and high habitat diversity to provide for shifting species distributions in response to changing circumstances.
- Sustains the effective movement and interchange of organisms between habitat areas in a manner that maintains the ecological integrity of the Reserve System.

Because the conservation strategy achieves the standards of the NCCP Act to contribute to species recovery, the strategy therefore exceeds the mitigation standards of the ESA. The conservation strategy is based on the best scientific data available at the time of its preparation and takes into account the limitations of the baseline data available for the study area (see Chapter 3 and **Appendix D**).

---

<sup>1</sup> A semi-natural landscape is defined as one that is disturbed by human activity but still provides important habitat for a variety of native species.

The conservation strategy is born out of the biological goals and objectives developed for the Plan and described below. To achieve these goals and objectives, a series of conservation actions have been developed that often meet multiple objectives or goals. The chapter is focused on conservation actions that will accomplish the following.

- Create a Reserve System by Year 45 of the permit term that will preserve a minimum of 33,205 acres and an estimated 33,629 if all impacts occur of newly acquired land for the benefit of covered species, natural communities, biological diversity, and ecosystem function.
- In addition to newly acquired land, incorporate 13,291 acres of existing open space into the Reserve System to enhance their long-term management.<sup>2</sup> The total size of the Reserve System will be at least 46,496 acres and up to an estimated 46,920 acres.
- Protect 100 miles of streams.
- Preserve major local and regional connections between key habitat areas and between existing protected areas.
- Establish a framework for long-term management of the Reserve System and streams throughout the permit area to enhance populations of covered species and maintain biological diversity.
- Restore minimum of 70 acres and up to 428 acres of riparian woodland and wetlands to offset losses of these land cover types and contribute to species recovery. All restoration construction will be completed by Year 40.
- Create a minimum of 20 acres and up to 72 acres of ponds to offset losses and contribute to species recovery. All creation construction will be completed by Year 40.

All of these actions will be accomplished by the Implementing Entity with partnerships with the Permittees, Santa Clara County Open Space Authority, landowners, possibly non-profit land conservation organizations, mitigation banks, and the state and federal government (see Chapter 9 for funding and land acquisition partnerships). This chapter does not describe avoidance and minimization actions; these and all other conditions on covered activities are addressed in Chapter 6.

## 5.2 Framework

The conservation strategy was designed using a multi-scale approach in accordance with principles of conservation biology. At the largest scale, biological goals and objectives were developed to encompass ecological

---

<sup>2</sup> This is the maximum acreage of existing open space that would be credited toward the Reserve System size under the Plan. Additional acres of existing open space could be incorporated into the Reserve System; however, they would not receive credit toward the Reserve System size. Alternatively, the Implementing Entity may acquire new lands for the Reserve System in place of adding this acreage from existing open space, as long as the total Reserve System size requirements are met.

processes, environmental gradients, biological diversity, and regional wildlife linkages. Conservation actions were developed to implement these goals and objectives. These conservation actions occur at the *landscape level*, generally at the scale of miles or tens of miles. At the middle level, conservation actions were developed to address natural communities primarily through the enhancement, restoration, and management of vegetation types (i.e., land cover types). This medium scale is called the *natural community level*. The final level addresses the specific needs of covered species for protection and enhancement of individuals, populations, and groups of populations. *Species-level* conservation actions were developed to supplement and focus actions developed at the broader levels and to ensure that all the needs of particular species are addressed.

This framework for the conservation strategy follows the multi-scale structure and approach advocated by Hunter (2005) that combines “coarse filter conservation,” “meso-filter conservation,” and “fine-filter conservation” (see **Figure 5-1**).

The conservation actions are described in Section 5.3 *Conservation Actions*; they are divided into land acquisition actions and actions at the natural community and species levels. All conservation actions are designed to have enough detail and specificity to allow implementation. Because of the large scale of this Plan and its long timeframe, actions are also designed to be flexible. For example, natural community-level actions provide broad management guidelines and principles such that future land managers can implement specific techniques on the ground that are best suited to site conditions. Preserving this flexibility is an important part of the conservation strategy.

Implementation of many actions will require the preparation of site-specific implementation documents. These plans will be prepared during Plan implementation after land is acquired and specific restoration and management needs are determined. Reserve unit management plans will guide activities within specific reserve units. Reserve units are defined as groups of contiguous or neighboring parcels that have similar natural communities, covered species, and infrastructure and therefore similar management issues. Reserve unit management plans for individual reserve units will be completed within 5 years of the first acquisition (fee title or easement) of the land for that reserve unit and submitted to the Wildlife Agencies for review and approval.

All conservation actions will be implemented using an adaptive management approach that is closely tied to long-term monitoring (see Chapter 7 *Monitoring and Adaptive Management Program*).

## 5.2.1 Biological Goals and Objectives

The Implementing Entity will achieve landscape, natural community, and species-level goals and objectives. Goals are broad, guiding principles based on the conservation needs of the resources. Biological objectives are expressed as

conservation targets or desired conditions. Objectives are measurable and quantitative when possible; they clearly state a desired result and will collectively achieve the biological goals **Figure 5-2**). Biological goals for covered species are required by USFWS's *5-Point Policy* to be included in HCPs (65 FR 35242, June 1, 2000)<sup>3</sup>.

All the biological goals and objectives on which this Plan is based are presented in **Tables 5-1a through 5-1d**. The conservation actions in this chapter contain detailed information on all aspects of reserve acquisition and management. They provide a strategy for how the goals and objectives will be achieved. It is expected that many of the details of the conservation actions will be modified during Plan implementation through the monitoring and adaptive management program, while goals and objectives will remain relatively static.

The 21 biological goals and 94 objectives in **Table 5-1** are organized by level: landscape level (**Table 5-1a**), natural community level (**Table 5-1b**) and species level (**Tables 5-1c and 5-1d**). At the species level, wildlife and plants are separated in order to make the tables more accessible. The 135 conservation actions that were designed to achieve each objective are shown in **Tables 5-2a and 5-2b**. **Table 5-2a** lists sequentially all land acquisition actions; **Table 5-2b** lists all management actions, broadly defined. One conservation action may contribute to multiple objectives or goals.

In some cases, conservation actions include the phrase “biologically appropriate” or “biologically feasible”. These phrases were added to conservation actions such as plant occurrence creation (see Section 5.3.1 subheading *Incorporating Covered Plant Species* for the definition of a plant occurrence) that are highly dependent on site conditions and other ecological contexts. These conservation actions will be implemented unless the Implementing Entity, with the concurrence of the Wildlife Agencies, determines based on further evaluation that the action is not biologically appropriate or biologically feasible but the biological goals of the Plan would still be fulfilled by implementing a more effective conservation action.

If the agreed upon conservation actions cannot be implemented and there are no alternatives that provide similar benefit and will achieve the biological goals, as agreed to by the Wildlife Agencies and the Implementing Entity, then coverage of the target species may need to be modified, reduced, or eliminated according to the process described in Chapter 10, Section 10.3 *Modifications to the Plan*.

---

<sup>3</sup> Due to the scope of this Plan, it was not possible to develop biological goals and objectives that strictly adhered to the Service's and NMFS' 5-Point Policy requirements as described in 65 FR 35251. That is, despite best efforts, the scope of the Plan precluded the Applicants from developing biological objectives that in all instances included species or habitat indicators, locations, actions, quantify/state, and timeframe. This information is presented in this chapter, which will be supplemented by implementation plans that will be reviewed and approved by the Wildlife Agencies (i.e., reserve unit management plans).

## Process of Developing Biological Goals and Objectives

The biological goals and objectives were initially developed through a series of six workshops composed of key technical staff from ICF Jones & Stokes, experts from the Wildlife Agencies, biologists and species experts from SCVWD, Local Partner staff, and outside species experts.

The purpose of each workshop was to collaboratively develop working draft biological goals and objectives. Each workshop began with an overview of the relevant natural communities and species, including key threats, ecological needs, and issues for the conservation strategy (e.g., potential conflicts with other species) by technical experts. Participants then worked through a set of preliminary draft goals and objectives developed by ICF and provided to participants prior to the workshop. Follow-up web-based conference calls or meetings were held at least once for every workshop to refine the goals and objectives to a point where all meeting participants were satisfied.

Every effort was made to create biological objectives that were quantitative as well as measurable. Workshop participants acknowledged that quantitative biological objectives may be somewhat subjective, but at least these quantitative objectives are explicit, clear, and transparent, and they serve as a starting point for conservation actions in the study area, including adaptive management and compliance monitoring (Margules and Pressey 2000).

Goals and objectives were frequently refined and updated as new analysis or new information was developed. In some cases, several possible quantitative targets emerged for an objective. These were carried forward as alternative approaches to meeting the same goal, and formed the basis for the alternative conservation strategies that preceded the selected conservation strategy. Biological goals and objectives were developed using the primary sources listed below.

- Ecological data from species accounts (**Appendix D**) and natural community descriptions (Chapter 3).
- Existing conservation targets or management recommendations for covered species in state or federal recovery plans or status reviews (Hays et al. 1999; U.S. Fish and Wildlife Service 1998a, 1998b, 1998c, 2002, 2006a).
- Other sources with conservation targets or conservation recommendations that address the covered species or the study area (Harrison et al. 1988; Weiss 1999; California Partners in Flight 2002; Klute et al. 2003; Ehrlich and Hanski 2004; Haight et al. 2004; Riparian Habitat Joint Venture 2004; Hamilton 2004; Trenham and Shaffer 2005; The Nature Conservancy 2006a).
- Critical habitat maps and data in published critical habitat rules for covered species (U.S. Fish and Wildlife Service, 2005, 2006b, 2008, 2010).
- Habitat distribution models developed for most of the covered species (see Chapter 3 and **Appendix D**).
- Results of the conservation gap analysis (see below).

- Input from resource specialists outside workshops including staff from the Wildlife Agencies.

When developing quantitative objectives, workshop participants recognized that conservation encompasses both mitigation and the need to contribute to species recovery. The level of this contribution to recovery was based, in part, on the proportion of the species' range within the study area. Quantitative biological objectives were established on the basis of relevant species-specific data. When data were not available, general guidelines or conservation "rules of thumb" were used to help establish quantitative biological objectives on the basis of the proportion of the species' current range within the study area (Margules and Pressey 2000) (**Table 5-3**).

Conservation of ecological processes, environmental gradients, regional biological diversity, and regional wildlife linkages were addressed primarily in the landscape-level biological goals and objectives. These goals and objectives were inherently difficult to develop because of the large scale of the processes and the general lack of data regarding their operation in the study area. The land cover mapping described in Chapter 3 was assumed to be an adequate surrogate for regional biological diversity. If adequate and representative stands of all of these land cover types are preserved and enhanced, it is assumed that native biological diversity in general will be preserved and enhanced.

## Biological Goals

Most of the biological goals and objectives are designed at least to conserve current populations of covered and other native species in the study area. In some cases, populations of covered species are expected to increase as a result of land preservation, improved water management, habitat enhancement, habitat restoration, and habitat creation.

Goals are listed below by level (see **Tables 5-1a through 5-1d**): landscape level, natural community level, and species level. The biological goals apply only to the Reserve System unless stated otherwise. Though most conservation actions will occur within the Reserve System, similar conservation approaches on private lands outside of the Reserve System will be encouraged during implementation. In cases where species conservation will occur outside the Reserve System (e.g., stream and riparian restoration), biological goals apply to the study area as a whole.

### Landscape-Level Goals (Table 5-1a)

- **Goal 1a.** Protect and maintain natural and semi-natural landscapes.
- **Goal 1b.** Protect and maintain ecological (natural) processes.
- **Goal 2.** Maintain or improve opportunities for movement and genetic exchange of native organisms within and between natural communities inside and connecting to areas outside the study area.

- **Goal 3.** Enhance or restore representative natural and semi-natural landscapes to maintain or increase native biological diversity.

### **Natural Community-Level Goals (Table 5-1b)**

- **Goal 4.** Maintain and enhance functional grassland communities that benefit covered species and promote native biodiversity.
- **Goal 5.** Maintain and enhance functional chaparral and northern coastal scrub communities to benefit covered species and promote native biodiversity.
- **Goal 6.** Maintain and enhance functional oak woodland communities to benefit covered species and promote native biodiversity.
- **Goal 7.** Maintain and enhance functional conifer woodland communities to benefit covered species and promote native biodiversity.
- **Goal 8.** Improve the quality of streams and the hydrologic and geomorphic processes that support them to maintain a functional aquatic and riparian community to benefit covered species and promote native biodiversity.
- **Goal 9.** Maintain a functional riparian forest and scrub community at a variety of successional stages and improve these communities to benefit covered species and promote native biodiversity.
- **Goal 10.** Maintain, enhance, and create or restore functional pond, freshwater perennial wetland, and seasonal wetland habitats that benefit covered species and promote native biodiversity.

### **Species-Level Goals (Tables 5-1c and 5-1d)**

- **Goal 11.** Improve the viability of existing Bay checkerspot butterfly populations, increase the number of populations, and expand the geographic distribution to ensure the long-term persistence of the species in the study area.
- **Goal 12.** Not used.
- **Goal 13.** Increase the size and sustainability of the breeding population and increase the distribution of breeding and wintering burrowing owls in the study area.
- **Goal 14.** Increase the ability of San Joaquin kit fox to move into and within the study area and provide habitat to increase the likelihood of breeding.
- **Goal 15.** Provide for the expansion of a breeding population of least Bell's vireos into the study area and increase reproductive success of least Bell's vireo.
- **Goal 16.** Conserve existing populations of the foothill yellow-legged frog population where possible and increase the overall population of foothill yellow-legged frog in biologically appropriate locations in the study area.

- **Goal 17.** Conserve existing populations of California red-legged frog, California tiger salamander, and western pond turtle where possible, and increase the number of individuals and expand the overall distribution of populations of these species in biologically appropriate locations within the study area to maintain viable populations and contribute to the regional recovery of these species.
- **Goal 18.** Increase the population size of tricolored blackbird to enhance the viability of the species in the study area.
- **Goal 19.** Not used.
- **Goal 20.** Maintain viability, protect, and increase the size and number of populations of covered serpentine plant species, including Coyote ceanothus, Santa Clara Valley dudleya, Metcalf Canyon jewelflower, most beautiful jewelflower, smooth lessingia, fragrant fritillary, Mt. Hamilton thistle, Loma Prieta hoita, and Tiburon paintbrush, within the study area.
- **Goal 21.** Protect and increase the size and number of Loma Prieta hoita within the study area.

## 5.2.2 Avoidance and Minimization Measures

As required by ESA, the Plan includes measures to avoid or minimize the impact of the taking of covered species. The primary focus of these measures is to avoid or minimize take of *individuals* of covered species (i.e., death or injury to species) and of high-quality habitat, such as streams and riparian areas that may be affected by covered activities. Others forms of take (e.g., harm or harassment of covered species) will still occur.

For example, an intent of certain measures is to encourage individuals of covered wildlife species to avoid or escape project construction zones. Occurrences of covered plants will also be avoided when adequate conservation of these species is not available within the Habitat Plan Reserve System. Activities within streams will be carefully designed and implemented to minimize their effects on this important resource and habitat for covered species. Impacts will also be minimized by requiring development projects adjacent to the Reserve System to be designed in ways that reduce their impacts on covered species and natural communities (as described in Chapter 6).

Areas designated for conservation and described in this chapter include substantial amounts of high-quality habitat for covered species and of natural communities, as well as areas important for maintaining regional biological diversity. Covered activities that result in permanent impacts are anticipated to occur primarily in areas with low-quality habitat. This *regional avoidance and minimization approach* to conservation of land cover and species habitat reduces the need to avoid or minimize impacts on habitats at the small or project scale. Avoidance and minimization measures at the landscape level are accordingly built into the Plan. Most habitat preservation and enhancement will be concentrated away from covered activities in the high-quality habitat of the

proposed Reserve System. Avoidance and minimization measures that apply to covered activities are described in detail in Chapter 6.

### 5.2.3 Reserve System

Land preservation is an important component of this conservation strategy. The term *land preservation* is intended broadly to specify the acquisition of terrestrial and aquatic land cover types. Land will be acquired from willing sellers in fee title or through establishment of conservation easements to create the Habitat Plan Reserve System. Land acquisition mechanics and processes are described in more detail in the Section 5.3.1 *Land Acquisition and Restoration Actions*. In order to become part of the Reserve System, lands must:

1. be consistent with the conservation strategy described in this chapter;
2. be approved by the Implementing Entity and Wildlife Agencies; and
3. be protected with a conservation easement<sup>4</sup> (see Chapter 8 for additional information).

Because management of riparian and stream land cover types takes place both inside and outside the Reserve System, specific acquisition and management priorities related to aquatic habitat are described in Section 5.2.4 *Aquatic Habitat Protection and Enhancement*.

## Reserve Design Process

The process for delineating and prioritizing land for acquisition corresponds to the scalar approach of the conservation actions (landscape-level, natural community-level, and species-level). First, consideration was given to large, core reserves that could accommodate large blocks of key land cover types (e.g., serpentine grassland) and covered species with large geographical ranges and specific habitat needs (e.g., areas with high densities of ponds to accommodate covered amphibians and reptiles). This level of design also considered expanding existing open space to create larger core reserves. Linkages were also considered so that habitat connectivity goals and objectives could be met (see discussion below). Next, the conservation of rare land cover types (e.g., serpentine seeps and rock outcrops) was considered. Finally, the conservation of species with small ranges was considered (e.g., covered plants). For resources not protected by the core reserves or the habitat linkages, smaller, “satellite” reserves will be proposed when necessary to protect isolated but important resources such as occurrences of covered plants and rare land cover types. In all cases, the Reserve System was designed to adhere to the reserve design principles discussed below with the least amount of acreage in order to efficiently achieve the conservation targets.

---

<sup>4</sup> The exception to the conservation easement requirement is existing lands listed in **Table 5-5** and owned by the Open Space Authority. See Chapter 9 for details.

Land use and economic factors in the Reserve System design were also considered in a step-wise manner. The first draft maps of the proposed Reserve System considered biological goals and objectives and maximized conservation benefit with the minimum amount of land. The second iteration of the maps took into account relevant land use and broad financial considerations. For example, areas with larger parcel sizes were selected over areas with very small parcels, all else being equal, due to the higher per-acre cost of small parcels. Areas without extensive rural development were favored over areas with such development, all else being equal, due to the habitat incursions and edge effects around rural development. In cases where the conservation priorities overlapped with covered activities, alternative conservation sites were sought. If an alternative conservation site was not available, then the covered activity was scaled back or dropped to allow for the conservation to occur. For example, urban development has been limited along stream corridors to ensure adequate conservation of stream and riparian systems (see Chapter 6, Condition 11 *Stream and Riparian Setbacks*). This step-wise approach enabled the proposed Reserve System to be developed independently from the covered activities but in a manner that quickly identified and resolved conflicts between them.

The independent Science Advisors and stakeholders provided early feedback on draft reserve design and assembly principles and the preliminary reserve design process. Reserve design alternatives were reviewed by all of the major land management and conservation organizations in the study area: County Parks, Open Space Authority, State Parks, The Nature Conservancy, and the Peninsula Open Space Trust, as well as staff from the Wildlife Agencies. Their valuable input was incorporated into the conservation strategy presented here.

## Reserve Design and Assembly Principles

The reserve design process utilized scientifically accepted tenets of conservation biology in concert with the best available biological data (Noss et al. 1995). Information on species (e.g., population biology, genetics, distribution, life history characteristics) and information on habitats (e.g., distribution, composition, ecological functions) informed the reserve design process. Relevant ecological data for covered species are summarized in the species accounts in **Appendix D**.

To be successful, a reserve system must be designed in consideration of multiple ecologically relevant spatial levels. Most small- and medium-level considerations are driven by the needs of covered species and natural communities. For example, at a small level, a reserve system must contain the microhabitats necessary for local populations of the species to survive. At a medium level, habitat patches must be large enough to support populations or important portions of populations of species and the seasonal movement of species (e.g., aquatic habitat for winter breeding of amphibians and upland habitat for non-breeding periods). At a larger level, natural communities must be well represented, and reserves must be linked to allow movement of species for genetic exchange and for recolonization following local extirpation. Biological goals and objectives pertaining to the acquisition and management of the Reserve

System were developed at these three levels as discussed above (Section 5.2.1 *Biological Goals and Objectives*).

In addition to the biological goals and objectives, the principles of conservation biology summarized below (Soule and Wilcox 1980; Soule 1986; Primack 1993; Noss et al. 1997; Margules and Pressey 2000; Groom et al. 2006) were used as design criteria for the Reserve System. The reserve design and assembly principles must also be used to assemble the Reserve System during Plan implementation.

- **Maximize Size Efficiently.** The Reserve System will be as large as possible within funding and management limits. It must be large enough to mitigate impacts of covered activities and contribute to the recovery of covered species in the study area. A large reserve system is important to ensure viable populations or portions of populations of covered species, to maximize protection of species sensitive to disturbances from adjacent land use, and to maximize the protection of biodiversity. Large reserves tend to support more species for longer periods of time than small reserves. Large reserves are also generally easier to manage on a per-acre basis because, for example, a large reserve reduces conflicts that may arise when managing for covered species with very different habitat requirements. Large reserves also better allow for large-scale management treatments such as prescribed burning and livestock grazing and the maintenance of natural disturbance regimes such as flooding. The only way to maximize size within funding and other constraints is to protect areas efficiently.
- **Preserve Irreplaceable and Threatened Resources.** Irreplaceability is a measure of the degree to which conservation goals can be met by preservation of multiple sites. A site with high irreplaceability has unique species or natural communities that cannot be preserved or restored elsewhere. An example of an irreplaceable resource in the study area is serpentine grassland, which cannot be replaced elsewhere once lost. Threatened resources are those most under threat from natural or anthropogenic factors. The Reserve System will first protect biological diversity and natural communities that have a high level of irreplaceability and a high degree of threat.
- **Preserve the Highest-Quality Communities.** The Reserve System will preserve the highest-quality natural communities and habitat for covered species in the study area. *Highest quality* is defined using various parameters and differs according to community type, but highest-quality habitats are frequently characterized by a high abundance and diversity of native species, intact natural processes, and few roads or other evidence of human disturbances. Degraded communities may need to be preserved as well to capture unique habitats or populations of covered species, to link preserve areas together, or to provide opportunities for land cover restoration required by this Plan.
- **Preserve Connectivity.** The Reserve System will link existing protected areas and proposed reserves inside and outside the study area to maximize habitat connectivity. This will maintain and enhance the ability of organisms to move between reserves; facilitate exchange of genetic material, species

migration, dispersal, and colonization; and increase the integrity of the network of reserves (e.g., reducing the extent of reserve edge that is in contact with adjacent land uses). Linking reserves may require acquisition of disturbed habitats that can be restored to facilitate better habitat and wildlife movement value. A single large reserve is generally better than several small, linked reserves of equal area in the context of maintaining viable populations of species. In some cases, however, small or isolated reserves are necessary to protect certain features or populations with high biological importance (e.g., covered plant species populations, unique or especially diverse land cover types such as serpentine grassland or scrub). Preserving connectivity will also tend to minimize habitat fragmentation.

- **Minimize Edge.** The Reserve System will share a minimum amount of edge (i.e., will have the greatest possible area-to-perimeter ratio) with non-preserve land, especially urban development, to minimize the indirect effects of adjacent land uses on the preserve resources and to minimize management costs. For example, preserves will tend toward round or square configurations rather than long and narrow ones. In some cases, however, preserves with low area-to-perimeter ratios may be appropriate to protect linear features with high biological value, such as streams, riparian woodland, valley bottoms, or ridgelines essential to wildlife movement.
- **Buffer Urban Impacts.** When adjacent to existing urban areas or planned urban areas (i.e., areas zoned for urban development), the Reserve System will include buffer lands within its boundaries. The purpose of this buffer land is to reduce indirect effects on covered species and natural communities from urban development and to provide a zone for fuel load management to reduce the risk of wildland fire spreading to adjacent development<sup>5</sup>. The size of the buffer will depend on site-specific conditions such as topography, the intensity of adjacent urban development, the natural community being separated from the development, the condition of the buffer lands, and whether covered species are or will be present near these lands. (See the section on *Buffer Zones within the Reserve System* below and Chapter 6, Section 6.4.6, subheading *Condition 10 Fuel Buffer*.)
- **Fully Represent Environmental Gradients.** The Reserve System will include a range of contiguous environmental gradients (e.g., topography, elevation, soil types, geologic substrates, slopes, and aspects) to allow for shifting species distributions in response to catastrophic events (e.g., fire, prolonged drought) or anthropogenic change (e.g., global warming).
- **Consider Watersheds.** The Reserve System will include a full range of catchment types, including watersheds, subwatersheds, and headwater streams that are not already in protected status; this approach can help to maintain ecosystem function and aquatic habitat diversity.
- **Consider Full Ecological Diversity within Communities.** The Reserve System will reflect the full ecological diversity within natural communities (e.g., species composition, dominant species, physical and climatic factors) in order to maintain sufficient habitat diversity and species and population interactions. This principle is also called *representativeness* and

<sup>5</sup> Consistent with California Public Resources Code 4291.

*comprehensiveness*. Some of the diversity within each of the Habitat Plan land cover types is described in Chapter 3.

- **Consider Management Needs.** Reserves will be manageable. That is, desired management treatments such as livestock grazing, prescribed burning, or invasive species control must be feasible on the reserve units and within the Reserve System. In general, larger reserves are easier to manage on a per-acre basis, but other factors such as adjacent land uses, topography, and parcel configuration must also be considered. Management needs may be driven by factors on or off site (e.g., adjacent land uses, watershed processes such as upstream erosion or ongoing contamination).

## Requirements of Covered Species

The Reserve System is intended to preserve and in many cases enhance populations of covered species. The ecological information used to determine the needs of covered species is summarized in the species accounts (**Appendix D**) and in this chapter.

### All Covered Species

The principles listed below, which apply to all covered species, were used to design the Reserve System and will be used to assemble the Reserve System during implementation.

- **Protect Multiple Populations of Covered Species.** In order to maintain viable populations of covered species, multiple populations of covered species will need to be protected and linked through existing or new protected lands to reduce the risk of local extirpation and ensure the genetic connectivity of populations. This is especially important for species that may function as metapopulations<sup>6</sup> or for species that naturally occur at low density or small population sizes.
- **Protect Higher-Quality Habitat for Covered Species.** Habitat Plan reserves were designed to protect the highest-quality habitat for covered species and allow most impacts to occur in lower-quality habitat.
- **Protect Suitable but Unoccupied Habitat for Covered Species.** Protecting suitable but unoccupied habitat for covered species creates opportunities to enhance habitat through improved management, attracting species to new areas and expanding their ranges and population sizes. Protecting unoccupied habitat also allows for future shifts in populations in response to natural and anthropogenic environmental change.

Consistent with the reserve design approach described above, the needs of covered species were considered at the landscape and habitat levels, and then

<sup>6</sup> A *metapopulation* is a group of partially isolated populations belonging to the same species that are connected by pathways of immigration and emigration. Exchange of individuals occurs between such populations, enabling recolonization of sites from which the species has recently become extirpated (locally extinct).

independently at the species level to ensure that each species' biological goals and objectives would be met. The conservation strategy in this Plan applies a "multi-species umbrella" approach (Lambeck 1997), where the species selected as covered species are the ones in the study area most under threat (i.e., those already listed or most likely to become listed during the permit term).

## Bay Checkerspot Butterfly

Early in the development of this Plan, it was recognized that one covered species, Bay checkerspot butterfly, would greatly influence the design of the Reserve System, particularly for the serpentine grassland land cover type. Because the study area supports all of the known populations and individuals of this subspecies throughout its range, a relatively high conservation target was set to protect it so that this Plan could contribute substantially to its recovery (**Table 5-1c**). Many of the serpentine plant occurrences also coincide with habitat for Bay checkerspot butterfly. In this sense, Bay checkerspot butterfly serves as an umbrella species<sup>7</sup> for many serpentine plants. For these reasons, the reserve design process began by determining the preservation needs of Bay checkerspot butterfly.

The reserve design for this species was a major focus of discussion at the biological goals and objective workshop held for serpentine species. The reserve design for Bay checkerspot butterfly had the benefit of extensive previous research and recommendations for specific reserve design strategies (e.g., Thomas Reid Associates et al. 1985; Harrison et al. 1988; Murphy 1988; Weiss et al. 1988; Murphy et al. 1990; Hanski et al. 2004). In addition, the USFWS Recovery Plan and revised critical habitat designation recommend specific land acquisition actions that could result in delisting of the subspecies (U.S. Fish and Wildlife Service 1998c, 2008). Many of these recommended actions were incorporated into the conservation strategy.

## Existing Open Space in the Reserve System

An estimated 117,686 acres, or 26% of the study area, are protected as Type 1, 2, 3, or 4 open space. These areas are already owned by public agencies or private conservation organizations or are subject to private conservation easements (**Figure 2-3, Table 2-2, and Table 5-4**). Type 1 open space is protected in perpetuity for the specific purpose of managing and protecting ecological integrity. Type 2 lands are also managed for the preservation of ecological integrity, but are not protected in perpetuity. Although ecological protection is not the primary management goal, Type 3 open space lands still provide some level of ecological value and function. Type 4 open space lands are not managed for ecological integrity and they offer little or no long-term or measurable ecological value. (See Chapter 2, Section 2.2.5 *Protection and Resource*

<sup>7</sup> *Umbrella species* are species whose occupancy areas are large enough and whose habitat requirements are broad enough that, once protection is established, it will bring other species under that same protection (e.g., Lambeck 1997; Fleishman et al. 2000; Rubinoff 2001).

*Management Status of Open Space Lands* for more discussion and examples of open space types.)

The Reserve System was designed to take advantage of the substantial amount of open space land already conserved within the study area. Existing Type 2 or 3 open space in the study area that contributes to the biological goals and objectives of the Plan are proposed for inclusion in the Reserve System as *existing open space*. Enrolled existing open space must conduct their management and monitoring according to the requirements and guidelines outlined in this conservation strategy and in Chapter 7 *Adaptive Management and Monitoring Program*. In many cases, this new obligation represents a substantial improvement over the type and level of habitat and species management and monitoring practices that are currently in place. In other cases, this requirement will simply standardize management and monitoring to provide a cohesive Reserve System throughout the study area, and ensure consistent management and monitoring in perpetuity. This upgrade and standardization of management and monitoring on existing open space therefore constitutes an important part of this conservation strategy.

To determine which existing open space would be eligible for the Reserve System, the criteria listed below were applied to all existing Type 2 or 3 open space.

- The site contributes to the biological goals and objectives of this Plan and meets many of the reserve design principles described above.
- The site provides clear opportunities for habitat enhancement that would provide substantial benefits to one or more covered species.
- The site is owned by one of the Permittees and the management agency cannot afford to conduct biologically appropriate habitat management, enhancement, or long-term monitoring.
- Land uses on and surrounding the site are compatible with the management and monitoring required by the Plan (e.g., if the site is small, adjacent land uses will not preclude use of necessary management actions).

Existing Type 2 or 3 open space sites proposed for inclusion in the Reserve System are listed in **Table 5-5** and illustrated on **Figure 5-4**. This table also lists how these areas will be enhanced and how they will contribute to the biological goals and objectives of the Plan. **Table 5-5** lists six park units owned by County Parks. Up to 1,000 acres of lands owned by the Open Space Authority may also be included in the Reserve System. State Park lands were also considered for the Reserve System but were not included because that agency declined to participate in this Plan. The Implementing Entity, with review and approval by the Wildlife Agencies, may incorporate existing open space not included in **Table 5-5** or shown in **Figure 5-4** if it is determined that other lands are able to support the biological goals and objectives of the Plan.

For a site to qualify and receive credit as part of the Reserve System, the Implementing Entity will obtain a conservation easement or similar mechanism that is approved by the Wildlife Agencies over these lands. The conservation

easement (or similar mechanism) will ensure that these lands are managed and monitored in perpetuity as part of the Reserve System and in accordance with the terms of the Habitat Plan (see Chapter 8, Section 8.6.3 *Conservation Easements* for details).

## Conservation Gap Analysis

A key step in the development of a conservation strategy for a regional HCP or NCCP is to determine the existing level of protection for natural communities and covered species. Species or natural communities with low levels of existing protection may require greater emphasis in the Plan to ensure that their conservation in the study area is assured and the regulatory requirements of the NCCP Act are met. In contrast, species or natural communities that are well protected may need little or no additional protection by the Plan. For these species, the conservation strategy may instead focus on habitat restoration or improved habitat management. For all species it is expected that enhanced management and monitoring on existing and new protected lands will be needed.

The analysis conducted to determine the levels of existing protection of species and natural communities is called a *conservation gap analysis*. The methods used were based on similar approaches applied at the national, state, and local levels (Scott et al. 1993, 2001; Wild 2002).

The gap analysis was used as a preliminary step in the conservation planning process to guide the reserve design process. Conservation biology theory holds that by protecting a wide variety of ecosystems and natural communities or land cover types at a broad level (i.e., a coarse-filter and meso-filter approach; see **Figure 5-3**), the majority of the biological diversity contained within these natural communities will also be protected (Noss 1987; Hunter 2005). This approach is then complemented by focusing on finer-level resources such as species occurrences, species habitat, or unique physical features to conserve biological diversity not protected by the broader-level approaches.

## Conservation Gaps in the Study Area

To determine the gaps in protection in the study area, the following GIS data layers were overlaid with the open space Types 1, 2, and 3 layer (**Figure 2-3**).

- Land cover (see Chapter 3 and **Figure 3-10**).
- Species habitat distribution (see Chapter 3 for a general description of these models and **Appendix D** for the model parameters for each species).
- Watersheds (see **Figure 3-6**).

The results of the conservation gap analyses are presented in **Table 5-4** for land cover types and **Table 5-6** for covered species. Data are presented by open space Types 1, 2, 3, and 4 (see Chapter 2 for a definition of open space types). Because of the importance of protecting substantial portions of occupied and suitable

habitat for Bay checkerspot butterfly, **Table 5-7** presents the gap analysis for the individual populations recognized in the species account (**Appendix D**). Together, these results constituted a key input to the conservation strategy and the design of the Reserve System.

### Gaps in Land Cover and Watershed Protection

Many natural land cover types have greater than 30% of their extent in open space Types 1, 2 or 3 (**Table 5-4**). Natural land cover types that are generally well represented in the study area in open space (>40%) are mixed oak woodland and forest, ponderosa pine woodland, coastal and valley freshwater marsh, willow riparian forest and scrub, blue oak woodland, seasonal wetland, reservoir, and central California sycamore alluvial woodland. Natural land cover types with the lowest proportion in open space overall and where the conservation gaps are most likely to occur are knobcone pine woodland, coast live oak forest and woodland, rock outcrop, serpentine rock outcrop, northern mixed chaparral/chamise chaparral, mixed riparian forest and woodland, and California annual grassland. Agricultural land cover types are poorly represented in open space in the study area.

Of the five major watersheds in the study area (Coyote, Pacheco, Llagas, Guadalupe, and Uvas), Type 1, 2, 3, or 4 open space is greatest in quantity and proportion in the Pacheco and Uvas watersheds (34 and 20%, respectively). The Alameda and Guadalupe watersheds have the least representation in open space Types 1, 2, 3, or 4 (1% each), followed by the Uvas and Llagas watersheds (15% each). In all five watersheds, the majority of land in open space is upstream of reservoirs. There is no Type 1, 2, 3, or 4 open space in the portion of the Santa Cruz Mountains watershed—which includes the headwaters of Pescadero Creek—within the study area (7,209 acres).

Of the 2,392 miles of mapped USGS blue line streams within the study area, approximately 34% are within Type 1, 2, or 3 open space. The Plan will also provide additional protection for ephemeral streams that are not mapped. The level of protection for these streams is generally high with approximately 16% in irrevocable protection and 34% of streams in Types 1, 2, or 3 open space.

### Gaps in Species Protection

As shown in **Table 5-6**, most covered species with models have moderate levels of representation in open space Types 1, 2, and 3, between 25% and 50%. Exceptions to this are San Joaquin kit fox secondary habitat and secondary habitat (low use); western burrowing owl overwintering, occupied nesting, and potential nesting habitat; tricolored blackbird secondary habitat; least Bell's vireo primary habitat; Loma Prieta hoita secondary habitat, and most beautiful jewelflower secondary habitat. Potential breeding habitat for least Bell's vireo is particularly underrepresented in Type 1, 2, or 3 open space (11%). No species' habitat occurs in open space Types 1, 2, and 3 above 50%.

**Table 5-7** presents more detail on the status of protection for all Bay checkerspot butterfly populations in the study area, because this species is one of the key species used to design the conservation strategy. As described in the biological goals and objectives for this species (**Table 5-1c**), some populations are targeted

for conservation. Of these targeted populations, more than two-thirds are in need of long-term protection, and the level of occurrence in open space by population varies from zero to 100%.

## Regional and State Gaps

Gap analyses conducted at scales larger than the study area were also considered to determine whether land cover types in the study area are underrepresented in Type 1, 2, or 3 open space compared to other regions or to regional conservation targets. For example, the conservation strategy in this Plan will contribute to regional conservation goals for land cover types found throughout the region.

Analysis at the regional scale entailed consulting a gap analysis conducted in the nine-county San Francisco Bay Area (Wild 2002). Although that study was conducted using an older and much coarser dataset<sup>8</sup>, it provided a wider regional context and helped to inform conservation priorities for the Habitat Plan. This study utilized a system of open space classification (based on Davis et al. 1998) similar to the one used in this Plan. **Table 5-8** lists the vegetative communities that are found in the study area (equivalent to Habitat Plan land cover types) that were identified as being underrepresented in protected status in the San Francisco Bay Area. Data are also presented in **Table 5-8** on the level of protection of these vegetation communities at the state level (Davis et al. 1998).

## Landscape Linkages

Landscape linkages were also used to design the Reserve System. For the purposes of this Plan, landscape linkages are defined as areas that allow for the movement of species from one area of suitable habitat to another. A linkage can vary from a narrow strip of habitat that only functions as a conduit for movement (i.e., a corridor) or a large area of intact habitat that is used for movement, dispersal, and other life functions such as foraging and breeding.

The NCCP Act explicitly requires NCCPs to address landscape or habitat linkages, as shown below.

Establishing one or more reserves or other measures that provide equivalent conservation of covered species within the plan area and linkages between them and adjacent habitat areas outside of the plan area.  
(Section 2820[a][4][B].)

Sustaining the effective movement and interchange of organisms between habitat areas in a manner that maintains the ecological integrity of the habitat areas within the plan area. (Section 2820[a][4][E].)

<sup>8</sup> This analysis utilized land cover data from the California Gap Analysis Project (Davis et al. 1998), which used aerial photography from 1990 and minimum mapping units of 247 acres (100 hectares) for upland communities and 98.8 acres (40 hectares) for wetland communities. In addition, the open space data are from 2002.

Some species require linkages for periodic migrations among different habitat types used for breeding, feeding, or roosting. Wildlife movement from one important habitat area to another may vary from daily to seasonal migration depending on the species. Linkages may also be needed for the permanent immigration or emigration of individuals among habitat patches, allowing for gene flow and recolonization after local extinction (Beier and Noss 2000; Hilty et al. 2006; Groom et al. 2006).

Linkage requirements differ greatly from species to species. Specific characteristics of linkages, such as dimensions, location, and quality of habitat, can influence species use. Wider linkages tend to be more effective than narrower linkages (Merenlender and Crawford 1998; Hilty et al. 2006).

To incorporate landscape linkages in the reserve design process, all known or potential linkages within the study area and in the surrounding areas were compiled from the following sources, in no particular order.

- Statewide assessment of wildlife linkages needs developed by expert opinions of wildlife biologists (California Wilderness Coalition 2002).
- Ecoregional planning process conducted for the central coast region (The Nature Conservancy 2006b).
- A study of movement needs of mountain lions estimated by least-cost path analysis of regional land cover data (Thorne et al. 2002).
- A local workshop on wildlife linkages in the Sierra Azul region<sup>9</sup> held on October 11, 2006 (Coastal Training Program, Elkhorn Slough National Estuarine Research Reserve 2006).
- Wildlife movement data from the study area for American badgers (Diamond 2006; T. Diamond pers. comm.), Tule elk (Coletto 2006; H. Coletto pers. comm.), bobcat, and other species (T. Diamond pers. comm.).
- Locations of existing culverts, bridges, and other overpasses suitable for wildlife along U.S. 101 between Metcalf Road in San José and the Coyote Creek bridge crossing near Morgan Hill (California Department of Fish and Game 2006).
- Locations of median barriers and existing culverts, bridges, and other overpasses suitable for wildlife along SR 152 between the SR 156 interchange and the Santa Clara/Merced County line (data collected by Jones & Stokes in February 2007).
- *Coyote Valley Specific Plan Draft Environmental Impact Report* (City of San José 2007).

Potential dispersal routes for plants and wildlife covered by the Plan were also inferred from the land cover data, compiled occurrence data, and habitat distribution models developed for this Plan (see Chapter 3 and **Appendix D**).

<sup>9</sup> The Sierra Azul region was defined to encompass the southern portion of the Santa Cruz Mountains south of Highway 17, the Diablo Range, and the Gabilan Range. The workshop focused on issues of connectivity between the Santa Cruz Mountains and the Diablo and Santa Lucia mountain ranges to the east and south.

The results of the compilation of these sources are described in **Table 5-9** as 20 distinct and potential landscape linkages found either entirely within the study area or within the study area that lead to outside the study area. **Figure 5-6** illustrates these 20 potential linkages, which are discussed below for their relative importance to the Habitat Plan. These linkages are drawn at a regional level as broad swaths of natural land cover types rather than specific alignments or corridors. Often there are multiple ways to protect land to achieve the linkage design in **Figure 5-6** and the goals in **Table 5-9**.

## Regional Connectivity

Maintaining linkages with areas outside the study area (i.e., regional habitat connectivity) is essential to retaining a high level of native biological diversity within the study area. For example, the southeast part of the study area may be an important linkage within the Diablo Range to the north and south (Linkage 15). The San Luis Reservoir in Merced County forms a significant barrier to terrestrial wildlife moving through the eastern Diablo Range, and the study area includes most of the Diablo Range west of the reservoir. Habitat continuity in this area likely benefits species such as San Joaquin kit fox. If kit foxes move from the Salinas Valley to the San Luis Reservoir area in Merced and Stanislaus Counties, they may use the southeastern part of the study area as a secondary route around the San Luis Reservoir.

The Santa Cruz Mountains on the western edge of the study area provide a connection for wide-ranging species between the Santa Cruz Mountains in Santa Cruz and San Mateo Counties and the Gabilan Range to the south. This connection is most apparent at the southern tip of the study area (Linkages 19 and 20) where there is a narrow linkage through the “Chittenden Gap” in Santa Cruz County to the Gabilan Range and the Santa Lucia Range to the south. If linkages like this are severed, populations of wide-ranging species (e.g., mountain lion) could be extirpated from the Santa Cruz Mountains because that range is likely insufficient in size to sustain a viable mountain lion population on its own (Thorne et al. 2002; Coastal Training Program 2006).

## Connectivity within the Study Area

Within the study area, many landscape linkages are important to maintain connections among populations. For example, the major stream corridors of Coyote Creek, Guadalupe River, Pacheco Creek, Uvas Creek, Llagas Creek, Pajaro River (Linkages 1, 2, 11, 12, 17, 18), and Pescadero Creek all support native fish species. These corridors also provide critical connections for other aquatic and terrestrial species moving through urban or cultivated agricultural areas.

There is considerable existing open space in the Santa Cruz Mountains both inside and outside the study area (**Figure 2-3**). Additional linkages could be made between existing open space within the study area (Linkages 9 and 13).

Such connectivity would benefit covered species such as California tiger salamander, California red-legged frog, and foothill yellow-legged frog, and other native species such as Coast Range newt, bobcat, and mountain lion.

Protected areas adjacent to Henry W. Coe State Park form a large nucleus of open space within the study area. These protected areas already provide landscape linkages for species such as California red-legged frog, California tiger salamander, Tule elk, American badger, bobcat, mountain lion, and mule deer. Additional landscape linkages would connect this large core open space with smaller protected areas and with key features outside the study area (e.g., Linkages 5, 6, 7, 14, 15, and 16).

## Linking the Santa Cruz Mountains and the Diablo Range

Historically, the Santa Cruz Mountains and the Diablo Range were linked across the Santa Clara Valley through a network of creeks, wetland complexes, and large stands of valley oak woodland (San Francisco Estuary Institute 2006). Over time this linkage has diminished with urban development, road barriers, and cultivated agriculture. Because some of the valley floor has remained in agricultural production and the creek corridors are largely intact, some connectivity remains (Linkages 8 and 10). There has been considerable debate recently about the best means to maintain this important connectivity between the Santa Cruz Mountains and the Diablo Range within the study area (Coastal Training Program 2006; City of San José 2007).

The connectivity between the Santa Cruz Mountains and the Diablo Range is expected to degrade further as covered activities are implemented. For example, development within Morgan Hill and Gilroy will make it more difficult for some wildlife species to cross the valley floor. While the Habitat Plan does not authorize incidental take associated with urban development in the Coyote Valley Urban Reserve at the southern end of San José, continued rural growth is expected to contribute to some long-term degradation (see Chapter 4). An important conservation objective of this Plan is to preserve and enhance the linkage between the two ranges (see Goal 2 in **Table 5-1a**). See landscape-level conservation actions in Section 5.3.2 *Landscape Conservation and Management* for more details.

## The Use of Maps to Define the Reserve System

Regional conservation plans take a variety of approaches in the use of maps to display land acquisition requirements. At one end of the spectrum, a conservation plan may use maps to delineate exactly where reserves are to be created. In this type of plan, often called a *map-based plan*, map designations define the application of regulations, fees, land acquisition, restoration, or other elements of the plan. Because all landowners must agree to the designation placed on their lands, purely map-based plans (otherwise known as *hard boundary* or *hard line* plans) are difficult to develop on a large scale and are rare.

At the other end of the spectrum, a conservation plan may display no maps or only very general maps and instead include a *process-based* land acquisition strategy. A purely process-based plan (also known as a *policy-based* or *criteria-based* plan) has no maps of where reserves will be established or other mitigation accomplished. Instead, the conservation plan outlines a detailed process by which reserves are assembled according to a set of clear criteria. The amount of flexibility in a process-based plan depends on the flexibility of the reserve assembly criteria.

The Local Partners considered the full range of available approaches and chose to employ a combination of these strategies. This Plan uses a hybrid approach in which maps display conservation priorities on a regional scale. Land acquisition will be undertaken in accordance with a detailed set of requirements, while maintaining flexibility in how the Reserve System is ultimately assembled. Although the final boundaries of the system cannot be known, the general location, size, configuration, and protected resources of the reserves are described in the conservation actions below. The Local Partners considered this element of the Plan to be essential to its success.

## Geographic Units of Conservation

The study area was subdivided into 34 discrete units called *conservation analysis zones* (**Figure 5-5**) to identify locations for conservation actions consistent with the hybrid approach to the use of maps described above. These zones define the areas in which conservation actions could occur outside existing protected areas. The primary purpose of these zones is to describe the specific areas in which conservation actions such as land acquisition will occur without identifying individual parcels. This focuses the conservation actions in a spatially explicit manner while maintaining the flexibility to conduct these actions on different parcels to meet the same conservation objectives (i.e., to respond to willing sellers where they arise). The arrangement of the zones also provides a mechanism to apply conservation actions at several spatial scales using consistent units (e.g., within a watershed, within a combination of zones, or within a single zone).

The conservation analysis zones were developed using subwatershed boundaries from the California Department of Water Resources (Calwater 221) that were aligned with the watershed boundaries used by the Habitat Plan. Existing open space (Types 1–3) was excluded from the zones. Subwatersheds smaller than 3,000 acres were merged with their adjacent larger subwatershed within the same watershed. Other adjustments were made to the zone boundaries to facilitate the conservation strategy; for example, the large Santa Clara Valley subwatershed that includes lower Llagas Creek was split into two subwatersheds for planning purposes<sup>10</sup>. Subwatersheds with mostly urbanized areas were also merged for convenience.

<sup>10</sup> In addition, the subwatershed surrounding Anderson Reservoir was merged with the adjacent three subwatersheds to create a less fragmented conservation planning unit.

Conservation analysis zones were defined within the six primary watersheds of the study area: Guadalupe, Coyote, Llagas, Uvas, Pacheco, and Pescadero (**Figure 5-5**). The portions of the study area within the Calabazas and San Tomas watersheds were combined into a single conservation analysis zone. Conservation analysis zones were numbered sequentially within each watershed generally from headwaters to their exit from the study area. The size and land cover types found in each conservation analysis watershed is shown in **Table 5-10**.

## Reserve Assembly Process

The Implementing Entity will establish the Reserve System through acquisition of land in fee title, conservation easement, or purchase of credits at an approved mitigation bank. Lands will only be acquired from willing sellers or donors and lands must meet one or more of the biological goals and objectives and the land acquisition requirements described below. The Implementing Entity will assemble the Reserve System in any of the following ways.

- Inclusion of land owned by a Permittee by conservation easement.
- Purchase of land in fee title from willing sellers.
- Purchase of conservation easements from willing sellers.
- Purchase of land or conservation easements in partnership with other organization(s) (not to be used as mitigation for another project that is not a covered activity).
- Acceptance of land or easement dedication in lieu of some development fees if the easement contributes to the goals and objectives of the Habitat Plan and is approved by the Implementing Entity and the Wildlife Agencies.
- Acceptance of credits sold in private mitigation banks approved by USFWS and CDFG if they meet the terms of the Plan (see Chapter 8, Section 8.6.2 *Land Acquired by Other Organizations or through Partnerships*, subheading, *Private Mitigation Banks*).
- Acceptance of land or easement dedication as a gift or charitable donation.

Acquisition of land in fee title or use of conservation easements will likely be the primary mechanisms used in most conservation analysis zones. Conservation easements will be used when the property owner wishes to enter that type of arrangement rather than sell land in fee title. The terms of each conservation easement may be tailored to each landowner and parcel, but will be consistent with goals of the conservation strategy, the general principles for easements outlined in this Plan (see Chapter 8), and the guidelines in the Implementing Agreement. The land and conservation easement acquisition process and the conditions under which the other four reserve assembly techniques may be used are discussed in detail in Chapter 8.

To achieve the Plan's biological goals and objectives, including contribution to the recovery of covered species, it is important to focus land acquisition where it

will have the greatest conservation benefit. By concentrating land acquisition in certain areas, larger effective reserves can be assembled by augmenting and connecting existing protected lands. However, the Implementing Entity must have flexibility in deciding where to acquire land because the Plan depends on the availability of willing sellers. The Plan balances these needs by focusing acquisition of certain land cover types within certain conservation analysis zones, as described below.

Despite this flexibility, the Implementing Entity will prioritize land acquisition in order to buy parcels of greatest conservation value (e.g., see *Reserve Design and Assembly Principles*, above) under the greatest threat of development and whose cost is expected to rise fastest. These criteria are met in conservation areas that span the floor of the Santa Clara Valley (Coyote-7, Llagas-3, Llagas-4) and the foothills immediately adjacent to the valley floor (Guadalupe 1, 3; Coyote-7, 8; Llagas-2, 3, 4; Uvas-1, 2, 5, 6; Pescadero-1).

When possible, land will first be acquired adjacent to existing protected areas to ensure that, in the unlikely event that funding does not become available for full acquisition of the Reserve System (see Chapter 9 for details), the Reserve System is composed of contiguous units rather than isolated parcels.

## Field Verification Prior to Acquisition

Land cover data, species occurrence data, and species habitat distribution models were developed for this Plan at a regional scale. The data and models were used to develop a sound conservation strategy for the study area at this regional scale. These data and models are not intended for site-specific planning because of the limitations described in Chapter 3.

To account for some of the uncertainty inherent in this conservation strategy, biological resources in potential conservation areas will, whenever possible, be verified in the field prior to land acquisition. The Implementing Entity will conduct *pre-acquisition assessments* on potential reserve lands to evaluate whether these lands are likely to meet Plan requirements. If a pre-acquisition assessment is not feasible, the Implementing Entity will conduct an assessment of the site based on air photo analysis and the best available regional data sets (e.g., Habitat Plan data, CNDDB).

The biological suitability of the site for the Reserve System will be determined on the basis of the information listed below.

- The results of past biological surveys, updated land cover mapping, assessments of habitat suitability for covered species, air photo interpretation, and the biological resources present or expected on site.
- An evaluation of the site's enhancement and restoration potential.
- An evaluation of how well the site achieves the reserve design principles listed above.

- An evaluation of the site's existing and potential biological value in the context of the remaining unmet biological goals and objectives and land acquisition requirements.

Types of information collected during these assessments will include an evaluation of location, quantity, quality, and type of covered species populations; covered species habitat; and natural communities present, as well as other site conditions or infrastructure that would benefit or conflict with the Plan's biological goals and objectives. The site's restoration and enhancement potential will also be evaluated. This information will help the Implementing Entity prioritize acquisition of reserve lands based on their relative contribution toward meeting the biological goals and objectives. More details on pre-acquisition assessments are found in Chapter 8.

## 5.2.4 Aquatic Habitat Protection and Enhancement

Protection and enhancement of aquatic habitat for covered species and other native species is an important goal of this Plan. Protection of off-stream aquatic habitats will be accomplished through the land acquisition process described below and through the stream and riparian setback requirement described in Chapter 6 (see Section 6.5, subheading *Condition 11 Stream and Riparian Setbacks*). In addition, the Plan requires restoration of aquatic land cover types to ensure no net loss in their extent and function within the study area.

The approach to stream and riparian woodland land cover protection and enhancement combines elements of land acquisition, restoration, and water management. The land acquisition strategy focuses on stream protection primarily in areas where large stands of riparian woodland are present, such as along Pacheco Creek, San Felipe Creek, and upper Uvas Creek. This focus has the dual benefit of protecting streams and riparian woodland habitats. Stream protection through land acquisition will also occur in areas most suitable for riparian woodland restoration to support covered birds, amphibians, reptiles, and native fish species.

Stream and riparian protection will also occur through the development review process when projects are proposed adjacent to streams. Through the stream and riparian setbacks condition (Condition 11 described in Chapter 6), applicants will be required to set aside stream frontage to protect stream and riparian functions. In some cases, high-value stream setback areas will be incorporated into the Reserve System to increase opportunities for riparian and stream restoration, and provide greater consistency in management and monitoring of these areas.

To enhance habitat for native fish species and covered amphibian and riparian bird species, broader strategies are needed than riparian woodland restoration in specific locations. To contribute to the recovery of covered amphibians and reptiles, the Plan will acquire and enhance upper watershed streams and associated upland riparian habitat throughout the study area. To enhance habitat

for least Bell's vireo and other native songbirds, the Plan will provide riparian restoration opportunities along Llagas Creek, Pacheco Creek, Uvas Creek, and the Pajaro River.

## 5.2.5 Land Management

The primary means of mitigating impacts on and conserving covered species and natural communities is preservation of high-quality habitat in accordance with the reserve design criteria outlined above. In order to meet regulatory requirements and to contribute to the recovery of covered species, habitat enhancement, restoration, and creation are also important components of the conservation strategy. Some land cover types that are lost to covered activities will be replaced with the same or similar communities or land cover types within the Habitat Plan reserves. Habitat enhancement, restoration, and creation ensure that there will be no net loss of certain resources (e.g., wetlands, breeding habitat for specific covered species). In other cases, restoration and enhancement are used to supplement preservation to adequately conserve land cover types or covered species habitat.

Some habitat-restoration requirements exceed those typically required for individual mitigation in order to contribute to the recovery or prevent listing of covered species that these habitats support. (These greater restoration requirements are also proportional to the stronger regulatory assurances provided by CDFG to the Permittees and private developers within the participating jurisdictions.) Depending on the resource, creation, restoration, or enhancement is required as part of the conservation strategy. Habitat enhancement, restoration, and creation will occur in addition to, not as a substitute for, land preservation. Success criteria for habitat enhancement, restoration, and creation will be based in part on reference stands in the region. Reference stands will be selected based on their condition as representative of high-quality communities in the study area. Such use of reference stands will allow habitat enhancement, restoration, and creation plans to incorporate any unique regional characteristics of these habitats. Each of these terms is defined below.

## Definitions

**Appendix A Glossary** has a complete list of definitions used in this Plan. The following are selected key definitions critical to the conservation strategy.

### Habitat Enhancement

*Habitat enhancement* is the manipulation of the physical, chemical, or biological characteristics of a land cover type to heighten, intensify, or improve one or more specific existing ecological function(s). Enhancement results in the gain of selected existing ecological function(s), but may also lead to a decline in other ecological function(s). Habitat enhancement implemented in the Reserve System will result in an increase or improvement in specific ecological function without

a change in the amount of land cover types. Examples of ecological functions include native species richness, species diversity, native vegetative cover, and wildlife habitat.

Examples of habitat enhancement include:

- Planting valley oak seedlings in an existing stand of valley oaks to increase oak cover and density and improve the age-class structure of the valley oak population.
- Manipulating the growth stage composition of vegetation on a site.
- The reduction or removal of one or more threats to covered species or natural communities, including:
  - The treatment and removal of invasive species including bullfrog removal, weed abatement, and prescribed burning (see **Appendix D** for a discussion of threats to each covered species).
  - Permanently protecting Reserve System lands to remove threats of development, overcollecting, overgrazing, lack of grazing, and others.
  - Fencing installation and repair to support improved livestock grazing and prevent unauthorized access.
  - Reducing hazards to animal movement by adding or resizing culverts or reducing traffic on private roads within the Reserve System.

Enhancement actions will differ according to each natural community and site. For example, some communities in the study area have inherently low productivity, low species richness, or low vegetation cover. Enhancement of these communities may be measured by an increase in relative cover of native plants or a decrease in inappropriate disturbance.

The appropriate type of habitat enhancement will be considered on a site-by-site basis by the Implementing Entity within the context of the entire Reserve System and Plan goals and objectives. Habitat enhancement will occur on all lands preserved in the Reserve System. The level of habitat enhancement will vary greatly within the Reserve System. For example, degraded communities will need a higher degree of enhancement than lands with little or no degradation. Some natural communities will need little to no management unless changed circumstances occur; in these cases, permanent protection of the land and the removal of key threats may be the only enhancement occurring on those sites.

Habitat enhancement will be informed by pre-acquisition assessments, targeted studies and by the monitoring and adaptive management program, to conserve the populations of all covered species and maintain or improve ecological processes.

## Habitat Restoration

*Habitat restoration* is the manipulation of the physical, chemical, or biological characteristics of a site with the goal of returning natural or historic functions to a site that historically supported such functions, but no longer does because of the loss of one or more required ecological factors or as a result of past disturbance.

Restoration typically involves altering the soil or other substrate to improve a site's ability to support the historic land cover types, although it may also include physical manipulation to restore specific ecological function in a site where that function has been lost (e.g., removal of hardscape in a stream channel and re-vegetation with riparian plantings). In contrast to enhancement, restoration results in the re-establishment of ecological function, value, and acreage of a natural community or land cover types.

For example, riparian woodland could be restored to stream reaches that historically supported them. In this Plan, habitat restoration is only allowed in those land cover types for which techniques are generally successful, and where restoration would substantially enhance habitat for covered species and native biological diversity. Restoration actions must also incorporate the best available science.

Habitat restoration may not restore all functions of natural communities. For example, recent studies of wetland restoration projects indicate that many of them fail to meet success criteria or lack important functions of natural reference sites (National Research Council 2001). The conservation strategy takes this uncertainty into account by relying primarily on habitat preservation and by requiring habitat restoration in amounts exceeding typical mitigation ratios. Also, uncertainty is taken into account by the adaptive management strategy (see Chapter 7 *Monitoring and Adaptive Management Program*).

Habitat restoration will be focused in the Reserve System, including existing open space that may become part of the Reserve System. Riparian and stream restoration that is counted towards the total conservation benefit of the Plan (**Table 5-13**) is allowed on private or public lands outside the Reserve System (i.e., without a conservation easement) as long as the following conditions are met.

- Restoration is conducted by a Permittee, including the Implementing Entity, or a third party under contract with a Permittee.
- Restoration is done consistent with the *Reserve Design and Assembly Principles* described in Section 5.2.3<sup>11</sup>.
- The site is restored to pre-project or ecologically improved conditions within 5 years of the end of the covered activity.
- A Wildlife Agency-approved site restoration plan is developed consistent with the requirements in Section 5.3.6 *Riverine and Riparian Forest and*

<sup>11</sup> Restoration efforts need to remain in compliance with the Plan's Stay-Ahead provision, described in Section 8.6.1.

*Scrub Conservation and Management*, subheading *Riparian Restoration*, subheading *Site Restoration Plan*.

- There are no suitable and feasible restoration sites within the Reserve System.
- The restoration project meets the riverine and riparian and requirements described below in Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management*.
- The site is maintained in perpetuity according to the terms of the Plan by the Implementing Entity or a Permittee. If the site is maintained by a third party, the third party must enter into a contract with the Implementing Entity to ensure management according to the terms of the Plan.
- The Implementing Entity, or its designated third party, monitors the restoration site in accordance with Chapter 7.
- The Implementing Entity and Wildlife Agencies approve the project.

One exception to the requirement that the site be maintained in perpetuity is that restoration projects occurring on streams managed for flood control and human safety purposes may be adversely modified (i.e., modified such that the restoration no longer serves the functions for which it was designed) by future covered activities. In such cases, any adverse modification of a restoration site will be off-set by new restoration in an alternative location(s). New restoration actions must be initiated in advance of the new covered activity that would adversely modify the restoration site. All such arrangements will be discussed and approved by the Wildlife Agencies as soon as the Permittees or Implementing Entity become aware of such a need.

All restoration conducted outside of the Reserve System will be tracked by the Implementing Entity to ensure that the site is monitored and managed consistent with the requirements of the Plan for the Reserve System. These projects will also be identified in the annual report.

Stream and riparian restoration outside of the Reserve System (i.e., on lands not under a conservation easement) is likely to constitute a small proportion of the Plan's commitment to riparian and stream restoration (**Table 5-13**) because the Implementing Entity will prioritize all feasible sites within the Reserve System. In addition, restoration must comply with the Plan's reserve design and assembly principles which include, but are not limited to, preservation of the highest-quality communities, preservation of connectivity, and consideration of management needs. Furthermore, the Wildlife Agencies will also need to approve restoration outside of the Reserve System.

## Habitat Creation

*Habitat creation* is the manipulation of the physical, chemical, or biological characteristics present to develop a land cover type in an area that did not previously support it. Similar to restoration, creation results in establishment of

new ecological function, value, and acreage of a natural community or land cover types.

The only habitat creation proposed under this Plan is for ponds. Ponds will be created as breeding habitat for California red-legged frog or California tiger salamander in areas along streams that did not previously support ponds. This type of habitat creation must be balanced by the need to maintain and enhance stream functions. No on-stream ponds will be constructed in drainages that support, or could support, covered species under this Plan. Habitat creation will occur in damaged or disturbed areas to minimize the loss of existing habitats by the creation of new ones. Ponds may also be created in other appropriate areas as long as there is normally enough water, or a water source may be established (e.g., installation of a spring box or a well) to adequately maintain the necessary inundation schedule for the target species.

In-kind/like-function habitat creation is the establishment of the same land cover type as the land cover type lost to the covered activity, and that would establish the same type of ecological functions over time. For example, creating an artificial pond with species similar to those found in a natural pond would be in-kind/like-function creation.

Out-of-kind/like-function creation of habitat is the establishment of a different land cover type with some of the same ecological functions as the affected land cover type. Out-of-kind/like-function creation or restoration is not allowed under the Habitat Plan except in situations where historic physical conditions can be restored to recreate a community that has been lost historically. For example, sycamore alluvial woodland and alkali wetland may have been more common in the study area before human alterations of the landscape (San Francisco Estuary Institute 2006, 2008). If conditions supporting these communities could be restored, then the historic communities could be recreated out-of-kind.

## Land Management on Reserves

Reserve management is designed to maintain and enhance natural communities, habitat for covered and other native species, native biological diversity, and ecosystem function. The location of reserves and condition of resources within these reserves will not be known until suitable sites are identified, surveyed, and acquired. Therefore, site-specific management objectives and techniques cannot be developed until reserve sites are known. The Implementing Entity will prepare a *reserve unit management plan*.

Reserve unit management plans will be developed for each reserve unit to identify, on the basis of site-specific conditions and reserve objectives, the management and maintenance actions necessary to ensure that desired ecosystem characteristics and functions are maintained and enhanced. Reserve units are defined as groups of contiguous or neighboring parcels that have similar natural communities, covered species, and infrastructure. Reserve unit management plans must address and minimize the conflicts that may arise when managing for multiple species and habitats. Reserve unit management plans will also describe

reserve-specific actions to address invasive species, fire management, infrastructure maintenance, recreation, monitoring, agricultural activities, and mosquito abatement as applicable.

Separate reserve unit management plans will be prepared for a minimum of five reserve units. These reserve units are expected to support similar land cover types, covered species, and habitats, and will therefore face similar management issues. A list of likely reserve units is presented below based on the expected geographic distribution of the Reserve System.

- Upper Penitencia Creek,
- Coyote Ridge,
- Pacheco Watershed,
- Southern Santa Cruz Mountains, and
- Santa Teresa Hills.

The Implementing Entity may decide to prepare additional reserve unit management plans to address more specific geographic areas of the Reserve System.

All reserve unit management plans must be prepared in collaboration with the Wildlife Agencies and approved by the Implementing Entity and the Wildlife Agencies. In cases where reserve unit management plans include land that remain in private ownership (i.e., conservation easements but not fee title), plans will also be prepared in collaboration with applicable landowners. The Wildlife Agencies will review each draft reserve unit management plan and provide comments to the Implementing Entity within 60 days after receiving the draft plan. The Implementing Entity will revise the draft plan based on the Wildlife Agencies' comments, if any, and will provide a revised draft to the Wildlife Agencies, which will have an additional 60-day review period. If an initial draft reserve unit management plan or any subsequent revised draft reserve unit management plan adequately addresses a Wildlife Agency's comments, the Wildlife Agency will so notify the Implementing Entity within 60 days, and the reserve unit management plan will be deemed to be approved by that Wildlife Agency for purposes of this Plan, the Implementing Agreement, and the permits. In addition, if a Wildlife Agency does not provide comments within 60 days after receiving the revised draft reserve unit management plan, the Wildlife Agency will thereafter be deemed to have approved the revised draft plan for purposes of this Plan, the Implementing Agreement, and the permits. The Implementing Entity will incorporate comments submitted by the Wildlife Agency after the 60-day period in the revised draft reserve unit management plan to the extent that the Implementing Entity determines the comments can be incorporated.

Comments from the Wildlife Agencies will focus on implementation of the management techniques described in this chapter or introduction of new techniques associated with the adaptive management program and in response to monitoring results (see Chapter 7). The deadlines described above are established to ensure the timely review and comment on the reserve unit

management plans by Wildlife Agency staff and to enable the Implementing Entity to implement conservation actions as soon as possible.

Reserve unit management plans will also be updated and revised as part of the adaptive management program (Chapter 7). Land management on new reserves must not wait until adoption of the first reserve unit management plan; until the first reserve unit management plan is approved, land management will occur according to the guidelines in this chapter and best scientific practices. The conservation actions below describe the objectives, principles, and general requirements of these reserve unit management plans.

## Reserve Unit Management Plans

Reserve unit management plans will be prepared by the Implementing Entity for each reserve unit for natural land cover types (i.e., on land not cultivated or irrigated for crops or pasture; see the next section for management of other lands). Reserve unit management plans will describe reserve-specific management strategies for maintaining, and when necessary, improving existing habitat conditions for covered species. These plans will also facilitate the management of enhanced/created/restored habitats, to maintain or improve their functions over time through the adaptive management process. The Implementing Entity should consider developing decision trees or flow charts for certain types of management such as prescribed burning or invasive species management (e.g., Starfield and Bleloch 1991).

Reserve unit management plans will be prepared as soon as reasonably possible but not longer than 5 years following acquisition of the first parcel in a reserve unit or of placing a conservation easement on the parcel. This time period will provide an opportunity to conduct thorough inventories of the site's resources over several seasons. It will also provide the time necessary to seek review and approval from the Wildlife Agencies. Reserve unit management plans will be developed in partnership with adjacent land management agencies, resource agencies, and current grazing lessees, if any. In cases where reserve unit management plans include land that remain in private ownership (i.e., conservation easements but not fee title), plans will also be prepared in collaboration with applicable landowners. Input from interested citizens will be included in reserve unit management plan development through public outreach and education (see *Public Education and Outreach* below). When possible, new or updates to existing reserve unit management plans will be coordinated with concurrent open space planning processes of the agency that owns the site (e.g., County Parks Master Plan).

Until the first reserve unit management plan is developed and formally approved by the Wildlife Agencies, reserve lands will be managed in the interim to maintain and improve covered species habitats in accordance with the guidance in the Plan, best available information, and management methods currently being used in the study area. Subsequent reserve units will be managed in the interim based on reserve unit management plans for other units of the Reserve System.

Until a reserve unit management plan is prepared, management regimes that existed prior to acquisition will continue until it can be shown through management on other Habitat Plan reserves or elsewhere in the study area, pilot studies, experimentation, or other relevant studies that changing management will benefit natural communities or covered species. If the pre-existing management was damaging the resource or resources contained in that reserve, interim actions, based on best available information, will be implemented immediately and continued until the specific reserve unit management plan is completed. For example, if a parcel was previously overgrazed, the stocking rate could be reduced to the point where it can reasonably be assumed that the modified level of grazing will sustain natural resources. The reserve unit management plan will then define the appropriate standards to provide for reserve enhancement in perpetuity.

As described in Chapter 9, development fees are the primary source of funding for management actions and other operational activities in the Reserve System. Due to the slow pace of development in the study area as a result of the recent recession, it is unclear whether development fees will be adequate to fully fund management of the Reserve System in the early years of Plan implementation. In the event that development fees cannot fully fund management in reserve units according to the requirements and guidelines in this conservation strategy, the Implementing Entity may conduct only essential management tasks and defer non-essential management tasks for up to 5 years from the first acquisition for each reserve unit, or when development fees become available, whichever comes first. Essential management tasks are defined as those tasks necessary to ensure that the reserve unit does not degrade below the existing condition at the time it was incorporated into the Reserve System in terms of natural land cover and covered species habitat. Existing conditions will be documented by the Implementing Entity through the pre-acquisition assessment and the site inventory, described in Chapters 7 and 8. Management in response to changed circumstances (i.e., remedial actions described in Chapter 10) cannot be deferred.

Reserve unit management plans will be working documents; accordingly, they will not preclude the modification of management measures prior to Plan updates in cases where adaptive management or new research identifies more effective techniques. The Implementing Entity will review and, where biologically appropriate, systematically revise reserve unit management plans at least every 5 years. This review will be based on an evaluation of the success of management methods (i.e., knowledge gained through the monitoring and adaptive management program) in achieving objectives of the reserve, as well as on results of other outside research. As applicable to each reserve unit, reserve unit management plans will include the following types of information.

### **Objectives of the Conservation Area**

Each reserve unit management plan will clearly identify the biological objectives for the reserve unit. Biological objectives for each reserve unit will be a subset of the biological goals and objectives of the Habitat Plan (**Table 5-1**). Each reserve unit management plan will also identify the conservation actions applicable to the reserve (**Table 5-2**).

## Vegetation Management

Each reserve unit management plan will describe reserve-specific objectives for the following goals.

- Reducing the abundance and distribution of invasive plants.
- Increasing or maintaining the abundance and distribution of covered plants, and of compatible native plants in general.
- As indicated by pre-acquisition assessments and targeted studies and informed by the monitoring and adaptive management program, reducing the fuel load of the reserve so that the risk to biological resources of catastrophic wildfire is at an acceptable level and the risk to adjacent urban areas is minimized (meeting all state and local requirements). The methods and intensity of fuel management will vary depending on the location of the reserve relative to human populations and structures; emergency vehicle access; and the sensitivity of resources in the reserve to fuel load reduction techniques (e.g., fuel breaks, prescribed fire, mowing). Because fuel load reduction in chaparral habitats may be problematic (i.e., high-quality chaparral habitat is frequently characterized by periodic wildfire), it may be necessary to establish buffers in which to implement fuel load reduction.
- Minimizing the impacts of vegetation management techniques on native biological diversity and covered species (some impacts on covered species from vegetation management are expected and are included in the take allowances provided in this Plan).

Each reserve unit management plan will identify the types of management actions and the implementation schedule required to achieve the vegetation management objectives. Anticipated methods for managing vegetation include, but are not limited to, the following.

- Livestock grazing.
- Prescribed burning.
- Mechanical mowing (e.g., mowing fire breaks near the end of the growing season around the margins of reserves or as an alternative to grazing in areas where livestock cannot be used; large-scale use of heavy machinery to remove vegetation will not be allowed).
- Hand removal of vegetation (e.g., to remove infestations of invasive plants and to increase abundance of early successional vegetation along dense riparian corridors downstream of reservoirs).
- Biological control agents, where biologically appropriate and when shown to have minimal risk to non-target native species.
- Application of herbicides (e.g., spot spraying to remove infestations of invasive plants). There may be a need to apply herbicides on a large scale (e.g., to control yellow star-thistle). Note that use of herbicides is not proposed for coverage in the Section 10(a)(1)(B) permits. Herbicide use should consider the County of Santa Clara Integrated Pest Management Program and Pesticide Use Ordinance Section B28-10.

Reserve unit management plans will also describe the ongoing vegetation management actions that must be undertaken to implement community-level actions required on each of the reserves. This chapter includes detailed recommendations for management techniques and principles grouped by natural community that must be incorporated appropriately into each reserve unit management plan. These measures describe management requirements and guidelines that will be applied to natural communities to benefit covered and other native species.

- Section 5.3.2 *Landscape Conservation and Management.*
- Section 5.3.3 *Grassland Conservation and Management.*
- Section 5.3.4 *Chaparral and Northern Coastal Scrub Conservation and Management.*
- Section 5.3.5 *Oak and Conifer Woodland Conservation and Management.*
- Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management.*
- Section 5.3.7 *Wetland and Pond Conservation and Management.*

### **Management of Invasive Species**

Each reserve unit management plan will include a section on management of invasive species. This section will incorporate management tools for controlling and if possible eradicating invasive plants and animals. Actions to control invasive animals (bullfrogs, nonnative predatory fish and feral pigs) that are described in Section 5.3.2 will also be incorporated as relevant into individual reserve unit management plans. In addition, California tiger salamander hybrid management, discussed in **Appendix K**, will be addressed in relevant reserve unit management plans.

### **Fire Management**

Each reserve unit management plan will include a section on fire management. The fire management section of each reserve unit management plan will include a description of minimum impact suppression techniques, which are described in more detail below. The plans will also include the following elements specific to each reserve:

- A map of fire access roads and gates.
- Identification of fuel-load management methods and criteria for their application.
- Criteria and procedures for use of prescribed fire for management purposes (burn plan).
- A description of fire-suppression criteria, procedures, resources, and responsibilities, including criteria for selecting fire-fighting water sources.
- A discussion of restoration/rehabilitation of vegetation following a fire.

Fire is an important natural component of local ecosystems. Therefore, some wildfires will be allowed to burn naturally to provide periodic disturbances that

will benefit natural communities and covered species, within the larger land-use context. The fire management component of each reserve unit management plan must include a clear decision system to determine when a wildfire will be left to burn and when it must be partially or wholly contained to prevent damage to structures, prevent injuries, prevent impacts to neighboring properties (including loss of forage and livestock), or cause excessive disturbance to natural communities.

The fire management component of each reserve unit management plan must be consistent with achieving the biological objectives of the reserve, as well as associated regulatory requirements. Reserve fire management components will be coordinated with the California Department of Forestry and Fire Protection (Cal-Fire) and any other firefighting agency that has responsibility for Reserve System lands. Copies of all fire plans, including maps of access roads, gates, and biologically sensitive areas, will be provided to all firefighting units. Additionally, the plans may include prescribed burn guidelines for management of fire-dependent natural systems. This would include coordination with other land management entities to assure adequate availability of burn permits from the Bay Area Air Quality Management District.

The development of the fire management component of each reserve unit management plan will include, based on the location of existing access roads and gates, an assessment of the need to develop additional fire access roads sited to minimize impacts on sensitive species and communities and to minimize the need for new access roads (which could affect sensitive species and communities) to be constructed under emergency conditions (i.e., during fires). In addition, all access gates will include common locks, inventoried and regularly checked by the Implementing Entity, which will allow for ready access by firefighting agencies.

### **Maintenance of Infrastructure**

Each reserve unit management plan will include a map showing the location of infrastructure, such as livestock grazing infrastructure, roads, firebreaks, fences, gates, pumps, wells, water control structures, ditches, canals, drains, powerlines, and buildings. The reserve unit management plan will include a schedule for inspecting infrastructure to determine the need for maintenance. Work needed to maintain infrastructure that is necessary for maintaining reserves (e.g., firebreaks, fences) will be conducted as soon as practicable after the need for maintenance has been identified. The reserve unit management plan will also identify periods during which maintenance activities will be conducted to avoid or minimize adverse effects on natural communities and covered species. Applicable avoidance and minimization measures described in Chapter 6 will also be applied. The Implementing Entity will include as a section in the reserve unit management plan a hazardous materials management/spill prevention plan to identify procedures that must be followed if hazardous materials are encountered or a spill occurs on the reserve.

### **Monitoring Requirements and Adaptive Management**

Each reserve unit management plan will include monitoring and adaptive management for the species, threats, and management actions within the reserve.

All management actions described in the reserve unit management plan will take into account the adaptive management program described in Chapter 7. Reserve unit management plans will include a description of how the results of the effectiveness monitoring will be used to adjust management of the reserve unit within the decision-making structure of the adaptive management process.

### **Recreational Use**

The participation of County Parks and the Open Space Authority in the conservation strategy requires that public access be permitted within the Reserve System. For Reserve System lands that permit public access, each reserve unit management plan will address recreational use that is compatible with the preservation and enhancement of natural communities, covered species, and biological diversity on the reserve. The recreation component of the reserve unit management plan will apply the allowances and restrictions described in Condition 9 to the management unit.

### **Agricultural Lands**

The Habitat Plan does not require acquisition of cultivated agricultural lands (i.e., grain, row-crop, hay, disk/short-term fallowed land cover type or irrigated pastures). However, acquisition of a larger site could include some cultivated agricultural land. For reserves that include cultivated agriculture, each reserve unit management plan will describe the agricultural practices that will be undertaken to ensure the land's compatibility with the Habitat Plan. The reserve unit management plan will also include limitations on permitted practices to reduce adverse effects of some practices on covered and other native species. Ongoing agricultural practices will be allowed if they are compatible with the goals and objectives of this Plan. If these ongoing agricultural practices are not compatible with the goals and objectives of this Plan, the parcel will either not be incorporated into the Reserve System or portions of an individual parcel with incompatible uses will be excluded from the Reserve System. Agricultural lands receive credit and enrollment into the Reserve System only if the site supports the biological goals and objectives of the Plan.

The key elements of the agricultural component (e.g., conservation goals and standards) will be negotiated with the landowner and included in the conservation easement when this form of ownership interest is acquired. The agricultural component will include details on the techniques and tools that will be used to achieve these goals. See Chapter 8 for the required elements of these easements, including the prohibitions on uses that would degrade the conservation value of the easement land. Preparation of reserve unit management plans will include opportunities for public review and comments.

### **Mosquito Abatement**

Any mosquito control activities to be performed on Reserve System land will be addressed in the reserve unit management plan in consultation with the Santa Clara County Vector Control District. The Implementing Entity will work with the Santa Clara County Vector Control District to create a unified mosquito control strategy that will apply to the entire Reserve System. All reporting requirements will be consistent with those required by the Santa Clara County Vector Control District and the U.S. Department of Agriculture. The reserve unit

management plan will include specific detail related to that unit. It will also explain specific measures implemented to avoid and minimize impacts to covered species consistent with the Habitat Plan.

## 5.2.6 Alternative Conservation Strategies

To facilitate the decision-making process, three alternative conservation strategies were developed that served as the basis for the preferred conservation strategy described in this chapter. Before the alternatives were developed, the Permittees established the following criteria, all of which had to be met for an alternative conservation strategy to be considered.

- Meet all applicable regulatory standards of ESA and the NCCP Act.
- Be technically feasible.
- Provide real choices in action and cost.
- Reflect the range of preferences of local agencies and stakeholders.
- Be easily distinguishable (i.e., vary as few parameters as possible).
- Support the CEQA/NEPA process, if possible.

Affordability was considered as a criterion and the Permittees felt that, while the preferred alternative must be affordable, it may be useful to have an alternative that is potentially unaffordable. Such an alternative helps to establish the “maximum practicable” conservation strategy, as required by ESA.

The alternative strategies developed differed primarily in the amount and location of land acquisition required. The details of the three alternative conservation strategies were released in June 2007 in the preliminary working draft of Chapter 5. Land acquisition ranged from 30,000 acres in Alternative 1 to 40,000 acres in Alternative 2 to 58,000 acres in Alternative 3. The alternatives also differed in the amount of existing open space incorporated into the Reserve System. Alternative 1 relied heavily on existing open space while Alternative 3 did not rely on any existing open space; Alternative 2 relied on a moderate amount of existing open space for the Reserve System. The three alternative conservation strategies were considered by the Wildlife Agencies and the Stakeholder Group in a series of meetings between July 2007 and June 2008 and through written comments. The public was also given the opportunity to review the alternative conservation strategy at a public meeting on September 26, 2007.

To develop the preferred conservation strategy, elements were taken from each alternative to best meet the biological goals and objectives of the Plan with the least cost. Although Alternative 3 would result in the greatest benefit to the covered species and natural communities, it was determined that this alternative was unaffordable and would result in infeasible development fees. The preferred land acquisition strategy, as described below in Section 5.3.1 *Land Acquisition and Restoration Actions*, combines elements from all three alternatives but mostly falls between Alternatives 2 and 3 in scale and scope.

## 5.2.7 Data Sources

The primary sources of data for the conservation strategy were the ecological accounts of covered species (**Appendix D**), the species distribution models (**Appendix D**), and the inventory of existing conditions summarized in Chapter 3. Other sources consulted to develop the conservation strategy are cited throughout the chapters. Additional general sources are listed below.

- Species recovery plans, if available (California Red-Legged Frog [U.S. Fish and Wildlife Service 2002], Least Bell's Vireo [U.S. Fish and Wildlife Service 1998b], Serpentine Soil Species of the San Francisco Bay Area [U.S. Fish and Wildlife Service 1998c], Upland Species of the San Joaquin Valley [U.S. Fish and Wildlife Service 1998a]).
- Species and natural community experts, including the independent Science Advisors for the Plan.
- Approved or in-process HCPs for adjacent or nearby areas with similar natural communities and covered species (e.g., San Francisco Public Utilities Commission Alameda Watershed HCP (ICF International 2010a) [in process], Pacific Gas and Electric Company Bay Area Operations and Maintenance HCP (ICF International 2010b) [in process], East Contra Costa County HCP/NCCP (Jones & Stokes 2006) [approved]).
- Local land acquisition priorities of open space agencies and organizations, where they overlap with the biological goals and objectives of the Plan: County Parks (County of Santa Clara 1987), Open Space Authority, The Nature Conservancy (The Nature Conservancy 2004, 2006b), National Audubon Society (National Audubon Society 2008), and Peninsula Open Space Trust.
- Management or mitigation plans for large-scale projects in the study area that address biological goals and objectives similar to those of the Plan (e.g., Kirby Canyon landfill, SR 152/156 Interchange).

## 5.3 Conservation Actions

The conservation strategy is composed of a series of *conservation actions*. Conservation actions are tools, strategies, comprehensive programs, and actions to conserve natural communities, habitats, and landscape-level processes and to conserve and help recover covered species in the study area. Tiering off of the biological goals and objectives (Section 5.2.1 *Biological Goals and Objectives*), conservation actions also occur at the landscape-level, natural community-level, and species-level. Conservation actions are grouped into two major categories—land acquisition actions and management actions—and are given unique labels and numeric codes according to their topic area. All conservation actions are listed sequentially in **Tables 5-2a and 5-2b**. The relationship of these conservation actions with the biological goals and objectives is presented in at the landscape-level (**Table 5-1a**), the natural community-level (**Table 5-1b**) and species-level (**Tables 5-1c and 5-1d**). Included as management actions are

studies that will address key management questions related to the covered species and natural communities (**Table 5-2b**). The results of these studies will be incorporated into the adaptive management process described in Chapter 7. Therefore, management actions will be adjusted in response to the results of these studies.

The following subsections describe in detail the landscape-level and natural community-level conservation actions. Section 5.4 *Benefits of and Additional Conservation Actions for Covered Species* relates the landscape-level and natural community level conservation actions to each covered species, while also discussing in detail the species-level conservation actions.

### 5.3.1 Land Acquisition and Restoration Actions

An important part of the conservation strategy is the creation of a Reserve System. Many parts of the Reserve System will link existing protected areas with newly protected lands. When completed, this Reserve System will protect substantial areas of high-quality habitat for covered species and will provide extensive new opportunities for habitat enhancement, restoration, and creation. The term “land acquisition” includes acquisition of all aquatic land cover types including wetlands, ponds, and streams.

All lands in the Reserve System will be enhanced, as indicated by pre-acquisition assessments and targeted studies and informed by the monitoring and adaptive management program, to improve habitat for covered species and natural communities. The details of habitat enhancement activities are described starting in Section 5.3.2 *Landscape Conservation and Management*. Habitat restoration and creation will occur in targeted sites for wetlands, streams, and ponds as described in Sections 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management* and 5.3.7 *Wetland and Pond Conservation and Management*.

The land acquisition process is described in Chapter 8, Section 8.6 *Land Acquisition*. All land acquisition will be proposed to CDFG and USFWS for review and approval to ensure consistency with the biological goals and objectives.

## Acquisition Requirements by Land Cover Type

### Acquisition Requirements for Terrestrial Land Cover Types

The minimum land acquisition required under the Habitat Plan for terrestrial land cover types is 32,850 acres, as shown in **Table 5-11**. Additional minimum land acquisition requirements apply to some conservation analysis zones and for aquatic land cover types, as described below. Actual acquisition of some land cover types will likely be greater than the combined minimum requirements

because parcel boundaries typically do not follow ecological boundaries, and the boundaries of acquired parcels will include land cover types that are not specified by acquisition requirements<sup>12</sup>. In addition, qualitative requirements for habitat connectivity or for preservation of plant occurrences could require additional acreage.

All terrestrial land acquisition must be accomplished by Year 45 of the permit term. This requirement is in place to ensure that all lands incorporated into the Reserve System have at least 5 years to be managed, enhanced, and monitored according to the terms of the Plan before the permits expire. This time period will enable the Wildlife Agencies to closely monitor the final land acquisitions to ensure the Implementing Entity will complete the land acquisition strategy and achieve the final biological goals and objectives. Management of these lands however, will occur in perpetuity.

To estimate the actual extent of the Reserve System, the amount of land that would need to be acquired to meet all the requirements of this Plan was estimated. The actual size of the Reserve System will be different than the estimated amount because of the uncertainty in which parcels are acquired. Regardless of the final Reserve System size, all land acquisition requirements described in this chapter must be met by Year 45 of the permit term.

## **Acquisition and Restoration Requirements for Aquatic Land Cover Types**

As described above, the primary approach to conservation of terrestrial land cover types is through preservation and enhancement of lands based on regional estimates of impacts and the conservation needs of the covered species and natural communities. The approach to mitigating and conserving aquatic land cover types (wetlands, ponds, streams, and riparian woodland and scrub) differs from the approach to other land cover types. As described in Chapter 4, there is greater uncertainty in the degree of impact on aquatic features than on other land cover types. This is due, in part, to the uncertainty in some of the land cover mapping (particularly regarding wetlands; see **Table 3-4**). It is also due to the coarse scale of development designations within the local jurisdictions relative to the scale of these aquatic features. For example, even though an area may be designated for residential development, it is anticipated that residential projects will, for the most part, avoid riparian woodland and streams within their boundaries. Because it is difficult to predict the level of onsite avoidance, the Habitat Plan utilizes conservation ratios that are tied to actual impacts during Plan implementation to determine the necessary level of conservation.

All wetlands, ponds, and streams to be affected or preserved will be delineated in the field prior to impacts or acquisition as described in Section 6.8.4. Delineations may not always be feasible prior to acquisition for the Reserve System. Since land will be acquired on a willing seller basis, the Implementing

<sup>12</sup> For example, a 1,000-acre parcel may have required land cover types on 950 acres. Therefore, the remaining 50 acres of the parcel would not count towards Plan requirements.

Entity will need to respond quickly and may not always have the opportunity to conduct a pre-acquisition delineation. If infeasible, a delineation would occur within one year of acquisition. To offset impacts on these aquatic land cover types, the Implementing Entity will acquire these land cover types in-kind within reserves according to the ratios in **Table 5-12**. As with terrestrial land cover types, all aquatic land cover types must be acquired by Year 45. This requirement is in place to ensure that all lands incorporated into the Reserve System have at least 5 years to be managed, enhanced, and monitored according to the terms of the Plan before the permits expire. This time period will enable the Wildlife Agencies to closely monitor the final land acquisitions to ensure they will complete the land acquisition strategy and achieve the final biological goals and objectives.

To ensure a minimum level of protection of wetlands and other aquatic land cover types and ensure contribution to recovery for the covered species, regardless of the level of impact, the Implementing Entity must acquire at least 250 acres of riparian forest and scrub, 40 acres of central California sycamore alluvial woodland, 10 acres of coast and valley freshwater marsh (perennial wetland), 5 acres of seasonal wetland, 50 acres of ponds, and 100 miles of streams as shown in **Table 5-13**. Because there is a finite amount of these relatively rare land cover types in the study area not already protected in open space, the minimum protection levels can be met through preservation needed for mitigation. In addition, the preservation ratios for aquatic land cover types include a recovery component. For example, if all 25 acres of impacts occur to coastal and valley freshwater marsh, then 50 acres of this land cover type must be preserved in the Reserve System. Because of the limited availability of this land cover type, the minimum preservation of 10 acres will be fulfilled by the preservation of 50 acres (i.e., it may be infeasible to make the mitigation and minimums additive). In another example, if only 2 acres of impacts occur to coastal and valley freshwater marsh, then the minimum of 10 acres of preservation must occur (applying the mitigation ratio of 2:1 only reaches 4 acres of preservation).

Aquatic land cover types will also be restored or created according to the ratios in **Table 5-13**. Guidelines for restoration and creation for each natural community are described in the sections below on each natural community. All restoration and creation construction must be completed by Year 40 of the permit term. This requirement is in place to ensure that there is at least 10 years before the end of the term in which to monitor success criteria and take remedial actions in the event that success criteria are not being met.

To ensure a minimum level of restoration or creation that will contribute to species recovery, the Implementing Entity will restore or create 50 acres of riparian woodland, 20 acres of freshwater marsh, 20 acres of ponds, and 1 mile of streams (**Table 5-21**). These restoration and creation requirements are in addition to those required to offset impacts to these land cover types. To ensure that the Implementing Entity makes steady progress towards the final minimum creation and restoration goals, interim deadlines are established for each of the five applicable land cover types (**Table 5-14**). Interim deadlines are established for Years 15, 30, and 40.

Wetlands and streams exhibit a high degree of biological, physical, and hydrologic diversity in the study area. Consequently, it is important to preserve, enhance, restore, or create the full diversity of these land cover types as they occur in the area. Wetland delineations conducted prior to wetland impacts will be used, in part, to classify wetland types lost to ensure that the same types are being acquired and restored or created within Habitat Plan reserves. In addition, vegetation in wetlands and streams will be classified at the association or alliance level (rather than as a single land cover type) in order to help ensure that a diversity of communities is preserved.

Limits on impacts on aquatic land cover types are described in **Table 4-2** and preservation will occur in accordance with the preservation ratios in **Table 5-13**. Preservation ratios were determined on the basis of the following factors.

- The rarity and irreplaceability<sup>13</sup> of the land cover type within the inventory area (rarer and more irreplaceable land cover types have higher ratios).
- The biological value of the land cover type (e.g., overall biological diversity, function as habitat for covered species, ecosystem function).
- Mitigation ratios previously accepted by state and federal regulatory agencies (these ratios were used as starting points for this Plan).

Avoidance and minimization of impacts on aquatic land cover types (see Chapter 6) at project sites may reduce the amount of preservation area required if preserved aquatic land cover types meet minimum distance requirements from dense urban development (see *Buffer Zones within the Reserve System* below). Note that project proponents who receive take authorization under this Plan and who wish to fill jurisdictional wetlands and waters must obtain separate permits and certification from USACE and the Regional Board, respectively, to comply with CWA Sections 404 and 401, and may also need permits from the Regional Board under the Porter-Cologne Water Quality Control Act and a streambed alteration agreement with CDFG under California Fish and Game Code Sections 1600 et seq.

## Buffer Zones within the Reserve System

### Fuel Buffers

When the Implementing Entity acquires land adjacent to existing or planned urban development<sup>14</sup> that has no buffer zone, or an inadequate buffer zone, one may be created on the reserve according to the terms described in Chapter 6, Section 6.4.6, subheading *Condition 10 Fuel Buffer*. The buffer zone will experience a reduction in habitat function due to the indirect effects of urban development (see Chapter 4). To account for this loss of habitat function, any area adjacent to development that is disked, mowed, and/or sprayed with herbicides for fuel management will not be credited toward land acquisition

<sup>13</sup> A habitat or land cover type is irreplaceable if it cannot be restored or created elsewhere due to unique soil requirements, topography, or other conditions.

<sup>14</sup> Defined as the planning limit of urban growth (see Chapter 2) or the Urban Service Area, whichever is greater.

requirements (see Chapter 6 for required fuel buffers). The remainder of any buffer zone may be credited toward terrestrial land cover because it will provide habitat for some species and serve an important function. However, aquatic land cover types and aquatic covered species breeding habitat without sufficient buffer zones will not be credited toward meeting preservation requirements because their proximity to intensive urban development can greatly reduce their habitat value. See **Table 5-15** for minimum setback distances required for aquatic land cover types to be counted toward Plan requirements for preservation and restoration or creation (**Table 5-12**).

### Plant Occurrence Buffers

In order for a plant occurrence to count as protected under the Plan, there will be a buffer of at least 500 feet between the occurrence and adverse land uses. Adverse land uses include permanent land uses that could endanger the long-term viability of the plant occurrence; including urban development, landfill, and other intensive land uses. A 500-foot buffer was recommended in the *Recovery Plan for Serpentine Soil Species of the San Francisco Bay Area* (U.S. Fish and Wildlife Service 1998c), and this same buffer has been extended to the only covered plant not restricted to serpentine soils, the Loma Prieta hoita.

This buffer may be reduced under specific circumstances where, based on documented site conditions, plant occurrences are protected from adverse land uses by another means. For example, a reduced buffer may protect the viability of a plant occurrence if a major physical barrier separates the occurrence from adjacent land use. Conversely, the buffer may need to be increased in specific circumstances where, based on documented site conditions, plant occurrences are not afforded adequate protection from adjacent land uses. For example, to minimize hydrologic effects of adjacent land use on an occurrence located down-gradient, a buffer exceeding 500 feet may be necessary. Adequacy of the 500-foot buffer will be determined by the Implementing Entity, in coordination with the Wildlife Agencies. Buffers surrounding protected plants will also expand as plant occurrences expand, assuming space is available after covered activities are completed. In other words, occurrence expansion will not result in a reduced buffer.

### Incorporating Covered Plant Species

The locations of all covered plants within the study area are not known due to survey and mapping limitations. Habitat distribution models were developed for 6 of the 9 covered plant species (see Chapter 3 and **Appendix D**), but the conservation value of these models is limited because of the paucity of known occurrences of most species in the study area. The habitat requirements of the remaining species are not well known enough to develop a credible model at this time. Many covered plants likely have unique microhabitat requirements such as soil types or plant associations that cannot be mapped at the regional scale used in this Plan.

Despite model limitations, for compliance purposes, impacts on all covered plants will be limited by known *occurrences* (**Table 4-6**) and modeled habitat for

the 6 covered plants for which habitat models were developed (**Table 4-4**) if additional occurrences are not discovered during the permit term. Similarly, mitigation and conservation will be based on known occurrences (**Tables 5-16**) and modeled habitat (**Table 5-17**). Additional known occurrences and new occurrences not yet discovered at the time of permit issuance can be impacted up to the limits described in **Table 5-16** and in accordance with the criteria described below. For all but one covered species, a plant occurrence is defined as a group of individuals that are separated by at least 0.25 mile from other groups of individuals of the same species or subspecies. This definition was used to be consistent with how plants are tracked by the CNDDB, and to facilitate compliance monitoring by the Plan (see Chapter 7). For Santa Clara Valley dudleya, a distinct occurrence is ecologically a group of individuals on a rock outcrop. These rock outcrops often occur less than 0.25 mile from each other. A different definition of an occurrence was used for this species because of its unique clumped distribution on rock outcrops.

In some cases, an occurrence may be equivalent to a population; in other cases, multiple occurrences may form a single population. A biological population is defined differently for each of the covered plants and is often unknown due to a lack of population data. Therefore, an occurrence provides a single standard by which to measure impacts and conservation for all covered plants. During implementation, the Implementing Entity may conduct monitoring or management actions based on populations, which is a more biologically meaningful unit.

The Implementing Entity must ensure that adequate numbers of occurrences of covered plants are protected in the Reserve System. The conservation strategy for each plant species includes the acquisition (preservation) and/or creation of covered plant occurrences. Both acquired and created occurrences will be permanently protected in the Reserve System. Land containing occurrences of covered plants will be acquired from willing sellers in fee title or through establishment of conservation easements.

Almost all known occurrences of covered plants in the study area are found outside the planning limit of urban growth and away from the footprint of covered activities. Therefore, many occurrences are expected to be included in the Reserve System as it is established. However in order to ensure that covered plant occurrences are protected, the land acquisition actions listed below include specific requirements for covered plants.

Preservation of covered plant occurrences must occur ahead of the impacts to each plant species, as described in the Stay-Ahead provision in Section 8.6.1 *Stay-Ahead Provision*. Impacts to all plants, with the exception of the Coyote ceanothus (see Section 5.4.11) will be offset by the acquisition of occurrences of the same species that is at least equivalent in size<sup>15</sup> and of the same or better “condition” than the impacted occurrence. The number of occurrences that must

---

<sup>15</sup> Measured as either plant cover or number of individuals, whichever is most appropriate for the species and site. The occurrence size that must be matched or exceeded is the occurrence size at the time of impact, which may be different from the known occurrence size during the development of this document.

be acquired prior to impacts will be in accordance with the Plan's species-specific mitigation ratios (**Table 5-16**). For example, although the Plan proposes to preserve 55 occurrences of Santa Clara dudleya if additional occurrences were not discovered during the permit term, four occurrences of equal or greater size and same or better condition must be acquired prior to each impact. In other words, all 55 occurrences of Santa Clara dudleya do not need to be acquired prior to the first impact. Acquisition ratios were not developed for the Tiburon Indian paintbrush, Coyote ceanothus, and Metcalf Canyon jewelflower, the three plant species for which additional impacts are not covered by the Plan even if additional occurrences are discovered during the permit term. For more details, refer to species-specific acquisition timing requirements in Section 5.4 *Benefits of and Additional Conservation Actions for Covered Species*.

If the Implementing Entity cannot protect the necessary plant occurrences, then proponents of projects that will have impacts on covered plants will be required to protect the covered plant occurrences in order to receive take authorization under this Plan for any covered species.

To ensure that the Plan adequately protects covered plants, site-specific surveys in impact areas (described in Chapter 6), and site inventories conducted in new reserves, will document the presence, absence, and condition (as defined below) of occurrences of covered plants. When known, this information will also inform the land acquisition process. Field assessments will consist of one season of surveys for all species, except when there is evidence that a single season may not provide adequate information to make a reliable assessment of condition as defined below. Reasons for a second season of surveys could include:

- Extreme weather (e.g., unusually low or high rainfall), fire, or other natural condition or disaster during the survey year that creates unusual negative or positive growing conditions.
- Disease appears to be affecting greater than 50% of an occurrence, especially of woody species.

For the purposes of this Plan, "good condition" of a covered plant occurrence is defined as a high potential to increase in size with improved management. The condition of a plant occurrence will be assessed in the field by a qualified botanist on the basis of the characteristics listed below.

- **Physical health.** Individuals in good or excellent physical health (e.g., little or no signs of disease, viruses, severe herbivory, nutrient deficiencies) are more likely to survive, achieve an average or above-average lifespan, and reproduce successfully than individuals in poor physical condition. Plants in good physical health generally also indicate a highly suitable site.
- **Age structure.** Occurrences of perennial species with an age distribution that includes many seedlings or juvenile plants relative to adults suggests a stable or positive rate of occurrence growth. Additionally, for annual and perennial species, seeds or bulbs in the soil (i.e., the seed bank) are also part of a plant occurrence's age structure, but this component is generally very difficult to assess.

- **Reproductive success.** Occurrences with evidence of average or above-average reproductive success for the species (e.g., production of flowers per plant, seed production per flower or per plant, proportion of seeds that appear to be viable based on visual observations) are more likely to be increasing than occurrences with below-average reproductive success, because this is often a key component of occurrence growth rate. If reproductive success cannot be measured, plant size or other physical features may be an appropriate surrogate in some covered species.
- **Availability of suitable habitat.** In order for a plant occurrence to remain stable or grow, enough suitable habitat must be present. Occurrences near unoccupied suitable habitat or without evidence of shrinking suitable habitat areas (e.g., nonnative plant populations that may be expanding, native shrubs that may be advancing) will be considered in better condition than occurrences without these indicators.
- **Diversity of suitable habitat.** Occurrences that occupy a wide range of microhabitats for the species may exhibit relatively high genetic diversity and therefore occurrence condition. Occurrences that occupy unusual microhabitats for the species may indicate unusual genetic composition or adaptations that should be protected.
- **Threats.** Threats to occurrences within the Reserve System will be assessed to ensure that protection and improved management will not be undermined by external factors such as disease, severe herbivory, recreational uses, or adjacent land uses. Occurrences in danger from threats that can be addressed should be considered in better condition than those that cannot be addressed.

The location of affected plant occurrences and the location of the preserved or created plant occurrences will also be taken into consideration by a qualified botanist. In some cases, it may be beneficial to preserve occurrences that would expand the current range of a species. In other cases, preservation of genetic integrity in a specific locality may have more conservation value. The Implementing Entity will consult the Wildlife Agencies on the location of preserved and created occurrences to ensure that the biological goals and objectives of each species are met.

Sites selected for preservation of plant occurrences in good condition will be incorporated into the Reserve System to ensure long-term viability of these occurrences. Reserves will contain sufficient suitable habitat for the covered plant to support occurrence expansion and fluctuation and to apply beneficial management techniques such as appropriate disturbance regimes.

When practicable, all lands protecting covered plant occurrences will be connected to existing protected areas or Habitat Plan reserves. When not practicable, the minimum reserve size to protect covered plant occurrences will be determined on the basis of site-specific conditions but will not be less than 40 acres unless acquiring a smaller site is the only way to meet a land-acquisition requirement in this Conservation Action (i.e., all other options have been exhausted). The minimum reserve size required for the long-term viability of covered plant occurrences will vary depending on species, site conditions,

occurrence status, and surrounding land uses but will generally be unknown. A 40-acre minimum has been established because it is a common parcel size in the study area (1/16 of a section) and because this is the estimated minimum size needed to properly manage a site in the study area. Because land acquired for the Reserve System must be linked to other Habitat Plan reserves or existing public lands whenever possible, few, if any, isolated, 40-acre reserves will be established. Additionally, reserves must be configured to minimize the extent of edge (e.g., rectangles, squares, or circles instead of strips or fragments).

Created occurrences will not count toward the Stay-Ahead provision for plants and will not be used to mitigate adverse effects, with the exception of the Coyote ceanothus. Created plant occurrences will therefore only contribute to species recovery due to the highly experimental nature of this technique.

## Land Acquisition Requirements by Conservation Analysis Zone

To ensure that acquisition occurs in locations that will maximize the benefits to natural communities and covered species, acquisition requirements are also defined by conservation analysis zone (**Figure 5-5**) or by a combination of zones. In addition to numeric land acquisition requirements by land cover and zone, qualitative land acquisition requirements are provided for some zones. For instance, linkage of existing public lands or preservation of covered plant occurrences could be required. The requirements for land acquisition within the zones or groups of zones are described below, generally from north to south in the study area. The relevant acquisition actions from **Table 5-2a** are also referenced.

The proposed land conservation strategy is shown in **Figure 5-7**. **Table 5-18** describes land acquisition and enhancement requirements for select conservation analysis zones where geographic specificity was required to ensure that Plan goals and objectives were met. This figure illustrates the relative level of land acquisition effort that would occur in each of the conservation analysis zone (high, moderate, or low) based on the specific land acquisition requirements described below. The landscape linkages protected or partially protected by the land conservation strategy are shown in **Figure 5-8** (linkages correspond to those in **Table 5-9** and **Figure 5-6**).

### Alameda-1 and Coyote-7

The Alameda-1 conservation analysis zone lies at the northern edge of the study area in the Alameda watershed. This zone is combined with the adjacent Coyote-7 zone for the purposes of the land acquisition strategy because together they create an important linkage outside the study area. In addition, land cover types and species habitat in the two zones are similar. The primary purposes of the land acquisition strategy in these conservation analysis zones are listed below.

- Enhance connectivity and linkage between large blocks of existing open space in the northeast corner of the study area and the large network of existing open space adjacent to the study area to the north (Linkage 4 in **Table 5-9** and **Figure 5-8**) (LAND-L7).
- Protect large stands of valley oak woodland (LAND-OC3).
- Protect stands of northern coastal scrub/Diablan sage scrub (LAND-C3).
- Protect upper watershed tributaries of Upper Penitencia Creek (important breeding habitat for foothill yellow-legged frog) and Cherry Flat Reservoir (LAND-L1, LAND-R5).
- Protect an area with a high density of ponds and likely breeding habitat for California red-legged frog, California tiger salamander, and western pond turtle (LAND-G2, LAND-OC1, LAND-OC2, LAND-OC3, LAND-OC4, LAND-OC5, LAND-WP3a, LAND-WP3b, LAND-WP6a, LAND-WP6b).
- Protect designated critical habitat for California red-legged frog and California tiger salamander (LAND-WP4).
- Protect elevation gradients in the north of the study area under threat from rural residential development (LAND-L2a, LAND-L2b, LAND-L-2c, LAND-L2d).

Land acquisition in these conservation analysis zones will expand the existing open space in the northeast corner of the study area and provide an important linkage to more than 75,000 acres of contiguous protected areas to the north in Santa Clara and Alameda Counties. Acquisition in this area also provides a unique opportunity to protect extensive stands of valley oak woodland, critical habitat for three covered species, and elevation gradients, all with moderate amounts of acquisition. Acquired lands are expected to have excellent potential for freshwater marsh restoration and pond creation.

The specific land acquisition requirements for these conservation analysis zones are shown below.

- Acquire natural land cover types in the two conservation analysis zones as shown in **Table 5-18**.
- Land must be acquired to connect existing open space adjacent to the conservation analysis zones to the north and south.
- The landscape linkage between the study area and SFPUC lands to the northwest must be widened to at least 1.0 mile.

### Guadalupe-1 and -3

Guadalupe-3 is one of the largest conservation analysis zones in the study area. However, this zone is largely composed of urban development in San José. The southern edge of Guadalupe-3 supports small but important patches of serpentine grassland, including the north side of Tulare Hill. Guadalupe-1 is combined with Guadalupe-3 for the purposes of the land acquisition strategy because of the

similar land cover types found along their borders. The primary purposes of the land acquisition strategy in these conservation analysis zones are listed below.

- Link large block of protected lands south of Calero Reservoir with Almaden Quicksilver County Park and extensive protected lands outside the study area to the west in the Santa Cruz Mountains (Linkage 9 in **Table 5-9** and **Figure 5-8**) (LAND-L8).
- Complete the linkage between the Diablo Range and the Santa Cruz Mountains across Tulare Hill (Linkage 8 in **Table 5-9** and **Figure 5-8**) (LAND-L4, LAND-WP7).
- Protect and enhance important stands of serpentine grassland and serpentine chaparral (LAND-C2).
- Protect and enhance watershed functions in the Guadalupe Watershed (LAND-L3).
- Protect stands of northern coastal scrub/Diablan sage scrub (LAND-C3).
- Protect freshwater perennial marsh and seasonal wetlands (LAND-WP1a, LAND-WP1b, LAND-WP2a, LAND-WP2b).
- Protect important occurrences and suitable habitat of covered plants, including Mt. Hamilton thistle, Metcalf Canyon jewelflower, most beautiful jewelflower, smooth lessingia, and Santa Clara Valley dudleya (LAND-P2, LAND-P3, LAND-P4, LAND-P5, LAND-P6, LAND-P7, LAND-P10).
- Protect important habitat and designated critical habitat for Bay checkerspot butterfly (LAND-G3).
- Partner with various public agencies in north San José (e.g., San José Water Pollution Control Plant, VTA) to protect and maintain the second largest population of western burrowing owls in the study area (LAND-G6).
- Protect the watershed of Alamitos Creek and its tributaries (LAND-R5).

Land acquisition in these conservation analysis zones achieve multiple goals and objectives with relatively low levels of land acquisition. First, many occurrences of covered plants can be protected and possibly enhanced with strategic acquisitions. Second, important potential habitat for Bay checkerspot butterfly would be acquired so that improved management can attract butterflies and expand their range locally.

Finally, key acquisitions can also provide important linkages among the existing network of open space in and adjacent to the study area. These acquisitions can also serve as important buffers between existing and future urban areas and extensive open space in the Santa Teresa Hills and Santa Cruz Mountains.

The land acquisition requirements for these conservation analysis zones are listed below.

- Acquire serpentine grassland within the conservation analysis zones as shown in **Table 5-19**.

- Protect and enhance occupied and potential nesting habitat for western burrowing owl consistent with the burrowing owl conservation strategy described in Section 5.4.6 *Western Burrowing Owl*.
- Acquire at least 1,600 acres in the Guadalupe Watershed as a whole.
- Link Santa Teresa and Calero County Parks.

## Coyote-4

Conservation analysis zone Coyote-4 comprises much of the upper watershed of Coyote Creek above Anderson Reservoir (**Figure 5-5**), including some of San Felipe Creek and its tributaries, as well as a portion of Coyote Ridge. The primary purposes of the land acquisition strategy in this conservation analysis zone are listed below.

- Provide landscape linkage between Coyote Ridge and mid- to high-elevation natural communities in the Diablo Range (Linkage 7 in **Table 5-9** and **Figure 5-8**).
- Protect linkage between J. Grant Park and Henry Coe (Linkage 5 in **Table 5-9** and **Figure 5-8**)
- Protect and enhance important stands of valley oak and blue oak woodland (LAND-OC3), mixed oak woodland and forest (LAND-OC1), and annual grassland (LAND-G2).
- Protect and enhance watershed functions in the Coyote Watershed (LAND-L3).
- Protect stands of northern coastal scrub/Diablan sage scrub (LAND-C3).
- Protect and enhance riparian forest along lower San Felipe Creek and its tributaries (LAND-R2, LAND-R5).
- Protect and enhance potential nesting and overwintering habitat for western burrowing owl, and potential breeding and foraging habitat for tricolored blackbird.
- Protect and enhance potential breeding habitat and extensive upland habitat for covered amphibians and western pond turtle (LAND-G2, LAND-OC1, LAND-OC2, LAND-OC3, LAND-OC4, LAND-OC5, LAND-WP3a, LAND-WP3b, LAND-WP5, LAND-WP6a, LAND-WP6b).
- Protect and enhance annual grasslands that support or could support California ground squirrels to provide food and shelter for covered and native species (LAND-G8).
- Protect freshwater perennial marsh and seasonal wetlands (LAND-WP1a, LAND-WP1b, LAND-WP2a, LAND-WP2b).
- Protect designated critical habitat for California tiger salamander.

This conservation analysis zone is noteworthy because of its relatively high concentration of desirable land cover types: blue oak woodland, valley oak

woodland, riparian woodland (including high quality sycamore alluvial woodland) and forest, and ponds. Moreover, these areas are largely unsurveyed and may contain important undocumented occurrences of covered plants. Covered wildlife species known or with potential to occur in this area are California red-legged frog, California tiger salamander, western pond turtle, and foothill yellow-legged frog; extensive habitat for these species occurs in this conservation analysis zone. Acquisition in this zone would also support a large proportion of the annual grassland in the Reserve System. These lands may also support secluded rock outcrops or large trees overlooking open grassland that would protect suitable nesting sites for golden eagle and other raptors.

The land acquisition requirements for this conservation analysis zone are listed below.

- Acquire natural land cover types in conservation analysis zone as shown in **Table 5-18**.
- Acquire serpentine grassland within the conservation analysis zones as shown in **Table 5-19**.
- Provide landscape linkage along Coyote Ridge between Anderson Lake County Park and the Silver Creek Hills (Linkage 6 in **Table 5-9** and **Figure 5-8**).
- Connect Coyote Ridge with the San Felipe Ranch Conservation Easement.

In 2008, creation of the San Felipe Ranch Conservation Easement protected all of the remaining unprotected ponderosa pine woodland in the study area. Therefore, no ponderosa pine woodland is available to protect in the Reserve System. There is also no impact expected to this land cover type.

## Coyote-5 and 6

Conservation analysis zone Coyote-5 encompasses the southern end of the Coyote watershed and the southern half of Coyote Ridge (**Figure 5-5**). Because this subwatershed spans Coyote Valley, it also includes the eastern extent of the Santa Teresa Hills and the lower foothills of the Santa Cruz Mountains west of Coyote Valley. Coyote-6 encompasses the northern half of Coyote Ridge and the immediate watershed of Silver Creek. The main stem of Coyote Creek below Anderson Dam is excluded from the conservation analysis zone because it occurs within several County parks. These conservation analysis zones were combined for the purposes of the land acquisition strategy because together they include all of Coyote Ridge and support most of the unprotected serpentine grassland in the study area. The primary purposes of the land acquisition strategy in these conservation analysis zones are listed below.

- Provide landscape linkage across Coyote Ridge (Linkage 6 in **Table 5-9** and **Figure 5-8**).
- Enhance the landscape linkage from Coyote Ridge to Coyote Creek, facilitating connections across the Santa Clara Valley (Linkages 8 and 10 in **Table 5-9** and **Figure 5-8**).

- Protect and enhance watershed functions in the Coyote Watershed (LAND-L3).
- Provide a connection from Santa Teresa County Park to Calero County Park.
- Protect and enhance extensive serpentine grassland and serpentine chaparral along Coyote Ridge (LAND-L5, LAND-C2).
- Protect and enhance extensive occupied habitat for Bay checkerspot butterfly and designated critical habitat (LAND-G3).
- Protect freshwater perennial marsh and seasonal wetlands (LAND-WP1a, LAND-WP1b, LAND-WP2a, LAND-WP2b).
- Protect and enhance occurrences of and suitable habitat for covered plants including Mt. Hamilton thistle, Metcalf Canyon jewelflower, most beautiful jewelflower, smooth lessingia, fragrant fritillary, Loma Prieta hoita, Coyote ceanothus, and Santa Clara Valley dudleya (LAND-P1, LAND-P2, LAND-P3, LAND-P5, LAND-P6, LAND-P7, LAND-P8, LAND-P11).
- Protect and enhance annual grasslands that support or could support California ground squirrels to provide food and shelter for covered and native species (LAND-G8), including overwintering habitat for western burrowing owl.
- Protect and enhance upland habitat near and adjacent to Laguna Seca, a future wetland restoration site, for covered species that breed in coastal and valley freshwater marsh (e.g., tricolored blackbird, California tiger salamander, California red-legged frog, and western pond turtle).
- Protect upland habitat connections to Coyote Creek below Anderson Dam, an important regional wildlife linkage (Linkage 10 in **Table 5-9** and **Figure 5-8**).

Land acquisition in these two conservation analysis zones will protect and provide the opportunity to enhance 73% of the remaining suitable and occupied habitat for Bay checkerspot butterfly in Coyote-5 and Coyote-6. Land acquisition in these zones is essential to meeting the conservation objectives for this species. Serpentine grassland and chaparral in these zones also support at least eight covered plant species, sometimes in multiple occurrences; accordingly, conservation in these zones is essential to meeting the plant conservation requirements. To meet the plant conservation targets, serpentine grassland will be acquired on both sides of the Santa Clara Valley, protecting occurrences that may be disjunct from one another. Much of the serpentine chaparral in the Reserve System would be acquired in these zones.

Land acquisition in these conservation analysis zones would also protect and provide opportunities to enhance upland habitat near Laguna Seca. Historically, this large wetland complex was unique in the Santa Clara Valley, supporting a large freshwater marsh and large willow groves (San Francisco Estuary Institute 2006). This wetland complex will be restored by SCVWD to some of its historic condition in conjunction with the approved Coyote Valley Research Park development.

The valley floor between Tulare Hill and Anderson Reservoir is one of the narrowest points in the Santa Clara Valley between the Santa Cruz Mountains and the Diablo Range (Linkages 8, and 10 in **Table 5-9** and **Figure 5-8**). The land acquisition strategy in Coyote-5 focuses on protecting lands east and west of Coyote Creek to allow terrestrial and aquatic wildlife to continue to access and use that creek as a movement corridor (portions of both sides of the creek are already protected by County Parks). Additional land acquisition in the Coyote Valley could occur, but it is not required. As development intensifies on the valley floor in this zone west of the creek, Coyote Creek will increasingly become the primary corridor for terrestrial wildlife moving through the valley.

At least 24 undercrossings or culverts have been documented along this stretch of U.S. 101, most of which are small culverts associated with drainages from Coyote Ridge (though at least one is approximately 6 feet in diameter) (California Department of Fish and Game 2006). There are also two large underpasses that allow wildlife passage under U.S. 101. Many species of wildlife have been documented using these culverts recently, and most of the culverts are utilized by multiple species (T. Diamond pers. comm.). Of the 24 culverts along this stretch of U.S. 101, 19 have Type 1, 2, or 3 open space on both sides of the highway; the remaining five culverts have Type 1, 2, or 3 open space only on the west side of the highway (Coyote Creek Parkway, a County park). The land acquisition strategy in Coyote-5 targets protection of land that provides access to most of the remaining culverts. Management actions within the Reserve System could then focus on enhancing these corridors, as indicated by pre-acquisition assessments and targeted studies. The conservation strategy also includes actions to assess and improve wildlife connectivity in these conservation analysis zones; see Section 5.3.2 *Landscape Conservation and Management* subheading *Connectivity and Permeability*.

The land acquisition requirements for these conservation analysis zones are listed below.

- Acquire serpentine grassland within the conservation analysis zones as shown in **Table 5-19**. Serpentine grassland acquisition must occur on both sides of the Santa Clara Valley.
- Provide linkage between Santa Teresa County Park and Calero County Park.
- Protect at least 50 acres of serpentine grassland east of Santa Teresa County Park.
- Acquire the unprotected portions of the three unprotected occurrences of Coyote ceanothus within Coyote-5.
- Acquire either Kalana 1 or Kalana 2, 3, and 4 populations of Bay checkerspot butterfly (see **Table 5-7** and the species account in **Appendix D**) to protect and enhance habitat for Bay checkerspot butterfly.
- Acquire at least 75% of the currently unprotected portions of mapped habitat for Bay checkerspot butterfly at the Hale and Falcon Crest sites within Coyote-5 and Llagas-3 (see habitat map in species account in **Appendix D**).

## Llagas-3

Conservation analysis zone Llagas-3 comprises the northern half of the Llagas Basin subwatershed downstream of Chesbro Reservoir, mostly on the floor of the Santa Clara Valley. This zone includes the city of Morgan Hill and extensive agricultural areas of the valley. It also includes small but important patches of serpentine grassland and riparian woodland. The primary purposes of the land acquisition strategy in this conservation analysis zone are listed below.

- Protect and enhance habitat for Bay checkerspot butterfly on the west side of the Santa Clara Valley (LAND-G3).
- Protect and enhance potential breeding and overwintering habitat for western burrowing owl.
- Protect and enhance the largest population of Coyote ceanothus on the west side of the Santa Clara Valley (LAND-P1).
- Protect designated critical habitat for California tiger salamander (LAND-WP6b, LAND-WP1a, LAND-WP1b, LAND-WP2a, LAND-WP2b).
- Protect occurrences of and suitable habitat for covered plants, including most beautiful jewelflower, Santa Clara Valley dudleya, and smooth lessingia (LAND-P2, LAND-P5, LAND-P7, LAND-P10).
- Provide riparian restoration opportunities along Llagas Creek for least Bell's vireo and other native songbirds (LAND-R2).

Land acquisition on the west side of the Santa Clara Valley within Llagas-3 is essential to meeting the biological objectives for protection of known populations of Bay checkerspot butterfly and Coyote ceanothus. Land acquisition in this area is also important to meeting several plant acquisition targets. Llagas-3 shares conservation targets with Llagas-4 and Uvas-2 for acquisition of critical habitat for California tiger salamander northwest of Gilroy. This area also supports extensive seasonal wetlands and has been proposed as a conservation and wetland mitigation bank (WRA Environmental Consultants 2008).

Land acquisition and riparian/stream restoration along middle Llagas Creek and Little Llagas Creek within Llagas-3 and 4 were considered but rejected. Much of the narrow Llagas Creek is already owned by SCVWD, but the restoration potential is limited by several factors. First, the creek is highly channelized and would therefore require extensive physical modification that may not be feasible in consideration of surrounding lands uses and small parcels. Second, as urban development in Gilroy expands to the east, the habitat value of Llagas and Little Llagas Creeks will diminish. Finally, one of the covered activities in this Plan is a flood protection project along Llagas Creek. While that project will be built to minimize adverse effects on wildlife and habitat, its increasing use as a flood conveyance facility limits its dual use as habitat for covered species. For these reasons, land acquisition and stream and riparian restoration was instead directed to stream reaches with greater potential for enhancement of stream and riparian functions such as Uvas Creek, Carnadero Creek, Lower Llagas Creek, the Pajaro River, and Pacheco Creek.

The land acquisition requirements for this conservation analysis zone are listed below.

- Acquire land in Llagas-3 to fully protect the occurrence of Coyote ceanothus found in this zone.
- Acquire serpentine grassland within the conservation analysis zones as shown in **Table 5-19**.
- Acquire at least 75% of the currently unprotected portions of mapped habitat for Bay checkerspot butterfly at the Hale and Falcon Crest sites within Llagas-3 and Coyote-7 (see habitat map in species account in **Appendix D**).

## Llagas-4

Conservation analysis zone Llagas-4 encompasses the southern half of the Llagas Basin, mostly on the floor of the Santa Clara Valley. For convenience, this zone also includes the northern edge of the adjacent watershed that extends into San Benito County (**Figure 5-5**). The primary purpose of the land acquisition strategy in this conservation analysis zone is to protect designated critical habitat for California tiger salamander (LAND-WP6b, LAND-WP1a, LAND-WP1b, LAND-WP2a, LAND-WP2b).

Llagas-4 shares conservation targets with Llagas-3 and Uvas-2 for acquisition of critical habitat for California tiger salamander northwest of Gilroy. This area also supports extensive seasonal wetlands and has been proposed as a conservation and wetland mitigation bank (WRA Environmental Consultants 2008). See Llagas-3 for a discussion of why land acquisition along Llagas and Little Llagas Creek was not a priority within Llagas-3 and 4. There are no specific land acquisition requirements in Llagas-4.

## Pescadero-1

Conservation analysis zone Pescadero-1 is located at the southwest corner of the study area and encompasses all of the Pescadero watershed within the study area. This conservation analysis zone includes most of the headwaters of Pescadero Creek. The primary purposes of the land acquisition strategy in this conservation analysis zone are listed below.

- Protect the headwaters and streams of the Pescadero Creek watershed (LAND-L1, LAND-L3, LAND-R5).
- Protect and maintain high-quality redwood forest (LAND-OC6).
- Protect large stands of northern coastal scrub/Diablan sage scrub (LAND-C3) and annual grassland (LAND-G2).
- Protect and maintain high-quality riparian woodland in Pescadero Creek (LAND-R2).

- Facilitate the landscape linkage from the study area to the Lomerias Muertas Range (Linkage 19 in **Table 5-9** and **Figure 5-8**) and to the Gabilan Range (Linkage 20) (LAND-L19).
- Protect a portion of the linkage along the ridgeline of the Santa Cruz Mountains (Linkage 13).
- Protect and enhance habitat for California red-legged frog and western pond turtle in the Santa Cruz Mountains (LAND-WP5, LAND-WP6a, LAND-WP6b).
- Protect strong environmental gradients within the Santa Cruz Mountains (LAND-L2a, LAND-L2b, LAND-L2c, LAND-L2d).

In most years stream flow in Pescadero Creek is low, and some reaches are likely to be intermittent or dry. In wet years, most reaches along Pescadero Creek are flowing and are bordered by dense riparian forest that provides ample shade and in-stream woody debris that create pools for rearing and sheltering native fish, including juvenile steelhead. In-stream ponds and off-stream seasonal wetlands and ponds in this watershed likely provide habitat for California red-legged frog, California tiger salamander, and western pond turtle (H.T. Harvey & Associates 2006). The Pescadero watershed also supports stands of redwood forest, some of which may be unlogged.

Land acquisition in this watershed will protect large stands of riparian woodland and potential breeding habitat for least Bell's vireo, along with diverse land cover types in the southern Santa Cruz Mountains that range from California annual grassland to redwood forest to valley oak woodland. These lands may also support secluded rock outcrops or large trees overlooking extensive stands of annual grassland that would provide suitable nesting sites for raptors.

## Uvas-1, 2, 5, and 6

All the conservation analysis zones in the Uvas watershed are combined for the purposes of the land acquisition strategy. The primary purposes of the land acquisition strategy in these conservation analysis zones are listed below.

- Protect headwaters of tributaries of Uvas Creek (LAND-L1, LAND-R5).
- Protect stands of northern coastal scrub/Diablan sage scrub (LAND-C3).
- Protect freshwater perennial marsh (LAND-WP3, LAND-WP1a, LAND-WP1b).
- Protect and enhance breeding habitat for California red-legged frog and western pond turtle in the Santa Cruz Mountains (LAND-WP5, LAND-WP6a, LAND-WP6b).
- Facilitate the landscape linkage from the study area to the Lomerias Muertas Range (Linkage 19 in **Table 5-9** and **Figure 5-8**) and to the Gabilan Range (Linkage 20) (LAND-L9).

- Protect a portion of the linkage along the ridgeline of the Santa Cruz Mountains (Linkage 13 in **Table 5-9** and **Figure 5-8**).
- Protect strong environmental gradients within the Santa Cruz Mountains (LAND-L2a, LAND-L2b, LAND-L2c, LAND-L2d).
- Protect and enhance watershed functions in the Uvas Watershed (LAND-L3).
- Protect stands of northern mixed chaparral (LAND-C1) and annual grassland (LAND-G2).
- Protect riparian woodland and opportunities for riparian woodland restoration along Uvas/Carnadero Creek and the linkage along the creek (Linkage 12) (LAND-R2, LAND-R5).

Land acquisition is planned above Uvas Reservoir to protect high-quality habitat for foothill yellow-legged frog, riparian woodland, and a relatively high diversity of natural communities with a relatively low intensity of rural development in the watershed. Land cover types above Uvas Reservoir include serpentine chaparral, blue oak woodland, foothill pine-oak woodland, and valley oak woodland. Land acquisition above Uvas Reservoir has the potential to create an unbroken landscape linkage from Uvas Reservoir to Santa Teresa County Park. Land acquisition in the Uvas watershed conservation analysis zones will also support populations of California red-legged frog and California tiger salamander in the Santa Cruz Mountains to ensure that populations on either side of the Santa Clara Valley are protected and managed.

The land acquisition requirements for these conservation analysis zones are listed below.

- Protect natural land cover types within the conservation analysis zones as shown in **Table 5-18**.
- Extend the Uvas Creek Park Preserve 1.6 miles upstream to Hecker Pass Highway (LAND-R1) and setback expected development adjacent to this stream segment consistent with the stream setback condition (see Chapter 6) to protect the Uvas Creek Corridor<sup>16</sup>.
- Protect at least 1.0 mile of Uvas Creek above Uvas Reservoir to protect and enhance habitat for foothill yellow-legged frog and California red-legged frog.

## Llagas-2

Conservation analysis zone Llagas-2 occurs around and upstream of Chesbro Reservoir and borders the eastern edge of the Cañada del Oro Open Space Preserve. The primary purposes of the land acquisition strategy in this conservation analysis zone are listed below.

- Protect riparian woodland in upper Llagas Creek (LAND-R5).

<sup>16</sup> This conservation action is consistent with Goals 5-5, 5-7, and 5-8 of the approved City of Gilroy Hecker Pass Specific Plan (City of Gilroy 2005).

- Protect occupied habitat for foothill yellow-legged frog in upper Llagas Creek.
- Protect and enhance serpentine grassland and serpentine chaparral (LAND-G1, LAND-C2).
- Protect stands of northern coastal scrub/Diablan sage scrub (LAND-C3).
- Protect and enhance breeding habitat for California red-legged frog and California tiger salamander in the Santa Cruz Mountains (LAND-WP1a, LAND-WP1b, LAND-WP2a, LAND-WP2b).
- Protect riparian habitat along upper Llagas Creek for least Bell's vireo and other native songbirds and provide riparian restoration opportunities (LAND-R2).
- Protect potential habitat for Bay checkerspot butterfly (LAND-G3).

Land acquisition in this conservation analysis zone serves multiple purposes. Some of the only known occupied habitat for foothill yellow-legged frog in the Santa Cruz Mountains in the study area is present upstream of Chesbro Reservoir (H.T. Harvey & Associates 1999). The conservation strategy includes stream protection along upper Llagas Creek to protect this habitat and provide opportunities for habitat enhancement, as indicated by pre-acquisition assessments and targeted studies and informed by the monitoring and adaptive management program. Furthermore, potential habitat for Bay checkerspot butterfly (Cañada Garcia site) and serpentine covered plants are also found in this conservation analysis zone. Because surveys have not been conducted in this area, the occurrence of serpentine covered species is largely unknown. This conservation analysis zone also supports small patches of serpentine chaparral.

The land acquisition requirements for this conservation analysis zone are listed below.

- Acquire serpentine grassland within the conservation analysis zones as shown in **Table 5-19**.
- Acquired land that will connect with either protected lands around Chesbro Reservoir or the Open Space Authority lands within the analysis zone.
- Acquire at least 1.0 mile of Llagas Creek above Chesbro Dam to protect and enhance habitat for foothill yellow-legged frog, California red-legged frog, and least Bell's vireo.

## **Pacheco-1, 2, 3, 4, 5, and 6**

Conservation analysis zones Pacheco 1–6 encompass the upper and middle reaches of Pacheco Creek and its tributaries (e.g., south and north forks of Pacheco Creek). These conservation analysis zones are characterized by large, remote ranches with grassland, oak woodland, and chaparral at a variety of elevations and terrain. Extensive tracts of riparian woodlands are found in several zones along Pacheco Creek and its major tributaries. These zones are combined for the purposes of the land acquisition strategy because of their

similar land cover types and species habitat, and the overlapping land ownership patterns among the zones. The primary purposes of the land acquisition strategy in these conservation analysis zones are listed below.

- Protect and enhance riparian woodland, including large stands of sycamore alluvial woodland, along the main stem and tributaries of Pacheco Creek, and provide restoration opportunities in this area (LAND-R2).
- Protect potential breeding habitat for least Bell's vireo (LAND-R5).
- Protect portions of landscape linkage along Pacheco Creek (Linkage 17 in **Table 5-9** and **Figure 5-8**) (LAND-L1).
- Maintain landscape linkages across SR 152 at key undercrossings or gaps in the highway median barrier (Linkage 15 in **Table 5-9** and **Figure 5-8**) for San Joaquin kit fox and other native species.
- Protect and enhance watershed functions in the Coyote and Pacheco Watersheds (LAND-L3).
- Protect movement and potential breeding habitat for San Joaquin kit fox (LAND-G9).
- Protect and enhance extensive stands of annual and potential native grasslands (LAND-G2, LAND-G3) that support or could support California ground squirrels to provide food and shelter for covered and other native species (LAND-G5, LAND-G8).
- Protect strong environmental and elevation gradients (LAND-L2a, LAND-L2b, LAND-L2c, LAND-L2d).
- Protect large stands of northern mixed chaparral (LAND-C1), mixed oak woodland and forest (LAND-OC1), and valley oak woodland (LAND-OC3).
- Protect and enhance breeding and upland habitat for covered amphibians and reptiles (LAND-G2, LAND-OC1, LAND-OC2, LAND-OC3, LAND-OC4, LAND-OC5, LAND-WP5, LAND-WP6a, LAND-WP6b).

Land acquisition in these conservation analysis zones will protect important stands of riparian woodland and scrub, valley oak woodland, and northern mixed chaparral. Riparian woodland along Pacheco Creek may provide suitable breeding habitat for least Bell's vireo. These lands may also support secluded rock outcrops or large trees overlooking open grassland that would provide suitable nesting sites for golden eagle and other raptors. In addition, the low-elevation annual grassland and some oak woodland types are suitable for movement of San Joaquin kit fox through the study area to known breeding sites at the fringes of the inner Coast Ranges to the east and south of the county. Acquisition of low-slope grassland in this area may also provide suitable breeding habitat for San Joaquin kit fox, although such events are expected to be rare.

Land acquisition in these conservation analysis zones will also protect a landscape linkage within the Diablo Range (Linkage 15) that will benefit several covered and other native species such as San Joaquin kit fox, Tule elk, and mountain lion. Because the threat of development in these zones is low, land

acquisition in these zones is targeted, in part, at key points along SR 152 where kit fox and other native wildlife are most likely to cross the busy road. SR 152 between Gilroy and the Santa Clara/Merced county line poses a major hazard and a partial barrier to wildlife movement. In addition to the large and increasing volume of traffic, a 6-mile-long median barrier stretches from Bell Station to the Santa Clara/Merced County line. There are only three breaks in this barrier, each about 50 feet wide. Because these breaks are so narrow and few, and because of the high volume of traffic on the road, undercrossings are very important to maintain a landscape linkage across the road.

There are six bridges that span creeks along SR 152 and offer connectivity along the stretch with the median barrier (**Figure 5-8**). The riparian corridors are well vegetated, and the bridge spans offer adequate clearance for all species to move underneath. There are no data of wildlife use of these undercrossings, but the habitat model for San Joaquin kit fox (**Appendix D**) suggests this area as a potential regional linkage. The land acquisition strategy in these zones will preserve key undercrossings along SR 152. The conservation strategy also includes actions to assess and improve wildlife connectivity in these conservation analysis zones; see Section 5.3.2 *Landscape Conservation and Management* subheading *Connectivity and Permeability*.

The land acquisition requirements for these conservation analysis zones are listed below.

- Land acquisitions in these conservation analysis zones will occur as shown in **Table 5-18**.
- Land will be acquired on either side of SR 152 at two key crossing points to protect and provide opportunities to enhance wildlife movement across the road.
- Protect at least 1.0 mile of the main stem of Pacheco Creek, North Fork of Pacheco Creek below Pacheco Dam, or South Fork Pacheco Creek.
- Protect land in the Pacheco Creek Watershed giving higher priority to lands with gentler slopes that provide suitable habitat for San Joaquin kit fox.

## **Pacheco-7 and -8, Coyote-2**

Although they are in different watersheds, Pacheco-7, Pacheco-8, and Coyote-2 serve a similar function because they represent the closest connection between Henry W. Coe State Park and the extensive wetland complex across the county line in San Benito County (San Felipe and Soap Lakes). These conservation analysis zones are also combined for the purposes of the land acquisition strategy because of their similar patterns of land ownership and parcel configuration. The primary purposes of the land acquisition strategy in these conservation analysis zones are listed below.

- Link Henry W. Coe State Park with the San Felipe Lake (Soap Lake) region in San Benito County (Linkage 14 in **Table 5-9** and **Figure 5-8**) (LAND-L6).

- Protect immediate watershed of San Felipe Lake.
- Protect riparian woodland and streams in upper Coyote Creek and Pacheco Creek (LAND-L1, LAND-R2), including large stands of sycamore alluvial woodland.
- Protect freshwater perennial marsh (LAND-WP1a, LAND-WP1b).
- Protect and enhance high density of ponds to support covered amphibians and reptiles and other native species, and possibly tricolored blackbird (LAND-G2, LAND-OC1, LAND-OC2, LAND-OC3, LAND-OC4, LAND-OC5, LAND-WP5, WP3a, LAND-WP3b, LAND-WP5, LAND-WP6a, LAND-WP6b).
- Protect designated critical habitat for California tiger salamander.
- Protect movement and potential breeding habitat for San Joaquin kit fox (LAND-G9).
- Protect and enhance annual grasslands (LAND-G2) that support or could support California ground squirrels to provide food and shelter for covered and other native species (LAND-G5, LAND-G8).
- Protect foraging habitat for birds using the large wetland complex surrounding San Felipe Lake, including tricolored blackbird.
- Protect strong environmental gradients in the study area (LAND-L2a, LAND-L2b, LAND-L2c, LAND-L2d).
- Protect and enhance valley oak woodland (LAND-OC3).

The land acquisition strategy in these conservation analysis zones focuses on protection of environmental gradients, habitat for covered amphibians, and an important landscape linkage. This area has an unusually high density of ponds compared to the rest of the study area; accordingly, it provides excellent potential breeding sites for California red-legged frog, California tiger salamander, western pond turtle, and possibly tricolored blackbird. With enhancement, this dense network of ponds could support a large population of these covered species. These conservation analysis zones, particularly Pacheco-8, also provide an important connection over a wide range of environmental gradients between Henry W. Coe State Park and the large wetland complex in Soap Lake, including San Felipe Lake. Land within Pacheco-8 provides the most direct connection between this wetland complex and the vast area of annual grassland and oak woodland in the Diablo Range foothills; consequently, Pacheco-8 may be important for terrestrial wildlife moving from the Santa Clara Valley to the Diablo Range. In addition, aquatic species breeding at San Felipe Lake (e.g., tricolored blackbird) likely forage in upland habitats nearby; land within these conservation analysis zones provides the closest upland foraging habitat to San Felipe Lake. This area also provides the “gateway” from the Diablo Range to Linkage 18 along the Pajaro River. Large stands of valley oak woodland and riparian sycamore alluvial woodland are also found within these conservation analysis zones.

The land acquisition requirements for these conservation analysis zones are listed below.

- Land acquisitions in these conservation analysis zones will occur as shown in **Table 5-18**.
- Protect land that connects Henry W. Coe State Park to SR 152 (and San Felipe Lake in adjacent San Benito County).
- Protect at least 1.0 mile of the main stem of Pacheco Creek.

## Conservation Analysis Zones without Requirements

There are no specific land acquisition requirements in the following conservation analysis zones.

- San Tomas-1. This zone is highly urbanized at the western edge of the study area, entirely within San José. There is almost no natural vegetation left in this zone, and the creeks running through it do not provide habitat for any of the covered species.
- Guadalupe-2. This zone is also highly urbanized (84%) and provides only small, fragmented habitat for the covered species. Much of what remains is already in open space designations.
- Coyote-1 and 3. These remote and rugged conservation analysis zones are adjacent to the north and west side of Henry W. Coe State Park. There are limited acquisition opportunities in the zone due to the low number of large parcels. Development potential in this zone is very low due to steep topography, little or no access, and a lack of surface water. The few parcels occurring in these zones are expected to be acquired by State Parks as part of the expansion of Henry W. Coe State Park. Because State Parks is not a permittee in this Plan, land acquisition targets were not established in these zones.
- Coyote-8, 9, and 10. These conservation analysis zones have a relatively high degree of parcelization and urban and rural development, making conservation in these zones challenging. Coyote-10 is almost entirely within the urban service area for San José and is highly urbanized. Coyote-8 and 9 have limited conservation opportunities because of the high degree of rural development. Land acquisition or long-term management agreements within Coyote-10 (and possibly Coyote-8 and 9) will occur to protect and enhance breeding habitat for western burrowing owl consistent with the burrowing owl conservation strategy described in Section 5.4.6 *Western Burrowing Owl*.
- Llagas-1 and 5. These zones are small (Llagas-1 = 3,092 acres; Llagas-5 = 4,129 acres), support only small amounts of high-priority land cover types, and have a high proportion of small parcel sizes, making land acquisition in these zones inefficient.

- Uvas-3 and 4. Similar to Llagas-1 and 5, these zones are small (Uvas-3 = 5,061 acres; Uvas-4 = 4,422 acres). They support only small amounts of high-priority land cover types.

Despite the lack of specific land acquisition requirements in these zones, there are still portions of some of these zones that can contribute to the goals of the Plan. Any land acquired within zones Coyote-3, Coyote-8, or Coyote-9 will count towards the overall land cover requirements for the study area (**Table 5-11**). Acquisition of streams in Coyote-10 may also count towards overall stream acquisition requirements and acquisition of habitat for western burrowing owl in this zone will contribute to goals for this species.

## Acquisition of Habitat for Covered Wildlife Species

The land acquisition requirements for land cover types, by geographic locations (e.g., by Conservation Analysis Zones), and for landscape linkages, combined with the reserve assembly principles will allow the Implementing Entity to create a Reserve System that will conserve the covered species. This will occur through preservation, management, and enhancement, and in some cases, restoration, of suitable habitat for the covered species. Although the Plan is not based on field verification of suitable habitat, we have inferred the location of suitable habitat through a combination of the species models (**Appendix D**), locations of designated critical habitat (for some species), extensive data on species observations, and the expert opinion of field biologists familiar with the covered species and the study area. As a result, we are confident that the Reserve System as designed will adequately conserve the covered species.

Requirements to permanently protect plant occurrences will ensure that the covered plants will be conserved by the Plan. The Wildlife Agencies require additional assurances to guarantee that the Implementing Entity will protect habitat for the covered wildlife species and not just land cover types that are assumed to support their habitat. Furthermore, assurances are needed that the Reserve System will support habitat that is occupied by the covered wildlife species. The following requirements are included in the Plan to address these regulatory needs. All of the additional requirements below are additive to the other land acquisition requirements in the Plan.

## Acquisition of Modeled Habitat for Covered Species

To address the need to acquire habitat for the covered species and not just land cover types, the Implementing Entity will acquire land with modeled habitat for each covered species for which models were developed in the minimum amounts specified in **Table 5-17**. Commitments are provided both for new land acquired for the Reserve System and land incorporated into the Reserve System from existing open space. The commitments are to acquire minimum amounts of *modeled habitat* based on the species models in **Appendix D**.

Species models will be updated during implementation based on new information. Modeled habitat requirements will be tracked based on the most recent model update. The Implementing Entity will be conducting field inventories of new reserve lands to locate, quantify, and assess the quality of suitable habitat for all covered species. The results of this inventory are important for habitat and land acquisition requirement tracking and long-term management and monitoring (see Chapter 7).

## **Acquisition of Occupied Habitat for Select Wildlife Species**

The Wildlife Agencies require additional assurances that land will be acquired for the Reserve System that will support occupied habitat for five covered wildlife species:

- Bay checkerspot butterfly,
- California red-legged frog,
- California tiger salamander,
- Western pond turtle, and
- Foothill yellow-legged frog.

These species were selected because they are known to consistently breed in multiple locations in the study area or because they are so rare that it is necessary to be assured that occupied lands are protected. It is critical that the Reserve System protect some of this occupied habitat to ensure the conservation of the species in the study area.

Occupancy requirements for the purposes of this Plan do not need to be met at the time of land acquisition. This flexibility provides the opportunity to acquire unoccupied habitat that is later occupied as a result of improved management, habitat restoration (e.g., streams), or habitat creation (e.g., ponds) (see Chapter 5, Section 5.2.3 *Reserve System* and Chapter 8, Section 8.2.5 *Wildlife Agencies*). The metapopulation dynamics of the Bay checkerspot butterfly warranted a specific temporal component of the occupancy requirements, which are described in detail below.

It is important to note that these occupancy requirements are designed to aid the Wildlife Agencies in making their regulatory findings. The Implementing Entity will provide habitat management, habitat enhancement, habitat restoration, and/or habitat creation, in addition to these basic occupancy requirements, because these requirements are not the minimum species targets for the Reserve System. To meet the biological goals and objectives for these species (and all covered species), the Plan includes additional restoration/creation, and monitoring beyond those noted in the following basic occupancy requirements. The abundance and condition of the covered species in the Reserve System will be monitored to determine the effectiveness of the conservation actions.

### Bay Checkerspot Butterfly

For the Bay checkerspot butterfly, occupancy will be demonstrated in both core and satellite habitat units (see **Table 5-7** and the species account in **Appendix D** for definitions of core and satellite habitat units). The occupancy requirement will be met by demonstrating the presence of larvae and adults (not just adults, in case individuals fly through a site but are not reproducing).

The Implementing Entity will acquire and manage enough habitat for Bay checkerspot butterfly to ensure occupancy of each of the four core habitat units identified in Figure 5-A of the 1998 Serpentine Recovery Plan (Kirby, Metcalf, San Felipe, and Silver Creek Hills). Occupancy in these four core habitat units must be demonstrated at least four out of every 10 consecutive years of the permit term. This occurrence frequency is based on population data reported for the Kirby, Metcalf, and Silver Creek core habitat units, which are fairly robust (e.g., Kirby population data dates back to 1991).

The Implementing Entity will also acquire and manage land to ensure occupancy of at least three of the six (50%) satellite habitat units identified in the 1998 Serpentine Recovery Plan (W. Hills of Santa Clara Valley, Tulare Hill, Santa Teresa Hills, Calero, Communication Hill<sup>17</sup>, or North of Llagas Avenue) (**Table 5-7**) by Year 45. Occupancy is less certain in satellite habitat units because of their smaller size than and greater distance from core habitat units. Because of their isolation, they are colonized only periodically by long-distance dispersal events. Because of their small size, populations that become established go extinct quickly due to small population sizes (Harrison et al. 1988). For these reasons, occupancy of a total of 50% of satellite habitat units must only be demonstrated once by Year 45. For example, occupancy of Tulare Hill in Year 5, North of Llagas Avenue in Year 10, and Calero in Year 15 would fulfill the satellite component of the occupancy criteria. The satellite units with the greatest chance of occupancy due to size, proximity to core units, and expected improvements in habitat management are:

- Santa Teresa Hills
- Tulare Hill
- Calero

There is a potential that less than 50% of the satellite populations will be occupied by Year 45. If this occurs, the Implementing Entity will remain in compliance with the satellite occupancy criteria if it demonstrates to the Wildlife Agencies that it has managed satellites incorporated in the Reserve System in accordance with the Plan and Bay checkerspot butterfly has not colonized these sites for reasons beyond its control (e.g., climate change).

<sup>17</sup> Communication Hill is considered a historic/unoccupied site. Therefore, the three occupied satellite units could occur in any of the five remaining satellite units that are described by this Plan as occupied, potential, or occupancy unknown.

### **California Red-legged Frog, California Tiger Salamander, and Western Pond Turtle**

California red-legged frog, California tiger salamander, and western pond turtle have been grouped for the purposes of the species occupancy requirement because of their co-reliance and frequent co-occurrence in ponds and perennial wetlands in the study area. To simplify this requirement, the species occupancy requirement for these three species is defined as a minimum percent occupancy of the number of freshwater wetlands and ponds in the Reserve System (not wetland or pond acreage).

- California red-legged frog = 40% of ponds and wetlands in each of the federal Recovery Units 4 and 6 in the Reserve System (which correspond to the two major watersheds in the study area).
- California tiger salamander = 30% of ponds and wetlands in the entire Reserve System.
- Western pond turtle = 25% of ponds and wetlands in the entire Reserve System.

The occupancy requirements for these species must be demonstrated when the Reserve System is fully acquired, which will be at or before Year 45. Occupancy is demonstrated the first time that a pond or wetland is occupied by the species, as defined above. Once occupied, a pond or wetland is counted as occupied for this requirement for the rest of the permit term, even if it becomes unoccupied later<sup>18</sup>. As is the case for all covered species habitat, habitat for these species contained within the Reserve System will be protected, enhanced, restored, and monitored. As such, once presence is documented, there is a high probability that these species will persist within the Reserve System.

To ensure that the Implementing Entity is making progress towards these requirements during the permit term, these occupancy requirements must also be met for the Reserve System at Year 30, minus 5% for each one (i.e., 35% for California red-legged frog, 25% for California tiger salamander, and 20% for western pond turtle). The measurement will be made based on the total Reserve System at Year 30.

For the frog and salamander, an entire wetland or pond is considered occupied if the species is reproducing successfully, which is defined as evidence of metamorphosis. This metric ensures that ponds have the correct hydroperiod to support the full life-cycle of California red-legged frog and California tiger salamanders. A site is considered occupied by western pond turtle if basking is observed by adults and juveniles at the same site. Observations of juveniles and adults provide evidence of successful reproduction, and therefore is an indication of population viability. The presence of multiple age-classes is important given that adult turtle populations can persist in highly modified environments

<sup>18</sup> If a pond or wetland becomes unoccupied later, the Implementing Entity will consider altering management at that site to encourage recolonization through the adaptive management process, but that outcome will not affect the occupancy requirement for that site. See Chapter 7 for more details on the monitoring and adaptive management program.

providing the illusion that the population is stable when in fact reproduction is unable to take place, likely due to degraded upland nesting habitat (**Appendix D**).

Ponds created or wetlands restored in the Reserve System that meet the occupancy criteria will count towards the occupancy requirement. Although unoccupied created ponds or restored wetlands would not contribute to the occupancy requirements of this Plan, they would be credited toward the aquatic land cover requirements described in **Table 5-12**. In other words, these created and restored sites do not count as part of the total ponds and wetlands assessed in the Reserve System for this requirement, if these sites are unoccupied. This approach creates an incentive to create ponds and restore wetlands that are occupied by one or more of the covered species.

The occupancy requirements were derived from three data sources, East Bay Regional Park District (Bobzien and DiDonato 2007), and the Central Valley of California (Germano and Bury 2001). Henry W. Coe State Park has the largest data set in the study area on ponds and wetlands and their occupancy by these three species. Surveys of 136 ponds and wetlands were conducted from 2001–2007 in the park (Belli 2007), most of which were in the study area (the remaining sites were just outside the study area in Santa Clara and Stanislaus Counties). The land cover types in Henry W. Coe State Park are similar to those in the rest of the study area. However, there is less grassland in the park than in the rest of the study area because of its higher elevation.

East Bay Regional Park District conducted surveys of 271 ponds 1996, 2000, and 2004. All ponds were surveyed at least once and many ponds were surveyed more than once (Bobzien and DiDonato 2007). Although not in the study area, the habitats, landscapes, and topography of the park lands within the East Bay Regional Park system are similar to that of the study area. The survey in the Central Valley of California was conducted in 1999 at 55 aquatic sites in the Sacramento and San Joaquin Valleys; 27 of these sites were ponds or lakes (Germano and Bury 2001). Only the data from ponds and lakes was considered for this analysis.

Surveys in Henry W. Coe State Park found California red-legged frog in 41 ponds (30.1%), California tiger salamander in 9 ponds (6.7%), and western pond turtle in 18 ponds (13.2%). The ponds and wetlands in Henry W. Coe State Park are representative of the ponds and wetlands expected to be found in the Reserve System, with two exceptions. First, Henry Coe is at higher elevations than the expected Reserve System. This means that California tiger salamander will likely be more common in the Reserve System than in Henry Coe, all else being equal. Second, there is no active predator removal program in Henry W. Coe State Park to remove bullfrogs, bass, and other nonnative predators. Therefore, California red-legged frog and California tiger salamander are expected to be more abundant in the Reserve System than in Henry W. Coe State Park due to the aggressive predator control planned for the Reserve System.

Surveys of ponds in the East Bay Regional Park District system found California red-legged frog in 75 of 271 ponds (27.7%) and California tiger salamander in 75

of 170 ponds within the range of that species (44.1%) (Bobzien and DiDonato 2007). Western pond turtle occurrences were not reported. The East Bay Regional Park District has an active predator-control program in ponds and other wetlands. Therefore, the abundance of the two amphibians within their ponds is likely more representative of what the Reserve System should expect, with one exception. California tiger salamander distribution within the East Bay Regional Park District may be higher than what will be seen in the Reserve System because the Reserve System will include ponds and wetlands in the Santa Cruz Mountains (not just the Diablo Range, where the East Bay Regional Park District is found). California tiger salamander is likely less abundant in the Santa Cruz Mountains than in the Diablo Range.

The aquatic surveys of the Central Valley ponds and lakes found western pond turtle at 10 of the 27 ponds and lakes surveyed (37%). Amphibians were not surveyed. In this study, sites were selected based on known historic or suspected occurrences of western pond turtle (Germano and Bury 2001). Therefore, the sample was likely biased towards occupied sites and may overestimate the occurrence of this species in all ponds and lakes in the Central Valley.

The species occupancy target for California red-legged frog (40%) was set for the study area as a rounded number greater than the results of these two applicable studies, considering the factors outlined above. The minimum occupancy targets for California tiger salamander and western pond turtle (30% and 25% respectively) were set at or above the midpoint between the two applicable study results. In all three cases, targets take into account the assumed success in attracting these species to created ponds. Nonnative barred tiger salamander alleles will be assumed present in wetlands and ponds containing paedomorphic tiger salamanders<sup>19</sup>; therefore, such ponds and wetlands will not count towards the California tiger salamander species occupancy requirement (see **Appendix K** for details).

Species occupancy for California red-legged frog must be met equally in both of the major watersheds in the study area, which match the two federal recovery units identified in Figure 5-B of the Species Recovery Plan (Units 4 and 6; U.S. Fish and Wildlife Service 2002). In other words, 40% of the ponds and/or wetlands in the Coyote Creek/Guadalupe River portion of the Reserve System will be occupied and 40% of the ponds and/or wetlands in the Pajaro River watershed portion of the Reserve System will be occupied.

Both California red-legged frog and western pond turtle also occur in streams throughout the study area. However, accounting for occupancy in streams, which do not have discrete boundaries as do ponds and wetlands, will complicate compliance monitoring. Furthermore, both species are known to travel significant distances from breeding sites, which would make it more difficult to identify the extent of “occupied” stream length. For these reasons, and because the majority of the conservation benefits afforded to these two species will be

<sup>19</sup> Paedomorphic tiger salamanders are sexually mature adult tiger salamander that retain juvenile characteristics (e.g., maintain larval form). Paedomorphosis is a characteristic of non-native barred tiger salamanders, whereas, California tiger salamanders always metamorphose prior to sexual maturity.

through the preservation and enhancement, restoration, and/or creation of ponds and wetlands (**Table 5-12**), occupancy requirements will be measured by pond and wetland habitat within the Reserve System, not streams.

The species occupancy target for western pond turtle is based on the best available data and the need to meet the regulatory standard to contribute to recovery. If future monitoring data or other information suggests that this target is biologically unattainable, the Implementing Entity will confer with the Wildlife Agencies to revise the target (including how it is measured) to better meet the regulatory standards and the biological goals and objectives of this Plan. Additional conservation actions (e.g., translocation) may be necessary to achieve conservation for this species. All translocation activities will be reviewed and approved by the Wildlife Agencies in advance of translocation activities occurring.

### **Foothill Yellow-legged Frog**

Foothill yellow-legged frog is known or suspected to occur in at least five major rivers and creeks in the study area based on occurrence records and the presence of suitable habitat:

- Upper Penitencia Creek, below Cherry Flat Reservoir
- San Felipe Creek
- Upper Coyote Creek and its tributaries, above Coyote Reservoir
- Llagas Creek above Chesbro Reservoir
- Upper tributaries to Uvas Creek, including Little Arthur and Bodfish Creeks

Additional populations may be present in the many unsurveyed streams of the study area. The population in Upper Coyote Creek is located in Henry W. Coe State Park and the Palassou Ridge Open Space Preserve. The populations in Upper Penitencia Creek and San Felipe Creek are partially contained in Alum Rock Park and the San Felipe Ranch Conservation Easement, respectively. Known populations occur in three of the major watersheds in the study area shown in **Figure 3-6** (Coyote, Llagas, and Uvas). Additional populations may occur in two more watersheds (Pacheco and Pescadero).

For the purposes of demonstrating occupancy of foothill yellow-legged frog in this Plan, occupied habitat within the Reserve System is defined as perennial streams with an observation of egg masses by Year 45. Although there are some reports of foothill yellow-legged frogs breeding in perennial tributaries in the study area, the species typically breeds in perennial portions of main-stem channels (E. Gonsolin pers. comm.; Kupferberg et al. 2009). This is likely because main stem channels provide habitat that is more conducive to successful breeding in the study area (i.e., areas of shallow, low velocity flows during the spring months) as opposed to perennial portions of tributaries that often have turbulent conditions (E. Gonsolin pers. comm.). The presence of egg masses will adequately demonstrate occupancy because spring breeding and summer tadpole rearing represent critical life stages for this species (Kupferberg et al. 2009).

Foothill yellow-legged frogs are known to travel significant distances and are highly stream dependent (**Appendix D**). For these reasons, correlating occupied stream segments (i.e., miles of stream) to observed egg masses will be difficult. Therefore, the foothill yellow-legged frog occupancy requirement for this Plan will be met when the Implementing Entity protects occupied habitat in the Reserve System in at least four of the watersheds in **Figure 3-6**. This target was set based on the probability of occupancy in the Reserve System in each of the watersheds in **Figure 3-6**: very high in the Reserve System within the Llagas watershed, high in the Coyote watershed, moderate-high in the Uvas watershed, and moderate in the Pacheco and Pescadero watersheds. These rough probabilities were based on the location of known occurrences, highly suitable habitat, and Reserve System acquisitions.

Occupied habitat in the Reserve System must be in both the Diablo Range and in the Santa Cruz Mountains. Historic populations of this species have likely been lost from the Santa Clara Valley floor (H.T. Harvey & Associates 1999), so it is important to protect occupied habitat in both mountain ranges in case there is no connectivity between the two ranges.

Furthermore, occupancy will be demonstrated upstream of dams that present permanent barriers to the species or on streams unaffected by dam operations. Although foothill yellow-legged frogs could occur downstream of dams within the study area, remnant populations are likely to be adversely affected by continued dam operations. Foothill yellow-legged frog populations in regulated rivers are likely at greater risk of extinction by virtue of their low abundance, even before the effects of hydrologic stressors are considered (Kupferberg et al. 2009). For these reasons, the best opportunities for maintaining and increasing foothill yellow-legged frog populations exists upstream of dams, or in streams unaffected by dam operations, and will be the focus of the conservation strategy for this species (e.g., see Goal 16 for this Plan).

## Stay-Ahead Provision and Rough Proportionality

The timing and sequence of reserve assembly relative to impacts of covered activities is critical to the success of the Habitat Plan. Progress toward assembling the Reserve System must *stay ahead* of progress toward total impacts allowed under the permit. This sequence ensures that reserve assembly is keeping pace with development and that the Implementing Entity is making steady progress toward the complete Reserve System.

Such progress toward assembly of the Reserve System is a requirement under the NCCP Act. The NCCP Act requires that implementation of mitigation and conservation actions be “roughly proportional in time and extent to the impact on habitat or covered species authorized under the plan” (California Fish and Game Code Section 2820[b][9]). To meet the requirements of this section, CDFG requires that NCCPs make progress towards the final conservation goals (i.e., the ultimate size and configuration of the Reserve System) in proportion to the impacts of covered activities. The Stay-Ahead provision applies to both preservation/enhancement and restoration commitments in this Plan and is

further described in Chapter 8 (Section 8.6.1 *Stay-Ahead Provision*) addresses this requirement.

If impacts occur more slowly than expected, strict adherence to the Stay-Ahead provision would result in relatively slow growth of the Reserve System initially, followed by a rapid expansion of the Reserve System in order to meet the final acquisition targets. To ensure that the Implementing Entity makes steady progress towards the final land acquisition targets, in Year 20 of implementation, the Implementing Entity will work with the Wildlife Agencies to conduct a formal and complete review of progress toward building the Reserve System. To ensure that the Implementing Entity makes steady progress towards final restoration/creation goals, interim deadlines are established in **Table 5-14** for each watershed in the study area. Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management* also includes deadlines for riverine acquisition and restoration. The Stay-Ahead provision described above must always be followed.

## Land Acquisition Outside the Permit Area

In order to meet the requirements of this conservation strategy, all land acquisition must occur within the Habitat Plan permit area, including the *Expanded Study Area for Burrowing Owl Conservation*<sup>20</sup> (**Figure 1-2**). Parcels extending beyond the County and/or Habitat Plan permit area could be counted toward land acquisition commitments of this Plan if more than half of the parcel is located within the permit area. For example, land acquisition along the ridgeline of the Santa Cruz Mountains may include some land in Santa Cruz County. If parcels are acquired that include land outside the permit area, land cover types on that parcel will be credited toward applicable Plan requirements as long as less than half the parcel is outside the permit area and the total land area credited outside the permit area is less than 250 acres.

As described in the land acquisition strategy, regional linkages are important to some covered and other native species (**Table 5-9** and **Figure 5-6**). The Implementing Entity is encouraged to partner with other organizations to secure these regional linkages inside and outside the study area. For example, the linkage from the Santa Cruz Mountains to the Gabilan Range will not function unless suitable habitat is present in four counties: Santa Clara, Santa Cruz, Monterey, and San Benito. Securing this linkage will require strong partnerships.

## Conservation in the Study Area beyond Habitat Plan Requirements

The land acquisition requirements above are not designed to provide the blueprint for all conservation in the study area. Open space acquisition will

<sup>20</sup> Land acquisition in the *Expanded Permit Area for Burrowing Owl Conservation* will only be done to satisfy requirements for the burrowing owl conservation strategy, not other species covered under this Plan.

continue separate from the Habitat Plan during and after the permit term, and projects not covered by the Plan will need to implement their own mitigation. However, conservation that occurs separate from this Plan will benefit the Plan and the biological resources of the study area if these acquisitions occur in coordination with the Plan. The following general priorities were developed to help guide conservation that occurs separate from the Habitat Plan. These priorities can also guide conservation actions under the Habitat Plan in the event that separate conservation or other actions prevent land from being acquired under the Habitat Plan in the areas listed above. These priorities build on the Habitat Plan Reserve System to create a larger system of conservation and open space in the study area.

- **Conservation Analysis Zones with High Acquisition Priority.** More land acquired in the conservation analysis zones already designated at a high priority for conservation will strengthen the Reserve System by creating larger, more contiguous conservation areas that are better able to preserve covered species habitat and landscape linkages.
- **Uvas-4, 5, Pescadero-1.** Additional land acquisition in these zones will increase protection in the Uvas and Pescadero watersheds to benefit native fish, California red-legged frog, California tiger salamander, and western pond turtle, among others. Land acquisition in this area could complete Landscape Linkage 13 between Mount Madonna County Park and the Reserve System in the southwestern corner of the study area.
- **Uvas-2 and 3.** Additional land acquisition in these zones will increase watershed protection in the Uvas watershed, protecting water quality and habitat for California red-legged frog, California tiger salamander, and western pond turtle along Uvas Creek, above and below Uvas Reservoir. Land acquisition will also support Landscape Linkage 13 and help to connect Mount Madonna County Park with open space surrounding Uvas Reservoir and the Reserve System to the north.
- **Coyote-9.** Land acquisition in this zone will increase protection of annual grassland and blue oak woodland near Alum Rock Park and the Reserve System in Coyote-7 and Alameda-1. Additional protection in this area will preserve more habitat for California red-legged frog, California tiger salamander, and western pond turtle and create a stronger linkage to outside the study area to the north (Landscape Linkage 4).
- **Coyote Ridge.** While most of Coyote Ridge is targeted for land acquisition (see Coyote-4, 5, and 6), parcels with no or lower-quality habitat for Bay checkerspot butterfly and serpentine covered plants would not be included in the Reserve System. Additional land acquisition in Coyote Ridge, particularly in the northwest, would provide additional covered species habitat and important buffers between the Reserve System and existing urban development.
- **Pacheco Watershed.** Additional land acquisition in the Pacheco watershed would strengthen and expand the Reserve System and could provide better linkages to Henry W. Coe State Park and Pacheco State Park. Although development threats in this watershed are low, increased open space could

provide much greater opportunities for habitat enhancement and long-term monitoring.

- **Uvas-1.** Additional land acquisition in the upper Uvas Creek watershed could expand the existing open space and the Reserve System that protects some of the only stands of knobcone pine woodland in the study area. Additional land acquisition could protect the remaining stands of this land cover type and enhance watershed and water quality protection.

## 5.3.2 Landscape Conservation and Management

This section discusses conservation and management in the permit area at the landscape level. The following sections describe conservation and management guidelines and principles for each natural community. Conservation and management guidelines specific to individual covered species are presented in the discussion of the relevant natural community. Additional conservation and management discussions are also included in the species-specific sections (see Section 5.4 *Benefits of and Additional Conservation Actions for Covered Species*).

Each section is organized as shown below.

- **Biological Goals and Objectives:** A summary of the biological goals and objectives for that community presented in **Table 5-1b**.
- **Acquisition, Restoration, and Enhancement:** A summary of the acquisition, restoration, and enhancement requirements as they apply to that landscape or natural community, referencing the biologically appropriate conservation action from **Table 5-2a or 5-2b**.
- **Management Techniques and Tools:** Guidelines and specific techniques and tools that are recommended to achieve the biological goals and objectives. This section provides details on the conservation actions in **Table 5-2b**.
- **Threats and Uncertainties:** Describes the uncertainties associated with the conservation actions and external threats that may make their successful application more difficult.

## Biological Goals and Objectives

A primary goal of this Plan is to protect and maintain natural and semi-natural landscapes within the study area that are large enough to accommodate natural processes beneficial to populations of covered and other native species. The Plan will accomplish this by establishing a Reserve System within the permit area that will preserve a minimum of 33,205 acres (**Table 5-13**). Up to an additional 13,291 acres of existing open space will be incorporated into the Reserve System to enhance their long-term management. The total size of the Reserve System will therefore be a minimum of 46,496 acres.

This Reserve System will support a range of environmental gradients (such as slope, elevation, aspect, rainfall) and a representative diversity of natural communities. In addition to protecting riverine systems and hydrologic function through fee title and conservation easement, the Plan will benefit stream and riparian habitats through the stream setback (described in Chapter 6, Section 6.5, subheading *Condition 11 Stream and Riparian Setbacks*) and by implementing stream and riparian restoration projects.

The Reserve System will be assembled to reduce habitat fragmentation and to sustain and enhance the effective movement and genetic exchange of native organisms within and between natural communities. Habitat connectivity and important movement and dispersal routes will be protected and, when necessary, enhanced inside the study area. Further, the Implementing Entity will increase the permeability for species movement in targeted areas.

The Plan will also enhance or restore representative natural and semi-natural landscapes to maintain or increase the diversity and distribution of native species. Enhancement and restoration activities within the Reserve System will increase the total area of high-quality habitat for covered and other native species and promote those natural processes that define each natural community (e.g., succession, competition). The Reserve System will be large enough to accommodate management for conflicting life history requirements between species. The Reserve System will also be large enough to allow natural disturbance regimes such as fire and flooding to occur. When these natural disturbances cannot be allowed, other management actions will be implemented that mimic those disturbances and yield similar results. Finally, the Plan will eradicate, where possible, or at least reduce the cover, biomass, and distribution of target nonnative invasive plants and reduce the number and distribution of nonnative invasive animals within the Reserve System.

## Acquisition, Restoration, Enhancement, Creation

### Acquisition

During the course of Plan implementation, a minimum of 33,205 acres of natural land cover types will be acquired through fee title or conservation easement to create the Reserve System (**Table 5-13**).

This Plan does not require protection of agriculture land cover types, although the Implementing Entity may acquire and manage agricultural lands if it determines such acquisition would support the goals and objectives of the Plan. All else being equal, the Implementing Entity will acquire parcels with natural land cover types over cultivate agriculture to fulfill the goals and objectives of this Plan.

## Enhancement and Restoration of Natural Communities

All land and aquatic habitats in the Reserve System, including streams, will be enhanced to benefit covered and other native species as indicated by pre-acquisition assessments and targeted studies and informed by the monitoring and adaptive management program (LM-6, LM-7a, LM-7b). Existing open space included in the Reserve System would add up to 13,291 acres of natural land cover that would also be enhanced (**Table 5-5**). In total, the Reserve System would encompass 46,496 acres to 46,920 acres.

A required compensation ratio for specific land cover types, plus a minimum compensation requirement regardless of the level of impact, will result in restoration or creation of an estimated 339 acres of riparian forest and scrub, 75 acres of wetland, 72 acres of pond and 10.4 miles of streams in the Reserve System if all anticipated impacts occur (LM-6, LM-7a, LM-7b; see sections below on each land cover type for further information) (**Table 5-13**). The minimum compensation requirement will allow the Plan to contribute to the recovery of these resources within the study area during the permit term.

Restoration and enhancement of natural communities involves the recovery of ecosystem function that has been lost or degraded, respectively. Implementation of restoration or enhancement activities will initiate or accelerate ecosystem recovery with respect to functional processes, species composition, and community structure. Typically, the aim of restoration and enhancement is to return an ecosystem to a historic state or within the bound of its historic trajectory. In other words, the goal would be to recreate an ecological state that existed prior to the degradation of the system (Clewett et al. 2005). However, the level of restoration and the final result of these activities will be constrained by current conditions and feasibility. For the purposes of this Plan, restoration and enhancement activities will be guided by the biological goals and objectives of the Plan, with the overarching goal of enhancing ecological values in protected landscapes.

There are generally four broad steps to determine a restoration or enhancement program (Hobbs and Norton 1996).

- Identify the processes that have led to or are leading to degradation.
- Develop methods to slow or reverse the decline.
- Determine realistic goals and clear measures of success.
- Develop techniques for implementing these goals.

In this Plan, the techniques for enhancement and restoration are articulated as conservation actions and are summarized in each natural community section below. Guidelines are also presented in each section, where applicable, for selecting restoration sites. However, the following broad recommendations apply to all restoration activities.

- **Manage at multiple levels.** Biological processes occur at a wide variety of scales across the landscape. Restoration and enhancement activities will

therefore be planned and executed with these multiple levels in mind. For example, the enhancement of covered plant occurrences will likely occur at a relatively small species level due to the small size of many occurrences. Microhabitats for covered plants such as soil texture, soil depth, rockiness, and nearest neighbor plants will be considered. However, other processes operating at larger levels—such as the spread of invasive species, hillside erosion or deposition, and the patterns of wildfires—will also affect plant habitat enhancement. To be successful, management actions will consider and anticipate processes operating at multiple levels.

- **Balance conflicting species needs.** The effects of an enhancement or restoration action must be evaluated for all covered species before management decisions are finalized. For instance, grazing generally benefits Bay checkerspot butterfly and many of the covered plant species. In contrast, Mt. Hamilton thistle may require grazing exclusions to prevent livestock from trampling its habitat. Similarly, some pond-dependent covered species can require conflicting habitat conditions. Dense emergent vegetation around pond margins can provide good habitat for tricolored blackbird and California red-legged frog but may not provide adequate habitat for California tiger salamander or western pond turtle. The large size of the Reserve System will allow disparate actions to occur in different places and benefit all of the covered species.
- **Account for inherent variability.** It is important to acknowledge that chance events can often exert strong effects on species and natural systems. The most common of these chance events are weather-related factors such as rainfall, temperature, timing of seasons, drought, and the unknown ramifications of global climate change. Other chance events are associated with species populations themselves; these may include reproductive success and dispersal. Such inherently uncontrollable variables and their effects on covered species are best offset by maintaining within the Reserve System a variety of microsites, environmental gradients, and management treatments. This ensures that covered species can take advantage of suitable habitat during good seasons and find refugia in bad seasons.
- **Mimic natural processes.** This is a management technique that recognizes that natural processes (e.g., hydrologic regimes, wildfire) are the fundamental forces that shape natural systems and create and maintain habitat for covered species. Therefore, management actions will focus on defining, maintaining or restoring and, as indicated by pre-acquisition assessments and targeted studies and informed by the monitoring and adaptive management program, enhancing these natural processes. If not feasible, then the effects of those processes can be duplicated by alternative management actions.
- **Use adaptive management principles.** Flexibility and adaptation will be embraced in making management decisions and improving restoration and enhancement activities within natural communities. Adaptive management principles (described in Chapter 7) will apply across the range of general principles as well as to the specific management techniques and tools described below.

## Management Techniques and Tools

Most management techniques and tools are discussed under each natural community. Some techniques, however, apply to several natural communities or to the Reserve System as a whole. These landscape-level management actions are described below.

### Connectivity and Permeability

One important measure of the Reserve System's success will be the degree to which it allows native wildlife species to move freely within and between the reserve units and to other habitat outside the Reserve System. In addition to wildlife, it is also important that plant occurrences be able to disperse with minimal limitations in order to facilitate occurrence expansion and ensure long-time viability within the context of global climate change. To achieve this, the permeability and connectivity of the study area will be increased by the actions listed below. In landscape ecology, connectivity refers to corridors between core habitat patches that allow for species movement. Protecting species habitat between two existing large protected areas of species habitat to link the two areas is an example of increasing landscape connectivity. Permeability, on the other hand, refers to the relative potential for a species to move across a landscape (Singleton et al. 2002). For example, removal of a fence or other barriers to species movement would increase landscape permeability. While these measures are targeted toward wildlife movement, it is assumed that they will also enhance opportunities for plant dispersal and occurrence expansion.

- Retrofitting or removing fences that serve as barriers or hazards to wildlife movement.
- Improving culverts and other crossing points under roads to make them more attractive and safer for wildlife.
- Perforating or modifying median barriers within the constraints of public safety to make road crossings more available in locations safe for wildlife.
- Collecting consistent data on wildlife movement throughout the study area to better inform the location and type of structures to facilitate movement.

Most fences in the Reserve System will remain and will be utilized for grazing management. Those that are unnecessary will be removed to increase the continuity of the Reserve System (LM-1). Additional fences may be installed to increase flexibility in grazing management or to exclude feral pigs from sensitive natural communities. Most existing private roads within the Reserve System will be utilized for management or monitoring purposes, but those that are unnecessary will be removed and decommissioned (i.e., returned to a natural condition) or stabilized and abandoned both to reduce hazards to wildlife and to reduce the erosion potential associated with dirt and gravel roads. Additional roads may be added to access parts of the Reserve System for management or monitoring purposes. These access routes will conform to the natural contours of

the surrounding landscape and will only be maintained to the extent necessary for access and to reduce the spread of nonnative plant species.

In general, roadways can be made safer for wildlife and for motorists by increasing the number and quality of opportunities for animals to cross them. Median barriers pose a serious hazard to wildlife; when animals try to cross such roads, they often become trapped at the barrier. Median barriers on several major roadways in the study area (e.g., SR 152, Monterey Road) prevent wildlife from crossing except at limited undercrossings. Strategically perforating these medians will both increase the safety of the roadways and increase the connectivity of the study area (LM-5) (see Chapter 6, Condition 6 *Design and Construction Requirements for Covered Transportation Projects*).

Culverts that create a one-way barrier<sup>21</sup> along waterways will be removed or retrofitted to allow movement of fish and aquatic amphibians both upstream and downstream (LM-2). In most cases, retrofitting involves replacing small obstructive culverts with larger, straight culverts to allow species to move through more readily. In some instances culverts may be replaced with clear-span bridges to increase the habitat quality of the waterway where it flows under the roadway (LM-3). This approach enhances the habitat (both aquatic and terrestrial) under the roadway for animal movement. In addition, existing culverts or bridges may be enhanced to increase wildlife movement through or under these permanent barriers. Fencing could be installed along the roadway to guide wildlife species away from the roadway and through undercrossings (LM-4) (see Chapter 6, Section 6.4.4, subheading *Condition 6 Design and Construction Requirements for Covered Transportation Projects*).

### Areas of Focus

Three primary areas of focus are suggested to improve landscape linkages in the study area using the techniques described above: Tulare Hill to Anderson Reservoir, Pacheco Creek (SR 152), and Pajaro River.

#### Tulare Hill to Anderson Reservoir

The section of valley floor between Tulare Hill and Anderson Reservoir is one of the narrowest points in the Santa Clara Valley. For wildlife moving between the Santa Cruz foothills and the Diablo foothills, this topographic pinch point is the closest connection, limiting the distance traveled across the valley floor (Linkages 6, 8, and 10 in **Table 5-9** and **Figure 5-8**) (see *Coyote-7 and -8* in Section 5.3.1 *Land Acquisition and Restoration Actions*).

U.S. 101 is a major barrier influencing wildlife movement across the valley between Tulare Hill and Anderson Reservoir. At least 24 undercrossings or culverts have been documented by CDFG along this stretch of U.S. 101 (**Figure 5-9a**). Most of the culverts would allow safe passage to many species of wildlife, although some are navigable only by the most agile species (e.g., bobcats). Many species of wildlife (e.g., bobcats, skunks, raccoons) have been

<sup>21</sup> One-way barriers occur when species can move in one direction, but not the other; for example, fish moving downstream but not upstream.

documented using these culverts, and most of the culverts are utilized by multiple species (T. Diamond pers. comm.).

All the culverts that adjoin open space Types 1, 2, and 3 on the west side of the highway provide a connection to the Coyote Creek Parkway. These culverts could be improved to better facilitate wildlife movement into and through the culverts. In addition, measures could be implemented to improve wildlife access to the few bridge underpasses along Coyote Creek. Increasing wildlife access to Coyote Creek will help to maintain this important landscape linkage between the Diablo Range and the Santa Cruz Mountains.

### **Pacheco Creek (SR 152)**

Retaining a habitat linkage within the Diablo Range will benefit several covered and other native species (e.g., San Joaquin kit fox, Tule elk, mountain lion) within the study area. Along the 6 miles of SR 152 there are only three breaks in the highway median barrier, each about 50 feet wide (**Figure 5-9b**). These three breaks provide some opportunities for wildlife to cross the highway, but given the high volume of traffic, the likelihood of wildlife successfully using these breaks is low. Increasing the number and quality of crossing opportunities along this stretch will create connections for wildlife across SR 152.

Conservation options that would increase the permeability of SR 152 are limited. There is the possibility of increasing the function of existing linkages by enhancing the few undercrossings on both sides of the highway (bridges and culverts) to make them more biologically appropriate for wildlife use (see *Pacheco 1–6* in Section 5.3.1 *Land Acquisition and Restoration Actions*).

In order to maximize connectivity in this area, enhancements will be prioritized by focusing on the features shown below in descending order.

- Bridges with naturally vegetated riparian corridors on both sides of the highway.
- Bridges with degraded or otherwise limited riparian corridors on one or both sides of the highway.
- Culverts or other small passageways.

### **Pajaro River**

In addition to providing local and regional habitat linkages to native species such as bobcat, and mountain lion, the Pajaro River riparian corridor supports many covered species within the study area. It also provides connectivity to areas outside the study area—specifically the Gabilan Range and Monterey Bay (Pacific Ocean). The river itself provides movement habitat for native fish and linkages to breeding and rearing habitat in the upper reaches of its tributaries (Linkages 11, 12, and 17 in **Table 5-9 and Figure 5-6**). The riparian corridor associated with the river supports California red-legged frog and likely supports least Bell's vireo, though this species has not been documented along the Pajaro in recent years.

### Monitoring Wildlife Movement

The Implementing Entity will institute a data collection program to better understand how wildlife moves within and through the study area. While the areas listed above will likely be the focus of monitoring efforts, at least initially, this program will help determine linkage and connectivity throughout the study area. It will also help to define the role of the study area in the overall connectivity of the region. The data collected through this effort will be available for design and implementation of covered road projects. This program will remove the burden of data collection from each participating agency and ensure that all the data collected during the permit term is collected and collated consistently, is maintained in a central location, and is accessible. The program is described in Chapter 7, Section 7.3 *Monitoring and Management Actions*.

### Feasibility Study

A feasibility study will be initiated by the Implementing Entity when adequate monitoring data exist on wildlife movement in the three focal areas described above or by year 10 of implementation, whichever comes first (STUDIES-1). The Implementing Entity will commit \$500,000 to fund this study, which will evaluate the following questions for each of the three focal areas.

- Based on existing monitoring data, what feasible engineering options are available, small and large, to improve connectivity for the covered species and for native wildlife in general?
- What is the relative feasibility of these options based on factors such as regulatory permitting, cost, environmental impacts, and land use and safety compatibility?

### Fire Management

In addition to protection by city fire departments, the study area is served by the Santa Clara County Fire Department and Cal Fire. Cal Fire is often the primary responder to wildfires in natural areas<sup>22</sup> (California Department of Forestry and Fire Protection 2005) and will likely be the primary firefighting agency within Reserve System.

Local wildfire responses may not always benefit covered natural communities and species in the Reserve System. Aggressive response to wildfires can damage topsoil or cause excessive erosion, particularly if heavy machinery or chemical treatments are used to create firebreaks or suppress flames. Most of the natural communities in the study area are adapted to fire and respond positively after a burn. Some communities (e.g., chaparral, foothill pine-oak woodland) and species (e.g., Coyote ceanothus) require fire for regeneration and may require some level of burning to continue to persist. However, fire also often threatens human lives and property. These differing perspectives on fire need to be balanced during Plan implementation.

<sup>22</sup> Three battalions in the Santa Clara Unit of Cal Fire serve the study area: Battalion 1 (Morgan Hill), Battalion 2 (San José), and Battalion 7 (South Santa Clara County) (California Department of Forestry and Fire Protection 2005).

Fire management will be a component of each reserve unit management plan developed as the reserve units are acquired and incorporated into the Reserve System. The fire management component will include discussions with Cal Fire and other local fire-fighting agencies on the use of biologically appropriate management response measures for fire events and fire-dependent ecosystems (LM-8). This general fire management component for the Reserve System should be based, in part and as applicable, on agreement between USFWS, CDFG, and the U.S. Forest Service on fire-fighting techniques. Fire management will be incorporated into the reserve unit management plans prepared for each reserve unit within 5 years of the first acquisition of the land for the reserve unit. The reserve unit management plans will include a range of fire response, from full suppression when wildfires compromise public safety and personal property, to less than full suppression in predetermined areas of the reserve unit where public safety and personal property is not compromised, and fire-dependent natural communities are present. The plans may include controlled burn and let-burn components. The goal of such components would be to reduce fuel loads and decrease fire intensity while promoting fire-dependent natural community regeneration and a natural successional process where feasible. This approach would protect public safety, personal property, and sensitive natural communities while allowing for persistence of natural processes in fire-dependent natural communities. The reserve unit management plan will also include coordination with other land management agencies regarding allocation of prescribed burn permits from the Bay Area Air Quality Management District (BAAQMD).

The reserve unit management plans will describe minimum impact suppression tactics (also known as MIST<sup>23</sup>). Many plans utilizing these techniques and plans with low-impact rehabilitation (restoration) techniques have been developed in recent years. The goal of minimum impact suppression tactics is to safely suppress wildfire using environmentally sensitive suppression methods. Examples of minimum impact suppression tactics guidelines and actions that will be implemented include the following.

- Give preference to using methods and equipment that have the least adverse environmental effects.
- Give serious consideration to the use of water as a firelining tactic.
- Establish mobilization and demobilization areas to minimize spread of noxious weeds or diseases.
- Consider use of helibucket with water or foam before calling for airtankers and retardant.

In order to assure that the reserve unit management plans are followed during fires, the Implementing Entity will develop a wildfire local operating agreement for the Reserve System with Cal Fire and with any other firefighting agency that has responsibility for Reserve System lands. The operating agreement will ensure that the fire management components are implemented, that minimum

<sup>23</sup> For example, see <[http://www.wildfirelessons.net/documents/GB\\_MIST\\_Guidelines.pdf](http://www.wildfirelessons.net/documents/GB_MIST_Guidelines.pdf)> or the National Wildfire Coordinating Group at [www.nwcg.gov](http://www.nwcg.gov).

impact suppression tactics are utilized, and that post-fire restoration is carried out. An example of a local operating agreement that has been developed and utilized successfully is the Henry W. Coe State Park agreement with Cal Fire (California State Parks 2007). The wildfire local operating agreement will be in place within four years of permit issuance. This will allow time for the fire management component of reserve unit management plans to be developed and for the Implementing Entity to work closely with Cal Fire to develop the operating agreement.

Specifically, the wildfire local operating agreement for the Reserve System will, at a minimum:

- inform the firefighting agencies of Reserve System fire policies and sensitive resources<sup>24</sup>,
- inform the Implementing Entity of functions within the Incident Command System (Cal Fire) with respect to wildland fire,
- be the local working agreement between the Implementing Entity and firefighting agencies for all activities related to wildland fires in the Reserve System,
- designate responsibilities and guidelines for all activities related to wildland fires,
- allow the Implementing Entity to be a Resource Advisor in the Incident Command System in the event of a wildfire,
- identify minimum impact suppression tactics during and after wildland fires to ensure the minimum possible environmental impacts, and
- identify biologically appropriate and complete post-fire restoration and rehabilitation responsibilities.

Following a fire, the Implementing Entity shall initiate remedial measures as described in Chapter 10, Section 10.2.1 *Changed and Unforeseen Circumstances* subheading *Fire*.

To ensure the success of prescribed burns and minimum impact fire suppression techniques described in this Plan, the Implementing Entity will hire staff with expertise in controlled burns and fire fighting using these techniques. Staff with this expertise will also help to ensure clear and frequent communication with Cal Fire, which is essential to proper implementation of these techniques during a wildfire (D. Rocha pers. comm.). Staff with this expertise will also help to ensure immediate assessment and possible responses following detection of wildfires in the Reserve System.

---

<sup>24</sup> The Implementing Entity will update the appropriate local firefighting agencies of sensitive resources in the Reserve System as the Reserve System grows.

## Control Invasive Plants

Exotic plants (i.e., nonnative plants) pose a serious threat to ecosystem function, native biological diversity, and many covered plant species. However, many exotic plants cannot be effectively controlled due to their great abundance, high reproduction rate, and proficient dispersal ability; the high cost of control measures; or unacceptable environmental impacts of control measures. Therefore, the focus of control efforts in the Reserve System will be on the most invasive nonnative plants.

The spread of invasive plants may be exacerbated by covered activities. For example, increased human and pet populations can serve as dispersal vectors at the urban-wildland interface or through increased recreation in the Reserve System. Covered roads or other linear facilities can serve as dispersal corridors for these species. Accordingly, an aggressive control program is needed to minimize the adverse impacts of invasive plants and to enhance natural communities. Moreover, improved management within the reserves is expected to increase the resilience of natural communities to invasion by new invasive plants.

The Implementing Entity will address the control of invasive plants as a component of each reserve unit management plan. The appropriate management technique will be selected based on the invasive species present (**Table 5-20**). Control of invasive plants on reserve lands should begin immediately after acquisition if infestations are serious (e.g., yellow star-thistle), even if the reserve unit management plan is not finalized. Efforts to control invasive plants will be evaluated and revised as needed. Formal evaluations and revisions will take place at least every 5 years<sup>25</sup>.

The goals of the each reserve unit management plan will be to control the spread of noxious weeds (as defined by the California Department of Food and Agriculture) and invasive exotic plants listed by the California Invasive Plant Council (California Invasive Plant Council 2007 or latest list) into new areas and to control infestations of noxious and serious weeds. Another important goal will be to distinguish those species for which eradication or control will be the objective and those species that will be addressed through landscape-level management. The major elements listed below will be included in each reserve unit management plan.

- An assessment of the exotic plants likely to be invasive within the reserve unit that includes the following components.
  - Maps and descriptions of their distribution and abundance.
  - Their known or potential effects on ecosystem function, native biological diversity, sensitive natural communities, and covered species.
  - The means and risk of their spread to other areas within and outside the reserves.

<sup>25</sup> This is the approximate interval at which the list of invasive plants in California is updated by the California Invasive Plant Council.

- ❑ The cost, feasibility, and effectiveness of available control measures for each species.
- An assessment of invasive plants not currently found in the reserves but that are found nearby or in similar habitats and that might invade the reserves in the future. The assessment will include a description of known or potential effects on ecosystem function, native biological diversity, sensitive natural communities, and covered species.
- Development and application of criteria for establishing invasive plant control priorities.
- Integration and coordination of exotic plant control efforts in the Reserve System with efforts of other ongoing invasive plant control efforts such as those listed below.
  - ❑ Efforts to reduce the spread of barbed goat grass on Coyote Ridge (conducted by Dr. Stuart Weiss)
  - ❑ Efforts by SCVWD and County Parks to eradicate giant reed from Coyote Creek below Anderson Dam (County of Santa Clara Parks and Recreation Department 2007).
  - ❑ The integrated pest management program for yellow star-thistle in Santa Clara County that has been experimenting with biological control agents (coordinated by the County of Santa Clara Agriculture Commissioner).
  - ❑ Plans by County Parks to control invasive plants in various sites to be added to the Reserve System (conducted by County Parks and various consultants).
- A description of methods to control and prevent the establishment of invasive plants and criteria for evaluating the suitability of application of these methods based on site-specific conditions.
- A description of a process by which future invasive plants can be evaluated quickly to determine the best course of action for their effective removal or control.

Development of the invasive plant component of the reserve unit management plans will be coordinated with the Santa Clara County Division of Agriculture, the Santa Clara County Weed Management Area, and other major resource management agencies in the study area including SCVWD, the Open Space Authority, State Parks, and County Parks. Neighboring land management agencies such as Midpeninsula Regional Open Space District and Peninsula Open Space Trust will also be consulted. Because control of many invasive plants in the study area is a regional issue, coordination with these agencies is essential. Coordination could include sharing costs, staff, and equipment and conducting joint management programs to address the regional problem of invasive plants. Management to control invasive plants will be prioritized such that the invasive plants with the greatest impacts on covered species are addressed first.

## Herbicide Application

The selective use of herbicides is a conservation action proposed to control or eradicate invasive plants that may be used judiciously and occasionally within the Reserve System in specific locations (LM-14). Herbicide application may be necessary in particularly heavy infestations of exotic plants (e.g., Transline herbicide is effective in controlling yellow star-thistle). Certified personnel will conduct any herbicide application. Herbicides will be used with great caution, especially near seeps, creeks, wetlands, and other water resources. Herbicide use will be reserved for instances where no other eradication techniques are found to be effective. SCVWD is currently using this technique, among others, in the implementation of the Stream Maintenance Program within riparian zones (Santa Clara Valley Water District 2010). Herbicide restrictions within the Pajaro River watershed would also be applied, consistent with the guidelines of the Stream Maintenance Program (Santa Clara Valley Water District 2010).

## Control Nonnative Animals

### Bullfrogs and Nonnative Predatory Fish

The Implementing Entity will work to eradicate or reduce nonnative predators (e.g., bullfrogs, nonnative predatory fish) through habitat manipulation (e.g., periodic draining of ponds), trapping, hand capturing, electroshocking, or other control methods. Removal of bullfrogs and nonnative predatory fish will be a high priority in existing ponds or wetlands within the Reserve System (LM-13). The creation of new ponds or restoration of wetlands will only be conducted in areas where there are no known bullfrogs or where bullfrog control programs are underway or can be established.

Newly created ponds will be designed to periodically dry up naturally. In addition, where feasible, all new ponds will have drains installed to allow for occasional draining of the pond to control bullfrogs and nonnative predatory fish in case natural drying does not occur (POND-5). Some existing ponds might be retrofitted with drains if the nonnative species populations cannot be controlled by other means. Existing ponds without drains and that do not drain naturally may need to be drained periodically using pumps. During any maintenance or heightening of stock pond dams to increase capacity, the Implementing Entity-maintained rebuilt structures will be fitted with drains.

Draining ponds, sterilizing or removing subsoil, and removing bullfrogs can be effective at reducing predation by bullfrogs and other invasive species on covered amphibians and reptiles (Doubledee et al. 2003). Drainage of stock ponds and other wetlands will be carried out during the summer or fall dry season. Population models predict that draining ponds every 2 years will increase the likelihood that California red-legged frogs will persist in ponds with bullfrogs (Doubledee et al. 2003). SCVWD will evaluate water inputs from outside the study area to control nonnative fish and other exotic species from entering and establishing populations in waters inside the study area.

The SCVWD routinely distributes local and imported water supplies. Water distribution and release to stream channels may introduce and spread exotic, predatory, competitive, and habitat-altering species. To contain exotic species within off-channel recharge basins, current and future outflow systems will be screened.

### **Feral Pigs**

Feral pig impacts on natural communities are well documented within the study area. In Henry W. Coe State Park, adverse affects were documented on grassland, oak woodland, and aquatic natural communities (Sweitzer and Loggins 2001). Rooting disturbance by feral pigs allows nonnative invasive plants to establish in grassland and aquatic communities, and fall acorn foraging likely has a detrimental effect on oak regeneration (Sweitzer and Van Vuren 2002). An aggressive feral pig control program will be implemented on the Reserve System using trapping, hunting, or other effective control methods (LM-12).

The impact of rooting activities in pond and wetland natural communities may be reduced by fencing, although fencing to exclude feral pigs will need to be built for that purpose and maintained frequently in order to be effective. If fencing is used, it must be constructed so as not to restrict wildlife movement routes or corridors. In cases where livestock access to ponds and surrounding uplands is desired but feral pigs are degrading habitat, a feral pig control program could be initiated to improve pond habitats (POND-6). Feral pig control has been effective on San Francisco Public Utility Commission land in the adjacent Alameda Creek watershed (T. Koopman pers. comm.) and in Henry W. Coe State Park within the study area (Sweitzer and Loggins 2001; program is on-going). Feral pig control will be focused on parts of the permit area where the concentrations of feral pigs are high and impacts on native communities have been observed. It would be difficult to census the exact number of feral pigs within the Reserve System without an extensive effort. However, rooting disturbance can be monitored. Pig populations will be controlled during the permit term as long as their disturbance (i.e., rooting disturbance) adversely affects the Implementing Entity's ability to successfully implement the conservation strategy for this Plan.

### **Public Education and Outreach**

Public education and outreach will be an integral component of reserve management. The Implementing Entity will conduct outreach to local private and public landowners and residents that will include education on the Plan's management goals and objectives as well as implementation techniques. The focus of public education and outreach activities will be to raise landowner and public awareness of reserve management goals, actions and methods, and how the public can support and help implement them. For example, through the public outreach program, the Implementing Entity will obtain input from interested citizens on the preparation and implementation of reserve unit management plans. Activities may include education about

- not planting invasive plant species or releasing invasive animals such as bullfrogs,
- land uses to allow wildlife passage through streams and upland areas, or
- best management practices in agricultural and urban areas to minimize impacts to streams and other sensitive habitats.

The public education and outreach staff of the Implementing Entity will serve as a conduit for technical information and expertise available to landowners and the public. The Implementing Entity will develop and publish guidelines for local landowners and provide education programs to assist in the implementation of such guidelines. Public education and outreach will be coordinated with other local agencies providing similar services in the study area (e.g., County Parks, SCVWD, Open Space Authority).

To support the stream conservation actions (e.g., STREAM-1, STREAM-2, STREAM-3) and the stream and riparian setback condition (Chapter 6, Section 6.5, subheading *Condition 11 Stream and Riparian Setbacks*), the Implementing Entity will develop Stream Management (Riparian Land Use). Guidelines for private landowners, including an educational program to assist in the implementation of the guidelines, within five years of permit issuance. The guidelines and educational program will be based on SCVWD's *Guidelines & Standards for Land Use Near Streams* (Santa Clara Valley Water Resources Protection Collaborative 2006) developed for local permitting agencies, homeowners, and developers. The focus of the program and guidelines will be to raise landowner awareness of riparian conservation actions and methods that can be employed to protect riparian habitats and streams.

## Threats and Uncertainties

Threats to covered species and natural communities at the landscape level include those threats that this Habitat Plan seeks to minimize and offset, such as habitat loss, habitat fragmentation, and other forms of habitat degradation (see Chapter 4). The expected increase in vehicle traffic in the study area during the permit term will increase the threat to species that move across roads. Increases in population and transportation corridors will also increase the risk of the spread of invasive plants subject to the invasive plant component of the reserve unit management plan. Consequently, more invasive plants and exotic wildlife are expected to warrant eradication or control in the future.

While it is important to provide habitat linkages for native fish, wildlife, and plants, it is also important that those linkages do not facilitate an increase in nonnative species within the study area. The implication of management actions on the distribution of nonnative species will be weighed before these actions are implemented. In some cases, increasing habitat connectivity within the study area may introduce nonnative predators to areas that had been insulated from such introduction. For example, installing or improving culverts may increase access by covered amphibians to sites that expose them to new hazards. By creating the Reserve System and applying substantial long-term management and

monitoring through the Plan, some of these threats will be reduced and offset. However, many of these threats will remain outside the Reserve System.

Fire in the Reserve System is both an opportunity and a threat. Wildfires at moderate frequencies can maintain a healthy mosaic of natural communities without the buildup of too much fuel. If fires occur too infrequently, there is the threat that fires will burn too hot, damaging native ecosystems while promoting nonnative vegetation establishment. Fires that are too frequent could have similar effects. A combination of a let-burn policy, prescribed burns where and as needed, and restrictions on human access or uses in areas of the Reserve System with high fire risk should address this threat.

Climate change is one of the largest threats and uncertainties that the Plan confronts in the management of natural landscapes. Creating climate predictions for an area as small as the study area is not possible with current modeling technology and unlikely for an extended time. At the micro-scale, change in temperature, along with precipitation patterns (either wetter or dryer) could adversely affect covered species and natural communities in the Plan area. Accordingly, several ecological responses are possible during the permit term.

- **Phenological changes resulting in phenological mismatches.** Timing of seasonal events, such as migration, flowering, and egg laying, may shift earlier or later (Walther et al. 2002; Forister and Shapiro 2003; Root et al. 2003; Root et al. 2005). Such shifts may affect the timing and synchrony of events that must occur together, such as butterfly emergence and nectar availability.
- **Reduction in species and natural community range and distribution.** Narrowly distributed species and natural communities that already have restricted ranges due to urban growth, altitudinal gradients, or within narrow environmental gradients are particularly vulnerable (e.g., Bay checkerspot butterfly, Mount Hamilton thistle) because they likely have nowhere to move if their habitat becomes less suitable (Parmesan et al. 1999; Pimm 2001; Walther et al. 2002; Easterling et al. 2000; Shainsky and Radosevich 1986; Murphy and Weiss 1992; J. Hillman pers. comm. 2007).
- **Shifts in natural community distribution and composition.** Increases in disturbance events, such as fire or flooding, could increase the distribution of disturbance-dependent land cover type and plant species, such as redwood forest annual grassland, within the study area (Brown and Hebda 1998; Lenihan et al. 2003; Fried et al. 2004; California Climate Change Center 2006; Rogers and Westfall 2007).
- **Changes in species abundance.** The number or density of individuals found in a particular location may change triggered by changes in resource availability associated with an increase or decrease in precipitation (Walther et al. 2002; Lenihan et al. 2003; Millar et al. 2006; Pounds et al. 2006). Changes such as these may benefit one species at the expense of another.

The conservation strategy, reserve design, and monitoring and adaptive management program address the threat of climate change using a multi-level approach: landscape level, natural community level, and species level. This

approach focuses on protecting and enhancing a range of natural communities, habitat types, and environmental gradients (e.g., altitude, aspect, slope), as well as other features that are important, as availability of resources and habitat types in the study area changes with climate change. More details on the effects of climate change to the study area and covered species, and the Plan's anticipation of these effects, are found in **Appendix F**.

### 5.3.3 Grassland Conservation and Management

#### Biological Goals and Objectives

The overarching biological goal for grasslands is to maintain and enhance functional grassland communities that benefit covered species and promote native biodiversity. Specific objectives within the Reserve System entail protection of serpentine grassland, other native grasslands, and other endemic features of the community such as serpentine seeps and serpentine rock outcrops. An additional objective is to ensure that a diversity of soil types and other environmental gradients are acquired in areas suitable for enhancing native species. Grasslands will be enhanced by reducing cover and biomass of nonnative invasive species and by increasing the diversity of native plants. A final objective that will enhance the grassland natural community is to increase distribution of California ground squirrels to increase the prey base and burrow availability for covered species.

Grassland conservation and management is anticipated to benefit 18 covered species. Covered species use of the grassland natural community is varied. Wildlife use includes movement, foraging, breeding, and year-round habitat. The grassland natural community is known to provide primary and secondary habitat for plants. Bay checkerspot butterfly uses serpentine bunchgrass grassland as year-round habitat and may use other grassland types for movement habitat to move between serpentine grassland habitat patches (see Section 5.4.1 *Bay Checkerspot Butterfly*). California tiger salamander and California red-legged frog use grassland for upland and movement habitat (see Section 5.4.2 *California Tiger Salamander* and Section 5.4.3 *California Red-legged Frog*). Western pond turtle uses grassland as movement (see Section 5.4.5 *Western Pond Turtle*). Western burrowing owl uses grassland for foraging and breeding (see Section 5.4.6 *Western Burrowing Owl*). Tricolored blackbird uses grassland as year-round habitat (see Section 5.4.8 *Tricolored Blackbird*). San Joaquin kit fox uses grassland for movement and foraging (see Section 5.4.9 *San Joaquin Kit Fox*).

Serpentine bunchgrass grasslands and serpentine rock outcrop provides primary habitat for Tiburon Indian paintbrush, Santa Clara Valley dudleya, smooth lessingia, and Metcalf Canyon jewelflower (see Section 5.4.10 *Tiburon Indian Paintbrush*, Section 5.4.13 *Santa Clara Valley Dudleya*, Section 5.4.16 *Smooth Lessingia*, and Section 5.4.17 *Metcalf Canyon Jewelflower*). Serpentine bunchgrass grassland provides primary habitat for Coyote ceanothus and fragrant fritillary (see Section 5.4.11 *Coyote Ceanothus* and Section 5.4.14 *Fragrant*

*Fritillary*). Serpentine bunchgrass grassland and serpentine seeps provide primary habitat for Mount Hamilton thistle (see Section 5.4.12 *Mt. Hamilton Thistle*). Finally, serpentine bunchgrass grasslands and serpentine rock outcrops provides primary habitat and non-serpentine rock outcrops provides secondary habitat for most beautiful jewelflower (see Section 5.4.18 *Most Beautiful Jewelflower*). The grassland acquisition and enhancement conservation actions identified in the following sections are intended to benefit these species as well as the natural community.

## Acquisition and Enhancement

The Plan requires that the Implementing Entity acquire at least 17,300 acres of grassland through fee title or conservation easement (**Tables 5-11 and 5-18**).

### Grassland Acquisition

The Implementing Entity will protect, through fee title purchase or easement, at least 4,000 acres of serpentine bunchgrass grassland, 120 acres of serpentine rock outcrops/barrens, 10 acres of serpentine seeps (LAND-G1, **Tables 5-11 and 5-18**), 10 acres of rock outcrops, and 13,300 acres of annual grassland (LAND-G2, **Table 5-11**). Specific acquisition targets are not established for native grasslands because native stands intergrade with nonnative grasses and are generally not well documented or mapped in the study area. Land acquisition will prioritize those parcels with stands of native grasses. Perennial bunchgrass grassland will be prioritized for acquisition where it occurs (LAND-G2). The Implementing Entity will manage these lands as part of the Reserve System. These areas will be representative of the diversity of vegetation alliances, soil types, topography, elevation, and other environmental gradients in the study area.

The Implementing Entity will acquire all land by Year 45 according to the Stay-Ahead provision described in Chapter 8, Section 8.6.1 *Stay-Ahead Provision*. This provision requires that grassland preservation requirements be met prior to impacts occurring to each grassland land cover type, with a 10% allowable deviation.

Acquisition of serpentine grassland will occur primarily on Coyote Ridge from Silver Creek south to Anderson Reservoir. Large stands of serpentine grassland will also be acquired in the Santa Teresa Hills, near Chesbro Reservoir (Llagas-2), and north of Morgan Hill (Coyote-5 and Llagas-3). Land acquisition targets for serpentine grassland that are geographically specific (see **Table 5-19**) will ensure that the most valuable stands are acquired to support the covered species. Portions of several County parks expected to be incorporated into the Reserve System support large and important stands of serpentine grassland that will be managed more effectively: Santa Teresa, Calero, and Coyote Lake-Harvey Bear Ranch (**Table 5-5**).

Annual grassland will be acquired for the Reserve System on and near Coyote Ridge, near San Felipe Creek, in Upper Penitencia Creek watershed, in the Pacheco Creek watershed, north of Gilroy, and in the southwest corner of the study area (Uvas-5, Uvas-6, Pescadero-1). County parks with significant stands of annual grassland that will be incorporated into the Reserve System include Joseph Grant and Coyote Lake-Harvey Bear Ranch (**Table 5-5**).

## **Grassland Enhancement**

All grasslands in the Reserve System will be enhanced. Grassland enhancement will begin immediately after reserve unit management plans are completed or updated for each reserve unit. Native grasslands will be enhanced in the reserves using techniques tailored to the grassland type (i.e., the vegetation alliance) and the site. Each grassland stand will be classified to the alliance level according to the CNDDDB vegetation classification scheme (California Department of Fish and Game 2003).

Enhancement techniques and frequencies and intensities of application will be informed by pre-acquisition assessments, baseline surveys, and targeted studies (see Chapter 7). Grassland communities in the study area are mosaics of many vegetation alliances, as described in Chapter 3, and will occur throughout the Reserve System. The proper management regime necessary to maintain this mosaic of grassland types and enhance each grassland vegetation alliance will be determined through a combination of proven techniques such as moderate livestock grazing and small-scale experimental treatments, or pilot studies. Pilot studies will be initiated on small species levels to determine the feasibility of enhancement activities that, if successful, can be applied on a larger level. The pilot studies will test approaches to promote native grassland species and will be conducted as part of the monitoring and adaptive management program.

If monitoring demonstrates that the treatments are effective at increasing the relative cover of native grasses and forbs, the reserve manager will evaluate whether these treatments can be applied to the entire stand of the grassland vegetation alliance to achieve enhancement objectives of grassland on a larger scale. In some cases, management regimes could be shifted in time, location, or intensity to achieve these objectives. This evaluation must be conducted on a case-by-case basis in which the expected benefits to grassland are weighed against the environmental impact, hazard risk, and increased cost of applying the technique on a larger scale.

## **Management Techniques and Tools**

### **General Principles for Grassland Management**

Enhancing grasslands within Habitat Plan reserves will likely require applying many of the management techniques described below concurrently at different sites and on different scales to create a mosaic of grassland conditions. Applying

different management techniques across different spatial and temporal scales will maximize habitat heterogeneity across the landscape and will tend to increase native biological and structural diversity (Fuhlendorf and Engle 2001). For example, the buildup of dead plant material, or thatch, has been implicated in the suppression of native annual forbs in unmanaged wet grasslands in California (Hayes and Holl 2003). Techniques to reduce thatch (e.g., livestock grazing, prescribed burning, raking) will be applied only where the treatment is expected to benefit native grassland species. Techniques to reduce thatch should be discontinued if they are demonstrated to promote expansion of invasive species or encroachment of nonnative grassland into native grassland areas. These management techniques can also be effective at reducing the overall biomass of nonnative, invasive species and brush and increasing the annual success of native grassland species (LM-11).

Managers must consider the impacts of management treatments on other covered species. For example, if burns occur within grassland habitat, treatments may affect covered plants in both positive and negative ways (Gillespie and Allen 2004); accordingly, it is important to monitor several life stages to determine the net effect of management actions.

Site conditions (both physical and biological) and land use history are important in developing biologically appropriate management techniques to attempt to enhance native grassland alliances (Stromberg and Griffin 1996; Hamilton et al. 2002; Harrison et al. 2003). For example, some species of native grasses may occur primarily on steep north- or east-facing slopes where soil moisture tends to be higher (Jones & Stokes Associates 1989). Management strategies at these sites will differ from sites on more level topography and drier, south-facing slopes.

## Livestock Grazing

The flora of the study area evolved under the influence of prehistoric herbivores, including large herds of deer, elk, antelope, and other grazing animals, and without the competition from nonnative annuals which dominate much of the study area today. At present, appropriate livestock grazing utilizing cattle, sheep, and goats can be useful for range management, as a vegetation management tool to promote native plants and animals, and to reduce fuel loads for wildfires. In the study area, grazing has been shown to benefit most covered plant species and Bay checkerspot butterfly by reducing cover of invasive plants and increasing habitat for dwarf plantain, the butterfly's host plant (Weiss and Wright 2005, 2006; Santa Clara Valley Transportation Authority 2006; also see **Appendix D**). In addition, grazing and rangeland management practice have been demonstrated to benefit California tiger salamander and California red-legged frog. For these species, the USFWS issued a special Section 4(d) rule exempting ranch practices from a possible take because the benefit of these practices was deemed far greater than any potential individual loss.

Grazing may also benefit some ground-nesting or ground-foraging songbird species by providing variations in vegetative cover (Santa Clara Valley

Transportation Authority 2006). However, effects on all covered species are not quantified or fully understood, and it is possible that in some cases the effects of grazing on some covered plants may be detrimental (J. Hillman pers. comm.). Initially, vegetation management that is implemented will reduce the height of all vegetation to less than 12 inches (through grazing and mowing) (GRASS-8).

Grazing by livestock and native herbivores is a conservation action proposed for implementation in the Reserve System to enhance grasslands by creating structural diversity and increasing the abundance of native grassland species (GRASS-1). Several factors, including timing, stocking rate, rotation type, and grazing species, may affect the success of a grazing program (Sotoyome Resource Conservation District 2007). Tule elk may not be ideal native grazers on a large scale. Large herds of Tule elk may damage fences and disrupt livestock grazing programs (J. Fields pers. comm.). Fencing required to manage herds of Tule elk or other large herbivores may create barriers to wildlife movement.

Varying the timing (i.e., seasonal timing, annual timing) of grazing generally produces different effects across the landscape (Weiss 1999; Santa Clara Valley Transportation Authority 2006). A grazing treatment should be defined by the kinds and classes of livestock, their spatial distribution, their temporal distribution, and their density, and determines the effects of grazing on plants in the grazing area (Huntsinger, Bartolome, and D'Antonio 2007). For instance, researchers have observed that in serpentine grasslands, winter/spring grazing reduces annual grass cover more effectively than other grazing regimes (S. Weiss pers. comm.). While winter/spring grazing increases opportunities for dwarf plantain and other serpentine-adapted forbs, it can crush butterfly larvae, eggs, and pupae (Weiss 1999; Santa Clara Valley Transportation Authority 2006). Alternatively, summer/fall grazing may avoid butterfly larvae, eggs, and pupae; however the habitat created is not as high quality as that produced by the winter/spring regime (Santa Clara Valley Transportation Authority 2006; S. Weiss pers. comm.) Short-term winter grazing following burning may help to control exotic grasses as they germinate after winter rains, while mid-summer grazing may promote native perennial grasses because they are dormant at that time and not substantially damaged by grazing. These tradeoffs will need to be considered as reserve unit management plans are developed. For serpentine grassland, typical stocking rates and seasonality include 1 cow-calf per 10–15 acres for winter-spring (rainy season) or summer-fall (dry season), with small modifications according to short-term seasonal variations.

The stocking rate is the number of cattle grazing a given site for a given period of time. The stocking rate will be consistent with known or experimentally derived rates that promote native plants without adversely affecting covered species or causing long-term rangeland degradation. For example, excessive numbers of cattle in an area may trample Mt. Hamilton thistle, which occurs in serpentine soils in wet habitats such as serpentine seeps and springs, (J. Hillman pers. comm.) and Santa Clara dudleya, which occurs on serpentine rock outcrops (S. Weiss pers. comm.; J. Hillman pers. comm.).

Rotation of cattle on different pastures within and between years can influence the success of a grazing program. Grazing patterns and their effects on serpentine plants and insects are being tested on several sites in the study area, including Coyote Ridge and Tulare Hill. Current BMPs (Santa Clara Valley Transportation Authority 2006; S. Weiss pers. comm.; J. Fields pers. comm.) and research in various systems (Zervas 1998; Cousins et al. 2003) suggest that timing regimes should be consistent over long periods because frequent variation may increase nonnative cover and reduce habitat for native species. In view of this finding, consideration of historical patterns of currently grazed lands will direct decisions about grazing in the Reserve System. Current rotations will be monitored and only shifted if monitoring results indicate that the lands or covered species are adversely affected under the existing timing.

Different herbivorous species have different preferences and abilities to be selective grazers and therefore have different impacts on vegetation. Reserve unit management plans will take these differences into consideration.

Grazers will be excluded from some sensitive riparian areas (see Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management*). In addition, targeted studies examining grazing exclusion from specific terrestrial areas may be considered for sensitive plant species. However small-scale exclusion fences in potentially remote areas are expensive and labor intensive to install and maintain. Therefore, exclusionary fencing will only be considered in areas where monitoring indicates that conservation targets are not being met or detrimental effects of grazing may actually hinder the survival of the species.

Reintroduction of livestock grazing into areas where it has been excluded is an important conservation action of the Plan, particularly on serpentine grasslands. For example, livestock grazing will be reintroduced onto serpentine grassland sites in Santa Teresa County Park (**Table 5-5**) to reduce the biomass and diversity of nonnative grasses and herbs. Reintroduction of grazing is expected to substantially enhance habitat for Bay checkerspot butterfly and several covered plants. Recovery with the reintroduction of grazing may take many years, however, as evidenced in the Silver Creek Hills (Wetlands Research Associates 2008). On Tulare Hill, Weiss and colleagues have noted that seedbanks from the final large cohort of native forbs in 2004 (3 years after the cessation of grazing) provided for dense native forb cover following a June 2004 fire on Tulare Hill (Metcalf Energy Center 2006). Once the native seedbank is depleted, restoration of high-quality serpentine grassland requires recolonization from forb-rich patches of thin soils, which is a much slower process.

In view of the uncertainty of relevant research results, it would be prudent to use grazing management at sites with high potential to improve existing stands of native grasses and other targeted species, and to focus on reduction of the non-native species competition in a heterogeneous pattern—some patches grazed more and some less. Such grazing would favor a diversity of conditions, including those more favorable to expansion and persistence of the natives (Fuhlendorf and Engle 2001). Extensive grazing of large pastures with the livestock dispersed for the entire grazing period will be more effective at producing such heterogeneity than would higher intensity rotational grazing of

smaller pastures. Recent research by Bartolome (2011) shows that undisturbed annual grassland patches with abundant native grasses are low in phosphorous, and the opposite is found at adjacent sites where no native grasses occur. Determining the potential of grassland sites for improvement in native grass abundance may be accomplished by correlating site conditions where native grasses are abundant, soil patches have low productivity, and soils have not been disturbed. Such determinations may be confirmed by analyses of phytolith evidence of prehistoric grasslands and perennial grasses (Bartolome and Evett 2010). Management treatments to improve native grass abundance should be focused only at grassland sites that have the indicators of potential, but do not already support abundant native grasses.

## Prescribed Burning

Prescribed burning as a strategy to manage grasslands has been studied extensively in California and elsewhere (Harrison et al. 2003; Rice 2005). A review of existing literature in 2004 found that burning has mixed results depending on the starting condition of the ecosystem and on the timing and frequency of the burns (Rice 2005). Research indicates that in order for fire to successfully reduce nonnative and increase native plant cover, burns must be targeted toward the specific system and species conditions.

Prescribed burning is a conservation action to enhance natural communities, to control or eradicate invasive plants, and prevent natural community type conversion (GRASS-2). If burns are implemented in the Reserve System as a management tool, considerations will include the blooming and seeding times of the targeted nonnative species, the history of site use, and the likely condition of the native soil seed bank. Fires will be conducted at a time when the seeds of the targeted invasive plants will be destroyed. Single burns are generally unsuccessful at restoring native diversity and cover to grasslands; multiple burns are usually required. Burning can be used in conjunction with grazing or mowing to control infestations of invasive species and brush. If native vegetation on a site has been particularly denuded, supplementary seeding of native species may be required.

In particular, prescribed burning within the Reserve System may be an effective tool to eradicate exotic invasive species that are selectively avoided by grazing livestock. An example of this is barbed goatgrass (*Aegilops triuncialis*), a species that recently invaded Coyote Ridge and seriously threatens serpentine grasslands in the study area (S. Weiss pers. comm.). Barbed goatgrass is avoided by livestock but can be controlled with prescribed burns that are appropriately timed (just after plants senesce but while seeds are still maturing) and repeated (probably at least 2 or 3 years in succession) (DiTomaso et al. 2001). A pilot project to eradicate barbed goatgrass through burning that was initiated in 2006 on Coyote Ridge has shown mixed results (S. Weiss pers. comm.). Additional burns occurred in 2007.

Prescribed burns have been conducted by State Parks in Henry W. Coe State Park and by the Open Space Authority on several parcels. Prescribed burns have been

conducted by County Parks at Joseph Grant, Motorcycle, Mount Madonna and Santa Teresa County Parks (D. Rocha pers. comm.). County Parks plans to conduct prescribed burns in Coyote Lake–Harvey Bear Ranch County Park in the future (Rana Creek Habitat Restoration 2004). Prescribed burns in the Reserve System will be planned and conducted using the techniques and lessons learned from these agencies on actual burns.

In areas that are deemed *No-Burn* areas, the Implementing Entity will utilize management strategies that mimic the affects of burning on grassland species (e.g., mowing, hand pulling, targeted herbicide application) (LM-9).

## Mowing

In some instances, mowing is a reasonable alternative to prescribed burns; mowing is a conservation action for selected areas when grazing is infeasible (LM-11, GRASS-3). Mowing can often be safer and easier to implement on small scales than fire. Like prescribed burning, mowing needs to be timed to target the blooming/seeding cycle of nonnative species. Mowing may be particularly useful and effective as a small-scale treatment in areas that cattle cannot or should not access or for other site-specific logistical reasons (for example, when removal of vegetation is required at a time other than when livestock are available). Discing as a management tool in grasslands is not recommended because it often destroys burrows for covered and other native species (e.g., western burrowing owl, San Joaquin kit fox), increases soil erosion, and creates invasion sites for noxious weeds.

## Seeding Native Forbs and Grasses

In order to protect genetic integrity of the local landscape and ecosystems it is recommended that natural revegetation of local ecotypes should be encouraged first by controlling weeds and non-native species and seeding of native species should only occur in areas where natural revegetation is unlikely to occur (California Native Plant Society 2001). Highly degraded grasslands; however, may need additional input of native seed to restore their functionality. Seeding of native forbs and grasses is a conservation action in support of grassland enhancement (GRASS-4). Seeding may include covered plant species. Where possible, seed sources of covered plants will come from the project site itself and, if unavailable from the project site, from adjacent or nearby sites within the same watershed (California Native Plant Society 2001). If no seed source is available from the same watershed, then the seed source will be from as close as possible. Decisions regarding where to introduce seed and from how far away to collect it will be made in light of all available information about the targeted species, the source population, and issues related to maintaining the genetic integrity of existing populations (California Native Plant Society 2001).

To maximize the success of seed addition, pretreatment (e.g., burning 1 year prior to seeding to reduce weed seeds on the surface and in litter) may be

required. Recent research conducted on serpentine grasslands in Santa Barbara suggests that seedlings of California native forbs can be excellent competitors when enough seeds are present to overcome the dominance in the seed pool of the exotic grasses and forbs (Seabloom et al. 2002). In a 5-year experiment, burning or mowing had no effect on the abundance or the proportion of native forbs without seeding. Targeted studies could test this approach by seeding grasslands with native and locally collected seeds within the reserves.

## Ground-Dwelling Mammals

California ground squirrels play a key role in the grassland natural community. They provide a prey base for raptors and other covered species such as San Joaquin kit fox. In addition, their burrows provide nest sites for burrowing owls, (although their name implies otherwise, burrowing owls do not typically excavate their own burrows) and refugia for covered amphibians.

Historically, hunting and rodenticides have been used to control rodents and reduce conflicts with livestock. These practices may have decreased the populations of rodents, reducing prey availability for their predators. For example, in 1975 California ground squirrel, one of the main prey items for San Joaquin kit fox, was severely reduced in Contra Costa County after extensive rodent eradication efforts (Bell et al. 1994). The history of rodent control in Santa Clara County is unknown.

Under the Plan, a conservation action proposes to minimize existing rodent control measures (e.g., poisoning, hunting, and trapping) in reserves (GRASS-5). Minimizing existing ground squirrel control measures may be sufficient to increase squirrel populations in some areas. However, some rodent control measures will likely remain necessary in certain areas where dense rodent populations may compromise important infrastructure (e.g., pond berms, road embankments, railroad beds, levees, dam faces). The use of rodenticides or other rodent control measures will be prohibited in reserves except as necessary to address adverse impacts on essential structures within or immediately adjacent to reserves, including recreational facilities incorporated into the Reserve System. In addition, the Implementing Entity will introduce livestock grazing where it is not currently used, and where conflicts with covered activities will be minimized, to reduce vegetative cover and biomass that currently excludes ground squirrels to encourage ground squirrel colonization of new areas within the Reserve System (GRASS-6).

## Threats and Uncertainties

While focusing on management of nonnative invasive species, the Implementing Entity must also have management practices in place to recognize and account for invasions of nonnative species that have not been previously documented in the study area. When a new invasion is documented, an analysis of the threat it poses to native species and the current extent of the invasion will be conducted in

accordance with the invasive plant component of the reserve unit management plan for the Reserve System. In addition, coordination with local, regional, and state-level weed management programs will ensure that new invasions are caught early and their impact on native species minimized. With foreseeable changes in climate, the threat of invasive plants and animals is expected to increase.

Another threat to grasslands, serpentine grasslands in particular, is the ongoing and increasing nitrogen deposition from air pollution (Weiss 1999; California Energy Commission 2006; see **Appendix E**). Nitrogen deposition is predicted to increase during and beyond the term of the Plan due to population growth in the region and from covered activities (although it could possibly decrease if future automobile technologies address this issue; see Chapter 4 and **Appendix E** for details). Serpentine soils are inherently nutrient poor and are particularly limited in available nitrogen. Most serpentine-endemic plant species have evolved to tolerate this condition, while competitive invasive species cannot do so. This nutrient deficiency is believed to be the primary mechanism by which serpentine soils retain a high degree of native diversity (Harrison 1999). Nitrogen deposition has been shown to greatly increase available nitrogen in the soils of the study area and in turn to potentially increase the success of plant invasions into serpentine areas (Weiss 1999). The same study also found that serpentine areas that are grazed do not suffer the same plant invasions, most likely due to the fact that cattle selectively graze the invasive grasses and leave the native species and also because the cattle effectively remove nitrogen from the site (Weiss 1999). Continued active management using livestock grazing, prescribed or natural burning, and other methods will therefore be essential to offsetting the potentially increasing threat of nitrogen deposition in this community. The long-term effects of N-deposition are unknown, but the working hypothesis is that existing grazing regimes will be able to maintain native biological diversity.

## **5.3.4 Chaparral and Northern Coastal Scrub Conservation and Management**

### **Biological Goals and Objectives**

The biological goals and objectives for chaparral and northern coastal scrub communities include enhancement to benefit covered and other native species. The Implementing Entity will accomplish this by protecting land that supports chaparral and northern coastal scrub land cover types through fee title purchase or conservation easement and managing that land as part of the Reserve System. Areas that are protected will contain the full range of chaparral and northern coastal scrub community vegetation associations. An additional objective is to promote regeneration and succession. These natural processes will in turn benefit native species that occur in these land cover types. Acquisition, enhancement, and management actions to achieve these goals are discussed below.

Chaparral and northern coastal scrub conservation and management are anticipated to benefit 15 covered species. Covered species use of the chaparral and northern coastal scrub natural community is varied. Wildlife species use includes upland, movement, and foraging habitat. Chaparral and northern coastal scrub also provide primary and secondary habitat for some covered plant species. Additional details on species specific conservation actions can be found in each of the species sections identified below; however, the following is a summary of covered species use of the chaparral and northern coastal scrub natural community.

Bay checkerspot butterfly uses chaparral and coastal scrub as movement habitat to move between serpentine grassland habitat patches (see Section 5.4.1 *Bay Checkerspot Butterfly*). California tiger salamander uses chaparral and coastal scrub as upland and movement habitat (see Section 5.4.2 *California Tiger Salamander*). California red-legged frog and western pond turtle use chaparral and coastal scrub as movement habitat (Section 5.4.3 *California Red-legged Frog* and Section 5.4.5 *Western Pond Turtle*). Mixed serpentine chaparral serves as primary habitat for Coyote ceanothus (see Section 5.4.11 *Coyote Ceanothus*). Northern sage scrub/ Diablan sage scrub provides secondary habitat for fragrant fritillary (see Section 5.4.14 *Fragrant Fritillary*). Chaparral provides secondary habitat for Loma Prieta hoita (see Section 5.4.15 *Loma Prieta Hoita*). Mixed serpentine chaparral as primary habitat and northern coastal scrub/ Diablan sage scrub provides secondary habitat for Most beautiful jewelflower (see Section 5.4.18 *Most Beautiful Jewelflower*). The acquisition and enhancement conservation actions identified in the following sections are intended benefit the species identified above and contribute to species recovery, as well as benefit the natural community.

## Acquisition and Enhancement

During Plan implementation, the Implementing Entity will protect, through fee title purchase or conservation easements, at least 2,500 acres of chaparral and northern coastal scrub (**Table 5-11**).

### Chaparral and Northern Scrub Acquisition

The Implementing Entity will acquire at least 400 acres of northern mixed chaparral/chamise chaparral (LAND-C1), at least 700 acres of mixed serpentine chaparral (LAND-C2), and at least 1,400 acres of northern coastal scrub/Diablan sage scrub (LAND-C3) (**Table 5-11**).

The Implementing Entity will acquire all land by Year 45 according to the Stay-Ahead provision described in Chapter 8, Section 8.6.1 *Stay-Ahead Provision*. This provision requires that chaparral and scrub preservation requirements be met prior to impacts occurring to each land cover type, with a 10% allowable deviation.

Acquisition of northern mixed chaparral/chamise chaparral will occur primarily in the Diablo Range in the Pacheco watershed. In the Santa Cruz Mountains, this land cover type is restricted to upper watersheds, so acquisition would occur primarily in Llagas-1, Uvas-1, and Pescadero-1. Acquisition of mixed serpentine chaparral will occur throughout the study area, but primarily on Coyote Ridge. Large stands of serpentine chaparral targeted for preservation are also present in the Santa Teresa Hills (Guadalupe-1), near Chesbro Reservoir (Llagas-2 and Uvas-1), and in the Pacheco watershed. Acquisition of northern coastal scrub/Diablan sage scrub will occur in the Diablo Range near San Felipe Creek and south of Henry W. Coe State Park. In the Santa Cruz Mountains, acquisition of northern coastal scrub/Diablan sage scrub will occur primarily near Pescadero Creek.

## Chaparral and Northern Scrub Enhancement

All chaparral acquired for and incorporated into the Reserve System (for the latter, see **Table 5-5**) will be enhanced. Chaparral and northern coastal scrub enhancement will begin immediately after reserve unit management plans are completed or updated for each reserve unit.

Enhancement techniques and frequencies and intensities of application will be informed by pre-acquisition assessments, baseline surveys, and targeted studies (see Chapter 7). Enhancement of chaparral and northern coastal scrub will occur by maintaining or reestablishing natural disturbances such as fire. This will create a mosaic of chaparral and northern coastal scrub stands with varying ages since the last fire, promoting native biological diversity and long-term persistence of this community. However, reestablishing fire through prescribed burning or wildfires will only be possible away from urban or rural areas to minimize risk to human health and structures.

As described in Chapter 3, chaparral and northern coastal scrub are dependent on periodic fires to maintain natural processes such as succession and regeneration. These processes ensure native species diversity and help reduce invasion by nonnative species. Some chaparral species require fire stimulation of the seedbank in order to regenerate. The natural fire frequency and intensity in chaparral and northern coastal scrub habitat is not well understood in the study area, and the effects of prescribed burns on species typically associated with these habitats is unknown. Enhancement of chaparral will involve an investigation of the use of fire to create structural diversity and/or other techniques that mimic the effects of fire.

The Implementing Entity will seek to address uncertainties regarding the enhancement of chaparral and northern coastal scrub through an adaptive management approach and through the monitoring program described in Chapter 7. Targeted research will be conducted to determine factors relevant to the health and regeneration of native chaparral/scrub species (STUDIES-2).

## Management Techniques and Tools

Biologically appropriate management techniques will be determined on a site-specific basis and may include those listed below.

- Minimum impact fire suppression techniques (described above in Section 5.3.2 *Landscape Conservation and Management* subheading *Fire Management*).
- Prescribed burning.
- Mechanical or hand clearing.

### Prescribed Burning

Where feasible, the Implementing Entity will conduct prescribed burns in chaparral and northern coastal scrub to maintain canopy gaps and promote regeneration (CHAP-1). Prescribed burns may also be needed on portions of the Reserve System closest to urban and suburban areas to reduce the risk of catastrophic wildfires. This management technique is based on four key assumptions: (1) the current fire-return interval in chaparral is longer than historic levels due to modern fire suppression, (2) new growth is lacking and dead material has increased, (3) vegetation density has increased as a result of fire suppression, and (4) this increase in vegetation density has increased the risk of high-intensity fire.

Prescribed burning in chaparral may reduce wildfire risk at some sites, but this benefit will be balanced with the consequences of fires that are too frequent. Fires that occur too frequently in chaparral may reduce chaparral biological diversity by eliminating species not adapted to frequent burning (Zedler et al. 1983). Chaparral that experiences frequent fires is exposed to high rates of erosion, which may damage watershed functions.

Prescribed fires in chaparral should be conducted in late fall or winter when weather conditions maximize the ability of fire crews to control the fire. Burns conducted at that time will exert less effect on the seed banks and reproductive capability of exotic plants. Fall and winter burns will be conducted carefully in order to minimize excessive mortality of native seed banks than can result from lengthy smoldering fires in wet soil conditions (Le Fer and Parker 2005).

### Mechanical/Hand Thinning

In areas where burning is not possible, other types of management will be implemented to increase structural diversity (e.g., canopy gaps, variety of stand ages). Mechanical or hand thinning may be used to promote structural diversity in these land cover types (CHAP-2). In addition, these management activities may be used prior to prescribed burns to reduce the chance that the fire will burn too hot and damage the seed bank, or that the fire will escape control due to heavy fuel loads.

## Threats and Uncertainties

Many land management plans recommend rotational burning of chaparral and other shrublands to maintain a mosaic of stand ages, providing the maximum benefit to these communities and minimizing the chances of catastrophic wildfire. However, recent research suggests that the assumptions on which these policies are based are erroneous for chaparral communities in southern California (Keeley 2002) and may be erroneous for chaparral communities in central and northern California as well (Keeley 2005). The frequency of fire in southern California shrublands has been as frequent or more frequent in the twentieth century than it was in the nineteenth century (prior to fire-suppression activities), partly because fire-suppression activities have been ineffective at reducing fire frequency in shrublands (Keeley et al. 1999; Keeley and Fotheringham 2001). This pattern appears to hold true in Santa Clara County. Between 1950 and 1985, fire frequency in the county increased significantly, then leveled off and held steady through 2005, despite dramatic population growth in the region (Keeley 2005). Thus, fire suppression has not prevented fires but has been successful at maintaining their frequency and size, despite the increase in ignition sources (i.e., people).

Fire hazard in chaparral habitat appears to be either independent of, or only weakly dependent on, stand age for the first 20 years after fire (Schoenberg et al. 2003). The frequency of severe weather conditions (e.g., low humidity, high winds, and drought) and the number of people with access to stands (providing an ignition source) appear to play much more important roles than do vegetation conditions in determining fire risk. This appears to be true in Santa Clara County, where more than 95% of fires (for the period 1945–2002) were ignited by humans rather than lightning (Keeley 2005). In fact, 60% of the years during that period experienced no lightning-caused fires at all.

Due to the level of uncertainty in managing chaparral and northern coastal scrub communities, some of the management will be undertaken experimentally (STUDIES-2), and changes to the type and frequency of management in all areas will be made through adaptive management.

In some areas, the dynamics of how chaparral or northern coastal scrub interacts with adjacent land cover types is unknown or not well understood. An example is the encroachment of Douglas-fir into chaparral communities on Mt. Tamalpais in Marin County, California. This encroachment is facilitated by the below-ground associations of fungi and plant roots (Horton et al 1999). The Implementing Entity will determine how other communities, such as grassland, oak woodland, and Douglas-fir forests, are affecting chaparral and northern coastal scrub and, as indicated by targeted studies and informed by the monitoring and adaptive management program, work to reduce that impact (CHAP-3).

## 5.3.5 Oak and Conifer Woodland Conservation and Management

### Biological Goals and Objectives

During Plan implementation, the Implementing Entity's goal will be to maintain and enhance oak and conifer woodlands to benefit covered and other native species. The Implementing Entity will accomplish this by protecting land that supports valley oak woodland, mixed oak woodland and forest, coast live oak forest and woodland, blue oak woodland, foothill pine-oak woodland, mixed evergreen forest, redwood forest, and knobcone pine woodland through fee title purchase or conservation easement and enhancing and managing that land as part of the Reserve System.

Areas that are protected will support the full range of oak or conifer woodland community associations found in the study area. Once protected, an additional objective is to enhance oak woodlands using specific management actions to promote regeneration that will in turn sustain beneficial processes and native species diversity. Objectives for conifer woodlands include creating and maintaining the appropriate structure, density, and species composition needed to sustain the natural processes and native species diversity that is typical of these communities. Those management actions are discussed below.

Oak and conifer woodland conservation and management are anticipated to benefit 16 covered species. Wildlife species use includes upland, movement, year-round, breeding and foraging habitat. Oak and conifer woodlands are known to provide primary and secondary habitat for covered plant species. Additional details on species specific conservation actions can be found in each of the species sections identified below; however, the following is a summary of covered species use of the oak and conifer woodland natural community.

Bay checkerspot butterfly uses oak woodlands as movement habitat to move between serpentine grassland habitat patches (see Section 5.4.1 *Bay Checkerspot Butterfly*). California tiger salamander uses oak and conifer woodlands as upland and movement habitat (see Section 5.4.2 *California Tiger Salamander*). California red-legged frog and western pond turtle use oak and conifer woodlands as movement habitat (Section 5.4.3 *California Red-legged Frog* and Section 5.4.5 *Western Pond Turtle*). Western pond turtle uses redwood forest as year-round habitat. Western burrowing owl uses valley oak woodlands for foraging and movement (see Section 5.4.6 *Western Burrowing Owl*). Tricolored blackbird uses valley oak woodlands as year-round foraging habitat (see Section 5.4.8 *Tricolored Blackbird*). San Joaquin kit fox uses oak woodlands with low densities of trees, at lower elevations and with gentle slopes for movement and foraging (see Section 5.4.9 *San Joaquin Kit Fox*). Several oak woodland types provide primary habitat for Santa Clara Valley dudleya (see Section 5.4.13 *Santa Clara Valley Dudleya*). Oak woodlands provide secondary habitat for fragrant fritillary (see Section 5.4.14 *Fragrant Fritillary*). Oak and conifer woodland types are known to provide primary habitat, while others may

provide suitable habitat for Loma Prieta hoita (see Section 5.4.15 *Loma Prieta Hoita*). The acquisition and enhancement conservation actions identified in the following sections are intended be beneficial for the natural community and the covered species identified above and contribute to species recovery.

## Acquisition and Enhancement

During Plan implementation, the Implementing Entity will protect, through fee title purchase or conservation easement, at least 17,100 acres of oak woodland (**Table 5-11**). In addition, the Implementing Entity will protect at least 500 acres of conifer woodland.

### Oak and Conifer Woodland Acquisition

Of the total acquisition of 12,900 acres, valley oak woodland will account for 1,700 acres (LAND-OC3), mixed oak woodland and forest will account for 7,100 acres (LAND-OC1), coast live oak woodland and forest will account for 2,900 acres (LAND-OC2), blue oak woodland will account for 1,100 acres (LAND-OC3), foothill pine-oak woodland will account for 80 acres (LAND-OC4), and mixed evergreen forest will account for 20 acres (LAND-OC5) (**Table 5-11**).

The Implementing Entity will acquire all land by Year 45 according to the Stay-Ahead provision described in Chapter 8, Section 8.6.1 *Stay-Ahead Provision*. This provision requires that oak and conifer woodland preservation requirements be met prior to impacts occurring to each land cover type, with a 10% allowable deviation.

Acquisition of oak woodland land cover types will occur throughout the Santa Cruz Mountains and the Diablo Range. Acquisition of mixed evergreen forest, which is restricted to the Santa Cruz Mountains, will occur in the upper Llagas and Uvas watersheds (Llagas-1 and Uvas-1). Valley oak woodland is largely restricted in the study area to the Diablo Range; acquisition of this land cover type will occur where some of the largest stands are found in the Pacheco watershed (Pacheco-4, Pacheco-7, Pacheco-8), near San Felipe Creek (Coyote-4) and in the Alameda Creek and Upper Penintencia Creek watersheds (Alameda-1 and Coyote-7). Portions of County parks to be incorporated into the Reserve System that will permanently protect and allow improved management of large stands of oak woodland include Almaden Quicksilver, Anderson Lake, Calero, Coyote Lake-Harvey Bear Ranch, Joseph Grant, and Santa Teresa (see **Table 5-5** and below for which land cover types benefit).

Acquisition of conifer woodland land cover types is limited to 10 acres of redwood forest (LAND-OC6). Land acquisition requirements for conifer woodland are modest because there are limited opportunities to protect these land cover types within the study area.

## Oak and Conifer Woodland Enhancement

All oak and conifer woodland land cover types acquired would be enhanced as indicated by pre-acquisition assessments, baseline surveys, and targeted studies and informed by the monitoring and adaptive management program. Oak and conifer woodland enhancement will occur immediately after reserve unit management plans are completed or updated for each reserve unit. Enhancement will occur in both the Santa Cruz Mountains and the Diablo Range in all oak and conifer woodlands acquired and protected in the Reserve System. Enhancement of oak and conifer woodland may be appropriate at several specific locations, such as those listed below (**Tables 5-5 and 5-22**).

- Almaden Quicksilver County Park (mixed oak woodland, blue oak woodland, and mixed evergreen forest).
- Calero County Park (mixed oak woodland).
- Joseph D. Grant County Park (valley oak woodland, blue oak woodland, mixed oak woodland).

Enhancement in oak woodland or conifer woodland would be determined on the basis of site conditions and needs, and may include the measures listed below.

- Reducing the cover and density of invasive plants.
- Reducing or eliminating exotic wildlife such as wild pigs.
- Restoring natural processes such as fire or moderate levels of grazing.
- In some instances, restoring historic densities of trees through planting acorns or seedlings where they have been removed, where they are not regenerating naturally, or where densities are low relative to vigorous reference stands due to past land uses.

## Management Techniques and Tools

### Oak Woodland

Many factors may influence the population dynamics of oak woodlands within the study area (Pavlik et al. 1991). A site-specific assessment is required to determine the factors most limiting to stands in reserves, and management will be prescribed accordingly. The factor that may be most limiting to oak woodlands in the study area is a lack of oak regeneration due to a high density of nonnative invasive plants in the understory. A recent study of the effects of wild pigs in Joseph D. Grant County Park showed that pigs can disturb up to 35–65% of the ground annually where they occur in high densities, and that they significantly reduce acorn survival (Sweitzer and Van Vuren 2002).

Some studies have found that browsing by deer or livestock can negatively affect recruitment (Borchert et al. 1989; Bartolome et al. 2002), while others have found that grazing by small mammals (Tyler et al. 2002) is detrimental. The Implementing Entity will experimentally manage oak woodlands to reduce

seedling mortality; increase seedling and sapling survival; and determine factors relevant to regeneration, including browsing by mammals, birds, and insects (STUDIES-3). In some cases, fencing may be necessary around seed trees or stands of juvenile oaks to exclude native herbivores such as California ground squirrels, rabbits, or black-tailed deer until juvenile trees grow above the browse line.

One possible approach might be to manage oak stands in reserves using the decision-making process adopted by Cal-Fire (Jones & Stokes Associates 1988) and used for management of oak stands in the Los Vaqueros Watershed in eastern Contra Costa County (Brady and Associates 1997; Jones & Stokes Associates 1991; Contra Costa Water District 2001). If canopy coverage is declining, stands will be surveyed to determine if recruitment is adequate to replace lost trees and meet canopy coverage goals. The age structure of the tree population will also be considered to determine if stands may be increasing or in decline. If surveys indicate that recruitment is insufficient, management actions will be implemented to improve recruitment. Decision-making would be reassessed every five years.

To aid in oak regeneration, the Implementing Entity will eradicate feral pigs where feasible, and will reduce the overall number of pigs in the Reserve System through fencing, trapping, or other control methods (LM-12). Henry W. Coe State Park has been operating a successful pig-trapping program for several years (Sweitzer and Loggins 2001) and could be used as a model for the Reserve System.

The Implementing Entity will continue to employ livestock grazing in areas where nonnative vegetation is preventing successful oak regeneration and recruitment (GRASS-1). Modifying livestock stocking rates, timing of grazing, grazer species, or livestock access to certain areas may improve results in oak or conifer woodland. Where grazing is not feasible or not successful, the Implementing Entity will mow, hand clear, or selectively apply herbicides to reduce the nonnative vegetation in the understory of oak woodlands (GRASS-3, LM-14, LM-11). Prescribed burning may also be used in low-density oak woodlands to reduce nonnative invasive grass cover beneath oaks and encourage growth of a native understory and oak seedlings (OAK-1). Oak woodlands will also benefit from a let-burn policy within the study area. Both prescribed burns and the let-burn policy are described above in Section 5.3.2 *Landscape Conservation and Management*.

## Conifer Woodland

Conifer woodlands within the study area may have grown denser over time with the suppression of fire and lack of management. There are three types of conifer communities in the study area: redwood forest, knobcone pine woodland, and ponderosa pine woodland; however, the Plan only requires the protection of redwood forest. All but 5 acres of ponderosa pine woodland occur within Henry W. Coe State Park, which is outside of the permit area, and within San Felipe Ranch, which is protected by conservation easement. Although five acres of

ponderosa pine woodland are located within the permit area, just north of Henry Coe State Park, impacts to ponderosa pine woodland are not covered under this Plan because there are no opportunities to mitigate and conserve the natural community within the permit area (**Table 5-11**). Knobcone pine woodlands do not provide important habitat for the covered species; as such they are not targeted for acquisition.

Redwood forest require tailored management techniques based on forest condition, levels of regeneration, and on management goals. Management of redwood forest within the Reserve System will focus on retaining stands of more natural densities that will promote a more natural succession of native species in the understory and mid-canopy. At times this goal may entail some targeted thinning. As indicated by pre-acquisition assessments and targeted studies and informed by the monitoring and adaptive management program, that thinning will involve conducting the appropriate type of prescribed burns in redwood forest (OAK-2). When burning is not possible, other forms of mechanical thinning (e.g., cutting) will be selectively used to reduce the densities of trees in target areas to promote a healthy understory and mid-canopy (OAK-3). Whenever thinning takes place it will be carried out experimentally to determine the factors relevant to regeneration and maintenance; adaptive management will inform changes in this practice as experimental programs generate a body of knowledge (STUDIES-4).

In redwood forests, redwood trees regenerate by sprouting from the base and therefore do not require frequent burning to expose bare soil for regeneration. Management issues in this forest type instead often focus on the reintroduction of fire for fuel reduction, and on trying to create a late successional stage forest, mimicking the old growth forests (G. Gray pers. comm.). Big Basin State Park has one of the largest redwood burn programs in the world. They conduct prescribed broadcast burns in second growth forest to help thin it. They do not conduct mechanical thinning due to cost and the potential for damage to trees by equipment. In the North Coast Redwoods State Parks District, management techniques vary by stand conditions and age of the trees. They may remove redwoods if they are too close together. In old-growth forests, 30 trees/acre is common. In second-growth forests, there can be 200–1,000+ trees/acre. In these densely packed stands, a fire would kill most of the trees, so they often only do mechanical thinning to reduce the available fuel while retaining many of the trees (J. Harris pers. comm.). All of the redwood forest in the study area is second growth forest. Therefore, the Implementing Entity will conduct mechanical thinning or develop a prescribed burning program based on stand conditions. Further research will be conducted on how to best recreate late successional forests (STUDIES-4).

## Threats and Uncertainties

Substantially reducing the feral pig population in the Reserve System is an important long-term goal that will benefit all oak and conifer woodland natural communities. However, to be successful, such an effort must also be promoted on private and public land adjacent to, but outside of the Reserve System. This

will reduce the number of pigs immigrating into the Reserve System. An extensive trapping effort has proven successful in Henry W. Coe State Park in recent years, substantially reducing the feral pig population and the habitat destruction that the pigs cause (B. Patrie pers. comm.). It is evident that the feral pig population can be controlled but not eliminated in the Reserve System and that some level of damage to natural communities is likely to continue even with aggressive control measures.

## 5.3.6 Riverine and Riparian Forest and Scrub Conservation and Management

### Biological Goals and Objectives

The overarching biological goals for riverine and riparian habitats are to improve the quality of streams and the hydrologic and geomorphic processes that support them to maintain a functional aquatic and riparian community that benefits covered species and promotes native biodiversity. An additional goal is to maintain a functional riparian forest and scrub community at a variety of successional stages and to improve these communities to benefit covered species and promote native biodiversity. This includes specific objectives to protect and restore streams, riparian forest and scrub, and intermittent/ephemeral upper watershed tributaries within and outside the Reserve System. Land acquisition will target protection of key high-quality stream reaches and riparian woodland land cover types that provide habitat for covered species. Stream segments that could benefit from restoration will also be targeted for acquisition to allow the Implementing Entity to conduct physical and biological improvements to selected streams (actions that are often not possible on private land). Degraded streams and riparian woodland/scrub within the Reserve System will be improved to the maximum extent possible to increase overall ecological functions and values (i.e., species richness and diversity, vegetative cover, wildlife habitat function) and to enhance the ability of these habitats to support existing and new populations of covered species. Additional objectives focus on promoting community functions and habitat heterogeneity and connectivity, including specific targets for maintaining hydrologic and geomorphic stream processes.

Riverine (i.e., streams) and riparian forest and scrub mitigation includes a minimum preservation and restoration requirements to contribute to recovery and impact based mitigation ratios (see Section 5.3.1 *Land Acquisition and Restoration Actions*, subheading *Acquisition and Restoration Requirements for Aquatic Land Cover Types* for rationale). The Plan requires a minimum amount of preservation and restoration to occur regardless of the level of impact to riverine and riparian land cover types (**Table 5-13**). These minimum requirements ensure that the conservation goals of the Plan will be met even if all of the anticipated impacts do not occur. Minimum preservation requirements can be met through the acres preserved according to the preservation mitigation ratios (minimum acres preserved are not in addition to acres preserved according to the

preservation mitigation ratios). The rationale for this is that the preservation ratios include a recovery component as explained Section 5.3.1 *Land Acquisition and Restoration Actions*, subheading *Acquisition and Restoration Requirements for Aquatic Land Cover Types* where factors used to determine the preservation ratios are identified.

The preservation and restoration mitigation ratios for streams and riparian forest and scrub are additive (**Table 5-12**). For example, for every 1 mile of streams impacted, 3 miles must be preserved and enhanced (3:1) and 1 mile must be restored (1:1). This results in a mitigation ratio of 4:1 for all stream impacts. For every 1 acre of willow riparian forest and scrub or mixed riparian forest and woodland impacted, 2 acres must be preserved and enhanced (2:1) and 1 acre must be restored (1:1). This results in a mitigation ratio of 3:1 for all impacts to willow riparian forest and scrub or mixed riparian forest and woodland. For every 1 acre of Central California sycamore alluvial woodland impacted, 2 acres must be preserved and enhanced (2:1) and 2 acres must be restored (2:1). This results in a mitigation ratio of 4:1 for all Central California sycamore alluvial woodland impacts.

Regardless of the level of impacts, a minimum of 250 acres of riparian forest and scrub, 40 acres of Central California sycamore alluvial woodland, and 100 miles of streams must be preserved and enhanced to contribute to recovery (**Table 5-13**).

As explained above, the preservation mitigation counts towards the minimum preservation requirement. For example, the impacts to streams are capped at 9.4 miles. If all impacts occur, 28.2 miles of streams must be preserved and enhanced (3:1 preservation ratio). Since the minimum preservation and enhancement requirement is 100 stream miles, the Implementing Entity will be required to preserve and enhance an additional 71.8 stream miles ( $28.2 + 71.8 = 100$ ) to meet the minimum requirement, if all impacts occur. The minimum target of 100 miles of streams was determined to meet multiple needs: requirements for stream mitigation, preservation of habitat for foothill yellow-legged frog that would contribute to species recovery, preservation of habitat for California red-legged frog and western pond turtle that would contribute to species recovery (along with preservation of ponds and freshwater wetlands), and mitigation for temporary impacts (48.0 miles of impacts over the permit term). The Reserve System is expected to preserve substantially more than 100 miles of streams.

The same rationale applies to Central California sycamore alluvial woodland. If all impacts occur, 14 acres of Central California sycamore alluvial woodland must be preserved and enhanced (2:1 preservation ratio). Since the minimum preservation and enhancement requirement is 40 acres, the Implementing Entity will be required to preserve and enhance an additional 26 acres of Central California sycamore alluvial woodland ( $14 + 26 = 40$ ) to meet the minimum requirement, if all impacts occur. For willow riparian forest and scrub or mixed riparian forest, impacts are capped at 289 acres. If all impacts occur, 578 acres of willow riparian forest and scrub or mixed riparian forest must be preserved and enhanced. In this case, if all impacts occur, the minimum preservation and

enhancement requirement of 250 acres will be met by the mitigation ratio. If less than 125 acres of impacts occur, the Implementing Entity will still be required to preserve and enhance 250 acres to meet the minimum preservation requirement.

Riverine and riparian forest and scrub conservation and management are anticipated to benefit 12 covered species. Wildlife use includes movement, foraging, breeding, and year-round habitat. The riparian forest and scrub natural community is known to provide primary for one covered plant, Loma Prieta hoita (see Section 5.4.15 *Loma Prieta Hoita*). Bay checkerspot butterfly uses riverine and riparian forest and scrub natural communities as movement habitat to move between serpentine grassland patches (see Section 5.4.1 *Bay Checkerspot Butterfly*). California tiger salamander uses the riverine natural community for foraging and movement habitat and riparian forest and scrub as movement habitat (see Section 5.4.2 *California Tiger Salamander*). California red-legged and western pond turtle use riverine and riparian forest and scrub natural communities as year-round habitat (see Section 5.4.3 *California Red-Legged Frog* and Section 5.4.5 *Western Pond Turtle*). Foothill yellow-legged frogs use the riverine natural community as year-round habitat and the riparian forest and scrub natural community as foraging and movement habitat. Least Bell's vireo uses riparian forest and scrub as foraging and breeding habitat (see Section 5.4.7 *Least Bell's Vireo*). Tricolored blackbird uses the riparian forest and scrub natural community as breeding and year-round habitat (see Section 5.4.8 *Tricolored Blackbird*). San Joaquin kit fox may use low-density riparian forest and scrub as movement habitat (see Section 5.4.9 *San Joaquin Kit Fox*). The riparian forest and scrub acquisition and enhancement conservation actions identified in the following sections are intended to benefit these species and the natural community as a whole.

## Acquisition, Enhancement, and Restoration

Conservation of riverine habitats and riparian woodland and scrub combine land acquisition, habitat restoration, and habitat enhancement. All Reserve System lands will be enhanced. Each of these components is described below separately for riverine and riparian communities. Separate discussions are provided for organizational purposes only. Riverine and riparian woodland and scrub communities are closely tied to one another ecologically and both communities are often present in the same location. Land acquisition and restoration will be planned and implemented for both communities simultaneously for the same sites.

### Riverine Acquisition

Streams (riverine habitat) will be preserved in the permit area at a ratio of 3 stream miles to every mile affected (**Table 5-12**). An estimated 9.4 miles of stream is the most that would be permanently affected by covered activities. If this maximum level is reached, then at least 28.2 miles of stream would need to

be preserved. The minimum requirement of stream preservation, regardless of the level of impact, is 100 miles (**Table 5-13**).

During Plan implementation, the Implementing Entity will therefore protect at least 100 miles of stream (LAND-L3) (**Table 5-11**) according to the land acquisition priorities described in Section 5.3.1 *Land Acquisition and Restoration Actions* and below. All Reserve System lands will be enhanced.

All riverine protection will occur by Year 45 according to the Stay-Ahead provision described in Chapter 8, Section 8.6.1 *Stay-Ahead Provision*. This provision requires that stream preservation requirements be met prior to stream impacts occurring, with a 10% allowable deviation. Because streams are distributed widely throughout the study area, they will be part of nearly every land acquisition. The Implementing Entity will protect stream segments on key stream reaches through land acquisition (fee title or purchased conservation easement) or through landowner dedications through the Stream and Riparian Setback Condition when covered activities are proposed (see Chapter 6, Section 6.5, subheading *Condition 11 Stream and Riparian Setbacks* and **Figure 6-2**). Protection will provide opportunities to enhance habitat for native fish, covered amphibian and reptile species, and restore streams and riparian woodland and scrub. At a minimum, riverine acquisitions will include the following:

- Extending the Uvas Creek Park Preserve 1.6 miles upstream to Hecker Pass Highway and set back expected development adjacent to this stream segment to protect the Uvas Creek Corridor consistent with Goals 5-5, 5-7, and 5-8 of the approved City of Gilroy Hecker Pass Specific Plan (LAND-R1). The City of Gilroy Hecker Pass Specific Plan Goals 5-5, 5-7, and 5-8 are as follows:
  - *Goal 5-5: Extend the Uvas Creek Park Preserve and trail to the western boundary of the Hecker Pass Specific study area at the intersection of Uvas Creek and Hecker Pass Highway*
  - *Goal 5-7: Ensure the protection of Uvas Creek Corridor by establishing policies and protective measures for adjacent land uses.*
  - *Goal 5-8: Preserve and enhance the Uvas Creek corridor and the associated riparian habitat wherever possible.*
- At least 1.0 mile of Uvas Creek above Uvas Reservoir.
- At least 1.0 mile of Llagas Creek above Chesbro Reservoir. Pacheco Creek mainstem (2.0 miles) between Pacheco Reservoir and San Felipe Lake (LAND-R1).

Protected streams will include those in upper tributaries that have high sediment loads or other functional shortfalls that limit native fish productivity. Such streams have not been identified in the study area but likely include Bodfish Creek and Little Arthur Creek. Additional study will be needed in implementation to verify these assumptions and determine the locations of other functionally-limited streams.

## Riparian Acquisition

Willow riparian forest and scrub or mixed riparian forest and woodland would be acquired for the Reserve System, depending on the level of impact of covered activities (LAND-R2). Two acres of these land cover types would be acquired for every acre impacted by covered activities (2:1) (**Tables 5-13 and 5-21**). The Implementing Entity will protect, through fee title or conservation easement, a minimum of 250 acres of willow riparian forest and scrub or mixed riparian forest and woodland. If all impacts on these land cover types occur as predicted, then up to 578 acres would be acquired. Riparian woodland protection would occur primarily in north County on Upper Penitencia Creek, Upper Coyote Creek, and San Felipe Creek. In south County, riparian woodland protection would occur primarily on Uvas Creek, Bodfish Creek, Little Arthur Creek, Tar Creek, Pescadero Creek, Pajaro River, and Pacheco Creek and its tributaries (LAND-R2, LAND-R3). All Reserve System lands will be enhanced.

In addition to the riparian acquisition described above, a minimum of 40 acres of Central California sycamore alluvial woodland would be acquired for the Reserve System even though only 7 acres of impact are predicted (LAND-R2). This requirement is designed to ensure that this very rare and threatened land cover type (Keeler-Wolf et al. 1997) is adequately preserved in the study area.

All riparian woodland and scrub protection will occur by Year 45 according to the Stay-Ahead provision described in Chapter 8, Section 8.6.1 *Stay-Ahead Provision*. This provision requires that stream woodland and scrub protection requirements be met prior to impacts occurring to these land cover types, with a 10% allowable deviation.

## Riverine and Riparian Enhancement

All the riparian woodland/scrub and streams acquired and incorporated into the Reserve System would be enhanced, as indicated by pre-acquisition assessments and targeted studies and informed by the monitoring and adaptive management program. Up to approximately 592 acres of riparian woodland and scrub (including California sycamore alluvial woodland) and a minimum of 100 miles of stream will be enhanced in the Reserve System (**Tables 5-12 and 5-13**). Enhancement techniques are described below.

Habitat enhancement is the improvement of an existing terrestrial vegetation community or aquatic habitat. The overall goal of enhancement actions is to promote natural community functions and habitat heterogeneity and connectivity. Enhancement on streams and riparian woodland/scrub will occur throughout the Reserve System as indicated by pre-acquisition assessments and targeted studies and informed by the monitoring and adaptive management program.

Enhancement of riparian woodland and scrub will include enhancing the cover, density, structural diversity, and species diversity of riparian vegetation in the understory or small stream segments (STREAM-2).

Riverine and riparian enhancement will occur immediately after reserve unit management plans are completed or updated for each reserve unit.

## Riverine Restoration

Stream restoration would be accomplished according to the level of impacts on streams. One mile of stream would be restored for every mile of stream permanently affected by covered activities (**Tables 5-13 and 5-21**). A minimum of 1.0 mile of stream would be restored to contribute to species recovery (i.e., regardless of the level of stream impact). If all impacts occur, 10.4 miles of stream would be restored. Stream restoration would occur within the Reserve System and outside the Reserve System in partnership with private and public landowners as long as the conditions specified in Section 5.2.5 *Land Management*, subsection *Habitat Restoration* are met. The Implementing Entity would conduct additional site assessments during implementation to identify specific restoration project areas based on the site selection guidelines described below. Stream restoration techniques and guidelines are defined below.

Habitat restoration is the establishment of a vegetation community or aquatic habitat in an area that historically supported it, but no longer does because of the loss of one or more required ecological factors or as a result of past disturbance. Unlike other natural communities for which restoration is required, streams are unique—restoration occurs within the footprint of existing streams, rather than the creation of new ones, with some exceptions such as Fisher Creek, where the stream has been historically redirected. Stream restoration is defined as any substantial physical alteration to stream systems to return them to natural or semi-natural conditions and to restore specific ecological function in a site where that function has been lost (see Section 5.2.5 *Land Management* and **Appendix A** for definitions). For example, stream restoration includes removing hardscape features from concrete-lined or rip-rapped stream banks or restoring earthen or otherwise engineered channels to a more natural condition that allows for water infiltration, percolation, and groundwater recharge (STREAM-4). Restoration may also, when absolutely necessary, include stabilizing stream banks to manage fine sediment inputs and preventing excessive erosion (STREAM-6).

All stream restoration construction will be completed by Year 40 according to the Stay-Ahead provision described in Chapter 8, Section 8.6.1 *Stay-Ahead Provision*. All required stream restoration must be initiated (ground breaking) prior to impacts occurring to these land cover types. In addition, the Implementing Entity will complete stream restoration to contribute to species recovery according to the deadlines in **Table 5-14**.

## Riparian Restoration

Riparian restoration (STREAM-3) is required to offset any impacts on riparian woodland and scrub land cover types and to contribute to species recovery (e.g., least Bell's vireo). One acre of willow riparian forest and scrub or mixed

riparian forest and woodland, at a variety of successional stages, would be restored for every acre impacted by covered activities (**Table 5-12**).

Riparian restoration is defined as the re-establishment of riparian vegetation in areas where it has been severely degraded and once occurred. Stream restoration is defined for the purposes of this Plan as substantial physical modifications to stream banks or stream channels (see Section 5.2.5 *Land Management* and **Appendix A** for definitions). Riparian restoration and stream restoration may often occur together in the same location.

A minimum of 50 acres of willow riparian forest and scrub or mixed riparian forest and woodland would be restored in the Reserve System to contribute to the recovery of covered species and an estimated 289 acres would be restored to compensate for all impacts. Therefore, a total of 339 acres of these land cover types would be restored if all impacts occurred (**Tables 5-13 and 5-21**). Riparian restoration opportunities have not been evaluated in detail in the study area. Riparian restoration opportunities have been defined for Upper Penitencia Creek (Biotic Resources Group 2001) and within the City of San José (Jones & Stokes 2000).

Riparian restoration would occur within the Reserve System and outside the Reserve System in partnership with private and public landowners as long as the conditions specified in Section 5.2.5 *Land Management*, subheading *Habitat Restoration* are met. The Implementing Entity would conduct additional site assessments during implementation to identify specific restoration project areas based on the site selection guidelines described below. Site assessments are a necessary first step in the restoration design process and therefore will occur approximately one year before restoration projects are to be constructed in order to meet Stay-Ahead requirements and other deadlines (**Table 5-14**). The Implementing Entity would restore riparian woodland using techniques and guidelines described below.

An estimated 14 acres of Central California coastal sycamore alluvial woodland would be restored to compensate for the 7 acres of expected impacts (**Tables 5-13 and 5-21**). Opportunities for restoration of this land cover type are limited to locations where this land cover type can be supported (Keeler-Wolf et al. 1997). Examples include Pacheco Creek, Upper Coyote Creek, San Felipe Creek, and lower Uvas Creek.

Construction of all restoration of these land cover types will be completed by Year 40 and according to the Stay-Ahead provision described in Chapter 8, Section 8.6.1 *Stay-Ahead Provision*. All required restoration of riparian woodland and scrub must be initiated (ground breaking) prior to impacts occurring to these land cover types (see Section 8.6.1 for details). In addition, the Implementing Entity will complete restoration of riparian woodland to contribute to species recovery according to the deadlines in **Table 5-14** (Years 15, 30, and 40).

### **Guidelines for Selecting Restoration Sites**

Potential restoration sites in the study area will be evaluated in coordination with the other local agencies or organizations active in riparian restoration in the study area (e.g., SCVWD, The Nature Conservancy). As described in the Section 5.3.1 *Land Acquisition and Restoration Actions*, the Implementing Entity will likely be conducting most riparian restoration in the locations listed below.

- Coyote Creek and tributaries (including tributaries such as Fisher Creek and Thompson Creek).
- Alamitos Creek and tributaries.
- Los Gatos Creek below Vasona Dam
- Uvas and Carnadero Creeks (including tributaries such as Little Arthur Creek and Bodfish Creek), including reaches above Uvas Dam.
- Llagas Creek, particularly above Chesbro Dam.
- Pajaro River.
- Pacheco Creek.

Restoration sites will be selected according to criteria that include but are not limited to those listed below.

- The potential success of restoration activities, based on site-specific conditions (e.g., hydrology, soils).
- The ability of the site to support covered species after restoration.
- Historic conditions that supported or likely supported the target land cover type (San Francisco Estuary Institute 2007).
- The proximity of the site to the area in which streams or riparian woodland/scrub were (or are predicted to be) lost to covered activities.
- The proximity of the site to other intact riparian corridors that support, or are likely to support, covered species.
- The extent and quality of existing habitats (e.g., percent native vegetation and presence/absence of nonnative wildlife such as bullfrogs or cowbirds).
- Existing wildlife use and the potential for adverse effects of the restoration project (e.g., disturbance to or removal of existing wetland habitat).
- The ability of the restored stream and/or riparian woodland/scrub to contribute to the conservation goals of habitat connectivity in this Plan.

Riverine and riparian restoration sites will be selected using the best available assessments (e.g., Biotic Resources Group 2001 for Alum Rock County Park and Jones & Stokes 2000 for San José streams). Where assessments are not available, the Implementing Entity will, in coordination with the Wildlife Agencies, conduct detailed site assessments to determine the best available restoration sites.

### Site Restoration Plans

Detailed restoration plans, including plans and specifications, will be developed for individual sites or stream reaches based on specific geomorphic, hydraulic, and hydrologic conditions; extent and quality of existing habitats; existing wildlife use; and the potential for adverse effects (e.g., disturbance and/or removal of existing habitat or wetlands). Site restoration plans will be developed prior to construction of stream, riparian, and wetland restoration projects. These plans will be prepared consistent with the reserve unit management plan for the site<sup>26</sup>. Restoration plans will satisfy the requirements listed below.

- Define restoration goals and objectives, performance indicators, and success criteria.
- Collect and analyze baseline data (e.g., soil type and suitability for riparian planting, low-flow conditions, past land use history/alterations).
- Identify suitable/feasible restoration measures.
- Develop conceptual restoration designs.
- Develop detailed restoration designs (plans and specifications) that identify and describe construction methods, planting areas and methods, planting species (including collection and propagation methods), and maintenance requirements.
- Prepare an adaptive management and monitoring plan based on the guidelines in Chapter 7 that includes descriptions of responsible parties; monitoring methods and schedule; indicators (e.g., vegetative cover); success criteria (e.g., 20% cover by year 5); and adaptive management measures (e.g., replanting with different species).

## Management Techniques and Tools

### General Principles for Riverine/Riparian Management

Streams and adjacent riparian forest/scrub communities are dynamic habitats resulting from the confluence of hydrology with the geology, soils, and vegetation of the environment. The management tools discussed below will be used in concert to maintain natural or semi-natural functions or to achieve them in currently degraded communities. In many cases these techniques can also be used to manage existing high-quality habitats to the benefit of streams and riparian communities. Several guidance documents and local programs provide the basis for the selection and application of these management tools and techniques; these are listed below.

- *California Salmonid Stream Habitat Restoration Manual* (Flosi et al. 1998).
- *California Salmonid Stream Habitat Restoration Manual. Part XI, Riparian Habitat Restoration* (Circuit Rider Productions 2004).

<sup>26</sup> Site restoration plans on newly-acquired lands may be prepared prior to or concurrent with the reserve unit management plan.

- *Federal Stream Corridor Restoration Principles and Practices* (Federal Interagency Stream Restoration Working Group 1999).
- Three Creeks HCP (plan is pending)
- *Watershed Action Plan* (Santa Clara Basin Watershed Management Initiative 2003).
- Upper Llagas Creek Riparian Corridor Assessment (Tetra Tech, Inc. 2006).
- *Coyote Watershed Stream Stewardship Plan* (Santa Clara Valley Water District 2002c).
- *Stream Maintenance Program* (Santa Clara Valley Water District 2010).

Large riparian and stream restoration projects have been conducted or are planned in the permit area by SCVWD and other agencies along Guadalupe Creek, the Guadalupe River, Coyote Creek, Upper Penitencia Creek, and Llagas Creek. Project planning and construction documents and follow-up monitoring reports are excellent sources of information to guide future riparian and stream restoration and enhancement projects. Additional sources are provided below specifically for riparian restoration projects.

## In-Channel Habitat Management

In-channel habitat actions may include the complete restoration of the channel to remove anthropogenic features (e.g., concrete, earthen, or otherwise engineered channels), as well as enhancement actions that modify specific elements of in-channel habitat (e.g., large woody debris, gravel placement and cleaning, and laying back steep banks). Only in-channel restoration is covered in this section; each of the specific enhancement actions is covered in separate sections.

Formation and sustainability of riverine habitat is directly related to channel processes and channel form. Where these processes or forms are out of balance with their natural inputs or where they have been disturbed, restoration of the channel may be an appropriate technique to restore a sustainable natural channel and floodplain (STREAM-5).

The Implementing Entity will also reduce chronic anthropogenic sources of sediment and restore balanced input of substrate material within stream reaches. This will be accomplished through the implementation of conditions on covered activities that minimize inputs of fine sediment delivery to streams (STREAM-6; also see Chapter 6, Section 6.4.2, subheading *Condition 4 Stream Avoidance and Minimization for In-Stream Projects*). Stabilizing stream banks on selected reaches could also achieve this goal.

Channel restoration may entail direct restoration (reconstruction of a channel) or incremental process restoration (installation of a natural structural feature to induce change in a channel), consistent with the guidelines of the *California Salmonid Stream Habitat Restoration Manual* (Flosi et al. 1998; Circuit Rider Productions 2004). Channel restoration can also be used to restore bank stability

and reduce bank erosion; such restoration may improve aquatic habitat and water quality. Channel restoration techniques may affect the local slope, length, sinuosity, and dimensions of the channel, as well as alter basic channel processes related to sediment transport, and are very useful for treating the underlying causes of habitat degradation, as seen within the study area in the restoration of Guadalupe Creek upstream of the confluence with the Guadalupe River near Almaden Lake. Channel restoration under the Habitat Plan would only be considered as a potential solution where there are chronic anthropogenic problems. In implementation, the effects of restoration on local channel geometry will be carefully considered and proper hydraulic analysis performed (Flosi et al. 1998).

Under the Habitat Plan, the Implementing Entity will restore concrete, earthen, or other engineered channels as part of the 10.4 miles of stream restoration (STREAM-4).

## **Riparian Vegetation Management**

Successful implementation of riparian restoration can, over time, result in significant improvements in the cover and diversity of desirable native riparian plant communities.

An excellent example of successful riparian and stream restoration is the Guadalupe Creek restoration project. The project combined channel realignment with retention of existing vegetation, extensive riparian enhancement plantings and placement of in-stream woody debris along more than 12,000 linear feet of the creek. The project was completed in 2002. As of 2007, the riparian vegetation has developed into a multi-storied canopy, indicative of a healthy riparian corridor.

Establishment and recovery of native riparian plants will be faster in sunny, low-elevation, or moist sites than in shady, higher-elevation, or arid sites. However, advantageous growing conditions can also trigger rapid establishment of weedy or undesirable aggressive species; accordingly, weeds at and upstream of project sites will be evaluated before implementation of any treatments. Invasive plant removal will continue until desirable riparian vegetation is established and target invasive plants are substantially eradicated (i.e., greater than 50% eradicated and not expanding in range).

Use of riparian management techniques will consider the land use setting—that is, whether the site is in an urban, agricultural, or wildland environment. Some riparian management treatments may be appropriate in one type of setting and not in another. For example, the allowable height of vegetation may be constrained by its proximity to utilities, to address safety concerns, or to preserve views.

When placing plant materials, fences, offsite watering facilities, plant irrigation systems, and other materials in the riparian zone, the effects of flood flows (e.g., deposition of sediments and debris, scour) must be taken into account. It may be

necessary to install such facilities outside the flood prone area. To address these issues, vegetation management techniques will be developed in consideration of the recommendations presented in Part XI, *Riparian Habitat Restoration*, of the *California Salmonid Stream Habitat Restoration Manual* (Circuit Rider Productions 2004). Irrigation systems may be necessary to help establish riparian vegetation temporarily. However, these systems will be installed so that they can be removed (or left in place non-functioning) once the vegetation becomes self-sustaining and no longer requires supplemental irrigation.

The Implementing Entity will develop a successional management strategy for riparian vegetation communities to ensure that a diverse cross section of successional stages is fostered in the riparian corridor to promote natural stream functions during the permit term. This management strategy will be incorporated into the reserve unit management plans prepared according to Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management*. Reserve unit management plans must be prepared within 5 years of acquisition of the first parcel in the reserve unit.

The management strategy for successional riparian vegetation would be of greater importance downstream of reservoirs, where altered flow regimes reduce flood flows and the frequency and intensity of droughts, which would otherwise produce a mosaic of successional stages over time. This strategy may include such actions as girdling trees, moving gravel, or other techniques of managing physical process and vegetation to ensure a variety of successional stages of riparian forest and scrub land cover types. Development of the successional management strategy will be undertaken in consideration of existing plans in the study area, which can vary with the goals of the implementing agency and the context of the stream. Existing plans that could be used to inform this management strategy are listed below.

- *Coyote Creek Parkway County Park—Final Integrated Natural Resources Management Plan and Master Plan* (County of Santa Clara Parks and Recreation Department 2007).
- *Alum Rock Park Riparian Management Plan* (Biotic Resources Group 2001).
- *Riparian Restoration Action Plan for the City of San José* (Jones & Stokes 2000).
- *Stream Maintenance Program* (Santa Clara Valley Water District 2010).
- *Guidelines and Standards for Land Use Near Streams* (Santa Clara Valley Water District 2006).

## **Invasive Species Management**

The Habitat Plan includes objectives to reduce or remove invasive plant and fish species from stream channels to encourage establishment of native plant and wildlife species. Invasive species management will comprise existing actions under SCVWD's existing Stream Maintenance Program and additional actions under the Habitat Plan that are consistent with the Stream Management Program

and the Santa Clara County Integrated Pest Management Program and Pesticide Use Ordinance (Section B28-10). Invasive species management is described above in Section 5.3.2 *Landscape Conservation and Management*.

## **Livestock Management**

As part of the grazing management program (see Section 5.3.3 *Grassland Conservation and Management*) the Implementing Entity will exclude livestock along targeted stream segments (e.g., Pacheco Creek, floodplain of Coyote Creek) using exclusion fencing, off-channel water sources, and other potential actions as needed. This program will be implemented within the Reserve System and could be implemented outside the Reserve System if appropriate willing partners are identified.

## **Private Landowner Education**

The Implementing Entity will develop Stream Management (Riparian Land Use) Guidelines for private landowners, and an educational program to assist in the implementation of the guidelines, within five years of permit issuance. Details are found in Section 5.3.2 *Landscape Conservation and Management* subheading *Public Education and Outreach* above.

## **Threats and Uncertainties**

Within the study area, the San Francisco Regional Board is developing Total Maximum Daily Loads (TMDLs) for mercury and diazinon that could influence the implementation of covered activities and the conservation strategy related to riverine habitats in the Guadalupe River watershed. Instream activities within the Guadalupe watershed (e.g., stream crossings, bank stabilization activities, barrier removal, and stream enhancement and restoration projects) could increase the methylation of mercury that is found in sediments resulting from historic mining operations in the watershed. Final targets and strategies related to mercury TMDLs in the study area will affect the Local Partners' (especially SCVWD's) management of sediment in streams and will potentially affect the cost of restoration and enhancement opportunities in the Guadalupe watershed.

Availability of water from Central Valley Project facilities currently substantially supplements water supply in north county streams. The impact of climate change on the availability of this water is critical to the Habitat Plan conservation activities. In addition, Sacramento-San Joaquin Delta water quality and endangered species concerns (delta smelt and central valley salmon and steelhead) are affecting, and will continue to affect to an unknown degree, the timing and amount of water diversions from the delta. Any loss of water supply as the result of drought conditions could reduce or eliminate water supply allocated for the conservation strategy.

The study area lies in an area with several major and minor faults; moreover, the study area is susceptible to significant wildfires in the dry months of June–October. These natural events have the ability to damage the Reserve System and certain structural elements of the conservation strategy.

Fire would remove vegetation, potentially including riparian vegetation, and, in the event of significant precipitation following the fire, could compromise water quality in streams and reservoirs by increasing turbidity, increasing suspended sediment loads, and introducing high volumes of organic carbon into watersheds. This may affect the suitability of habitat for native fish and covered amphibians. Additionally, loss of riparian vegetation can lead to loss of habitat for terrestrial species found in riparian habitats. See Chapter 10 for additional discussion of foreseeable and unforeseen circumstances addressed by this Plan.

### 5.3.7 Wetland and Pond Conservation and Management

#### Biological Goals and Objectives

During Plan implementation, the Implementing Entity will work toward the goal of maintaining and enhancing functional wetland and pond habitats to benefit covered and other native species. The Implementing Entity will accomplish this by protecting lands with predominantly grassland, oak woodland, and conifer woodland land cover and that contain ponds or wetlands through fee title purchase or conservation easement. The Reserve System will contain the full range of pond and seasonal and perennial wetland communities that occur within the study area, and those ponds and wetlands and their adjacent uplands will be managed as part of the Reserve System. In addition, all Reserve System lands will be enhanced. Freshwater perennial and seasonal wetlands and ponds enhancement includes increasing native vegetative cover, biomass, and structural diversity in and around the margins of these aquatic habitats.

Wetland and pond conservation and management will benefit 8 covered species. Wildlife use includes movement, foraging, breeding, and year-round habitat. Seasonal wetlands may provide suitable habitat for one covered plant, fragrant fritillary (see Section 5.4.14 *Fragrant Fritillary*). Bay checkerspot butterfly may use wetland and pond habitat for movement as they move within and between serpentine grassland habitat patches (see Section 5.4.1 *Bay Checkerspot Butterfly*). California tiger salamander uses wetland and pond habitats for breeding and foraging (see Section 5.4.2 *California Tiger Salamander*). California red-legged frog uses perennial wetlands as year-round habitat and seasonal wetlands and ponds for breeding and foraging (see Section 5.4.3 *California Red-legged Frog*). Western pond turtle uses perennial wetlands and ponds as year-round habitat and seasonal wetlands as foraging habitat (see Section 5.4.5 *Western Pond Turtle*). Western burrowing owl uses season wetlands as movement habitat (see Section 5.4.6 *Western Burrowing Owl*). Tricolored blackbird uses wetlands and ponds as foraging and breeding habitat

(see Section 5.4.8 *Tricolored Blackbird*). The acquisition, enhancement, restoration, and creation conservation actions identified in the following sections are intended to benefit these species and the natural communities.

The preservation and restoration/creation mitigation ratios for impacts to ponds and wetlands are additive (**Tables 5-13 and 5-21**). For example, for every one acre of perennial wetland impacted, 2 acres must be preserved and enhanced (2:1) and 1 acre must be restored (1:1). This results in a mitigation ratio of 3:1 for all perennial wetland impacts. For every 1 acre of seasonal wetlands impacted, 2 acres must be preserved and enhanced (2:1) and 2 acres must be restored (2:1). This results in a mitigation ratio of 4:1 for all impacts to seasonal wetlands. For every 1 acre of pond impacted, 2 acres must be preserved and enhanced (2:1) and 1 acre must be created (1:1). This results in a mitigation ratio of 3:1 for all pond impacts.

Regardless of the level of impacts, a minimum of 10 acres of perennial wetlands, 5 acres of seasonal wetlands, and 50 acres of ponds must be preserved to contribute to recovery. As explained above, minimum preservation requirement can be met by the impact ratios. For example, if 5 acres of perennial wetlands are impacted, and 10 acres are preserved, this will fulfill the minimum preservation requirement for perennial wetlands.

There are also minimum wetland restoration and pond creation requirements that must occur regardless of the level of impact (**Table 5-13**). In addition to the mitigation ratios, a total of 20 acres of perennial wetlands must be restored and 20 acres of ponds must be created to contribute to recovery.

Uplands between ponds and wetlands will be similarly managed to attain regional connectivity for native species (See Sections 5.3.3 *Grassland Conservation and Management* and 5.3.4 *Chaparral and Northern Coastal Scrub Conservation and Management*, above). Ultimately the result will be a wetland/pond/upland habitat matrix that will support multiple life stages of covered and other native species (LAND-G2, LAND-OC1, LAND-OC2, LAND-OC3, LAND-OC4, LAND-OC5). Ponds and wetlands will be further enhanced by eradicating or reducing exotic species (e.g., nonnative fish, bullfrogs, nonnative plants) that are detrimental to covered and other native pond and wetland species. These and other specific management prescriptions are discussed below.

## Acquisition, Enhancement, Restoration, and Creation

The Implementing Entity will acquire an estimated 184 acres of wetlands and ponds within the Reserve System (**Table 5-12**). The Implementing Entity will enhance all Reserve System lands. The Implementing Entity will also restore or create an estimated 147 acres of wetlands and ponds (**Tables 5-12 and 5-13**).

## Wetland and Pond Acquisition

The amount of wetlands and ponds protected will be driven, in part, by the level of impact. Wetland and pond impacts require a 2:1 preservation ratio. During Plan implementation, the Implementing Entity will protect an estimated 50 acres of perennial wetlands (coastal and valley freshwater marsh; LAND-WP1a, LAND-WP1b), 30 acres of seasonal wetlands (LAND-WP2a, LAND-WP2b), and 104 acres of ponds through fee title purchase or conservation easement and manage them as part of the Reserve System (**Table 5-12**).

Regardless of the level of impact, a minimum of 50 acres of ponds must be protected to protect habitat for covered species (tricolored blackbird, California red-legged frog, California tiger salamander, and western pond turtle; **Table 5-12**). Ponds will be protected on both sides of the Santa Clara Valley to ensure that representative populations of pond-associated covered species are included in the Reserve System (LAND-G2, LAND-OC1, LAND-OC2, LAND-OC3, LAND-OC4, LAND-OC5). The land acquisition strategy focuses on land acquisition in areas with higher concentrations of ponds; these areas include, but are not limited to, the area between Alum Rock Park and Joseph D. Grant County Park, the area between Cañada de Oro Preserve and Chesbro Reservoir, and the area south of Henry W. Coe State Park along the Cañada de los Osos. When possible, pond protection will be pursued within designated critical habitat for California tiger salamander and California red-legged frog. Joseph Grant County Park has existing open space that will be added to the Reserve System that includes substantial ponds (**Table 5-5**).

In addition to the pond acquisition described above, a minimum of 10 acres of perennial wetland and 5 acres of seasonal wetland will be acquired, regardless of the level of impact (**Table 5-13**). These land cover types are rare in the study area but occur mostly on the floor of the Santa Clara Valley or in the nearby foothills.

All wetland and pond protection will occur by Year 45 according to the Stay-Ahead provision described in Chapter 8, Section 8.6.1 *Stay-Ahead Provision*. This provision requires that stream woodland and scrub protection requirements be met prior to impacts occurring to these land cover types, with a 10% allowable deviation.

## Wetland and Pond Enhancement

The Implementing Entity will enhance all Reserve System lands. All estimated 184 acres of wetlands and ponds acquired for the Reserve System (**Table 5-12**) will be enhanced to benefit covered and other native species. In addition, the estimated 147 acres of wetlands and ponds restored and created will be maintained once they meet their success criteria, and enhanced, as indicated by targeted studies and informed by the monitoring and adaptive management program. Wetland and pond enhancement will begin immediately after reserve unit management plans are completed or updated for each reserve unit.

Habitat enhancement is the improvement of an existing terrestrial vegetation community or aquatic habitat. Within the Reserve System, degraded ponds and wetlands will be improved to increase overall ecological functions and values (e.g., native species richness and diversity, wildlife habitat function) and to enhance the ability of these habitats to support existing and new populations of covered species. Wetland and pond enhancement measures will be designed for specific wetland or pond types (e.g., hydrogeomorphic context, surrounding natural community) and, in some cases, for specific sites. As described below, the success of various techniques depends on the wetland or pond type and the site conditions under which they are applied. Wetlands or ponds that are highly degraded may require more intensive management. Wetlands or ponds already in good condition (e.g., that support healthy populations of covered species) may require little or no enhancement measures.

## Perennial and Seasonal Wetland Restoration

Wetland impacts require a 1:1 restoration ratio for perennial wetlands and 2:1 restoration ratio for seasonal wetlands. The Implementing Entity will restore freshwater perennial and seasonal wetlands in-kind within the Reserve System according to the level of impact to these land cover types. If all expected impacts occur, this will result in an estimated total restoration of 25 acres of freshwater marsh and 30 acres of seasonal wetlands, per the required mitigation ratio (**Table 5-12**). In addition to the mitigation ratios, the Implementing Entity will restore at least 20 acres of perennial wetlands within the Reserve System to contribute to recovery (POND-6) (**Table 5-13**). This wetland restoration will occur regardless of the level of impacts and will contribute to the recovery of covered wetland species.

Habitat restoration is the establishment of a vegetation community or aquatic habitat in an area that historically supported it, but no longer does because of the loss of one or more required ecological factors or as a result of past disturbance. Wetland restoration will be carried out in areas that will increase available habitat and enhance connectivity between existing ponds and wetlands within the Reserve System. Potential wetland restoration and pond creation sites will be selected within the same watershed as the expected wetland impacts. This prioritization will ensure that wetland mitigation occurs close to the impact area and preserves and enhances watershed functions. Restoration will occur on suitable soils and in areas where wetlands historically occurred and have since been drained or severely degraded. Additional site selection guidelines are provided below under *Guidelines for Selecting Restoration or Creation Sites*. Restoration may include recreating the historic topography of the site and planting native freshwater emergent and aquatic plants. Seasonal wetlands may be restored along floodplain benches of intermittent streams or in grassland swales. Additional guidelines for restoring wetlands is provided below under *Restoration and Creation Principles and Techniques*.

All restoration of these land cover types will be completed by Year 40 (i.e., construction will be completed) and according to the Stay-Ahead provision described in Chapter 8, Section 8.6.1 *Stay-Ahead Provision*. All required

restoration of perennial or seasonal wetlands must be initiated (ground breaking) prior to impacts occurring to these land cover types. In addition, the Implementing Entity will complete restoration of perennial wetland to contribute to species recovery according to the deadlines in **Table 5-14** (Years 15, 30, and 40).

## Pond Creation

Pond impacts require a 1:1 creation ratio (**Table 5-12**). The Implementing Entity will create ponds lost to covered activities, in-kind, within the Reserve System. The total allowable impact on pond land cover during the permit term is 52 acres. In addition to the creation ratio, the Implementing Entity will create a minimum of 20 acres of ponds to contribute to recovery (POND-9) (**Table 5-13**). Pond creation to contribute to recovery is in addition to the mitigation ratio and will occur regardless of the level of impacts on ponds to contribute to the recovery of covered pond species (California red-legged frog, California tiger salamander, western pond turtle). Consequently, an estimated 72 acres of ponds will be created and managed as part of the Reserve System to offset these impacts and contribute to species recovery (52 acres + 20 acres = 72 acres). Pond creation will increase available habitat and enhance connectivity among existing ponds and wetlands within the Reserve System (**Figure 3-13**). Pond creation will only occur off-stream to avoid additional impacts to streams. Additional site selection guidelines are provided below under *Guidelines for Selecting Restoration or Creation Sites*.

The Habitat Plan assumes that ponds will be created (i.e., development of the pond land cover type in an area that did not previously support it). However, if an existing or historic pond were degraded to the point that it lacks certain ecological functions that are essential to support covered species (e.g., a pond is filled with sediment and no longer holds water), then restoration of a pond may be counted toward the Plan's creation requirements for ponds. Whether a pond restoration may be counted toward pond creation requirements will be determined by the Implementing Entity and Wildlife Agencies during the Wildlife Agency review of the proposed restoration design.

New ponds will be sited to improve habitat connectivity for California red-legged frog, California tiger salamander, and western pond turtle. The Implementing Entity will identify gaps between occupied ponds that are greater than typical dispersal distances (e.g., California tiger salamander may travel up to 1.3 miles from a breeding site) but short enough such that the creation of a pond may bridge the gap.

Where feasible, created ponds will rely on passive management (e.g., they will dry on their own periodically) to minimize the need for artificial draining. However, all created ponds will include a mechanism for draining, to control bullfrogs and other invasive nonnative wildlife species (described in Section 5.3.2 *Landscape Conservation and Management*). Pond creation to mitigate for impacts will be accomplished by creating ponds of approximately the same size as those lost. Pond creation to contribute to recovery will be

accomplished by creating ponds with an approximate average size of 0.5 acre, although small isolated ponds may be created that are only a few meters across because such ponds may provide habitat for California red-legged frogs and California tiger salamander, but may not be attractive to bullfrogs (U.S. Fish and Wildlife Service 2002). Native emergent and aquatic vegetation will be planted in ponds to provide suitable breeding habitat for covered species. Additional guidelines for restoring wetlands is provided below under *Restoration and Creation Principles and Techniques*.

Construction of all ponds will be completed by Year 40 and according to the Stay-Ahead provision described in Chapter 8, Section 8.6.1 *Stay-Ahead Provision*. All required pond creation must be initiated (ground breaking) prior to impacts. In addition, the Implementing Entity will complete pond creation to contribute to species recovery according to the deadlines in **Table 5-14** (Years 15, 30, and 40).

## Management Techniques and Tools

### Wetland Restoration and Pond Creation

All wetlands and ponds restored or created will be designed to support covered aquatic or amphibian species when physical and biological conditions allow. Biologically appropriate management techniques will be determined on a site-specific basis.

#### Guidelines for Selecting Restoration or Creation Sites

Potential restoration sites will be identified and selected on the basis of their physical processes and hydrologic, geomorphic, and soil conditions to ensure that successful restoration can occur and be self-sustaining. Such an approach increases the likelihood of successful restoration and reduces long-term management and maintenance costs.

Restoration sites will be selected within the same watershed as the expected wetland impacts. This prioritization will ensure that wetland mitigation occurs close to the impact area and preserves and enhances watershed functions. Restoration of perennial and seasonal wetlands will occur on suitable soils and in areas where perennial wetlands historically occurred and have since been drained or severely degraded, if appropriate hydrologic conditions still exist (San Francisco Estuary Institute 2006, 2007).

Restoration sites will also be selected on the basis of their ability to support covered species, support implementation of species-specific conservation actions, and meet species-specific biological goals and objectives. For example, sites designed to support tricolored blackbird will be located a sufficient distance away from black-crowned night-heron rookeries to minimize predation on tricolored blackbirds. Sites designed to support breeding habitat for covered amphibians must have adequate nearby upland habitat. Restoration and creation sites for wetlands and ponds must meet minimum distances from urban

development to receive credit under this Plan (**Table 5-15**). Created ponds will be sited away from busy roads to reduce the likelihood of mortality during periods when frogs, turtles, and salamanders move between ponds and uplands. In accordance with the California red-legged frog Recovery Plan, ponds created to provide red-legged frog habitat shall incorporate the *Guidelines for Voluntary Pond Management for the Benefit of the California Red-legged Frog* or the best available science during Plan implementation. This currently includes the following siting and design criteria.

- Evaluate the distance from known occurrences California red-legged frog to increase the likelihood of species dispersal to the created habitat.
- Place ponds at least one kilometer (0.6 miles) from known occurrences of bullfrogs.

### **Restoration and Creation Principles and Techniques**

Wetland restoration or pond creation will be accomplished using the techniques outlined in this section.

#### **Coastal and Valley Freshwater Marsh Restoration (Perennial Wetlands)**

The Implementing Entity will restore perennial freshwater wetlands at a ratio of 1:1 to replace wetlands lost to covered activities (estimated to be 25 acres of compensation) and restore an additional 20 acres of perennial freshwater wetlands to contribute to species recovery (**Table 5-12**).

One of the key principles of successful restoration is the presence of the processes that create and maintain wetlands (Middleton 1999; Keddy 2000; Mitsch and Gosselink 1993). The most important processes are related to the availability of water and appropriate hydrology to create and maintain hydric soils and plants. Therefore, restoration of perennial wetlands will occur on sites with appropriate hydrology. This may include areas where perennial wetlands historically occurred and have since been drained or severely degraded. Additionally, there may be sites that are currently appropriate for perennial wetlands that did not historically support them, because of changing land uses and altered hydrologic flows. It is imperative that perennial wetlands restoration sites be located directly adjacent to or connected to a source of permanent water.

Restoration will occur on suitable soils and may include creating wetland topography. Specifically, this might include site grading and creation of depressions to hold water. The choice of plant species for perennial wetland restoration sites will be based on a palette of native wetland plants including freshwater emergent and aquatic species. The palette will be developed during the implementation process. Ideally, the plants will be grown from soil, seed, or plant stock from local wetland sites. In addition, vegetation is expected to evolve after the original planting such that “volunteer” species may move into the wetland over time. In some cases, this can include nonnative invasive species that are not desirable within the Reserve System. Therefore, restoration plans will include plans for management of nonnative invasions. Additional issues that will be addressed in wetland design include preventing fish from becoming trapped in the ponds if the hydrology source is from a perennial waterbody that supports fish (e.g., by the use of fish screens or other appropriate devices).

Examples of wetland restoration projects in the study area that will be consulted for lessons learned (e.g., the Coyote Creek wetland restoration project (SCVWD), which occurs off-channel on Coyote Creek adjacent to U.S. 101).

### **Seasonal Wetland Restoration**

The Implementing Entity will restore seasonal wetlands at a ratio of 2:1 to replace all functions and values lost to covered activities (estimated to be 30 acres<sup>27</sup> of compensation; **Table 5-12**).

As with perennial wetlands, the most important principle for successful restoration and maintenance of seasonal wetlands is appropriate hydrology. However, for seasonal wetlands, the source of water should be available during the winter rainy season and not available during the dry summer months. Therefore, seasonal wetland restoration will include appropriate hydrologic sources and processes to support the seasonality of the wetland feature. This may occur on sites that supported seasonal wetlands historically, if appropriate hydrologic processes are still in place or can be restored. It may also include sites that have been altered by recent land uses and now support suitable hydrology.

The soils for seasonal wetlands generally will have water-holding capacity. This usually means some amount of clay content. Soils will be examined and tested before seasonal wetlands are sited. The plant palette for seasonal wetlands, as with perennial wetlands, will be developed during the restoration planning process. The choice of plant species for seasonal wetland restoration sites will be based on a palette of native seasonal wetland plants. Plants used for restoration will ideally be grown from local plant sources (soil, seed, and plant stock).

Because plant species composition, along with hydrologic processes, may change after the original planting, “volunteer” species may move into the wetland over time. This is to be expected because wetlands are dynamic systems. In some cases, such changes may include nonnative invasive species that are not desirable within the Reserve System. Therefore, restoration plans will include plans for management of nonnative invasions.

### **Pond Creation**

Ponds will be created to support breeding habitat for California red-legged frog, California tiger salamander, western pond turtle, tricolored blackbird, or a combination of these species. Pond depth will be sufficient to provide suitable breeding habitat for red-legged frogs or tiger salamanders and to preclude dense growth of emergent aquatic vegetation. Pond size will vary depending on the availability of water and site and watershed conditions. Ponds will be created to supplement the existing important network of stock ponds that exist in the study area, particularly in the Diablo Range where livestock grazing is more common. Ponds will not be created in streams to avoid stream impacts, preclude fish-

<sup>27</sup> Actual acreage of seasonal wetland compensation is expected to be less than 30 acres because seasonal wetland impacts and compensation will be tracked based on the wetland delineation submitted to, and verified by, the Local jurisdictions or Implementing Entity (See Chapter 6, Section 6.8.4). This land cover type was mapped at a regional scale using wetland complexes rather than site-specific data.

stranding, and avoid creating predator sinks. Ponds will be created so that they can be drained if necessary to control bullfrogs and other nonnative invasive animals.

Sediment inputs to ponds must be controlled to maintain the pond in the long term and minimize the need for periodic dredging. Upstream in-channel measures and small forebays can be used to reduce sediment delivery to the created ponds.

Ponds will be designed so that they either do not retain water long enough to support establishment of bullfrogs, nonnative fish, or other predators of California red-legged frog and California tiger salamander, or can be artificially drained to deter such establishment. At the same time, they will be designed to remain ponded for sufficient duration to support successful breeding of California red-legged frog and/or California tiger salamander. A deep-water escape portion, deeper than 1 meter (3 feet) and shallow, tadpole- and juvenile rearing portion to provide high quality breeding habitat for California red-legged frog shall be included (U.S. Fish and Wildlife Service 2002). Native emergent and aquatic vegetation will be planted in ponds to provide suitable breeding habitat for these covered species.

## **Wetland and Pond Enhancement**

All wetlands and ponds within in the Reserve System will be enhanced. The Implementing Entity will use the management techniques described below to enhance Reserve System wetlands and ponds.

### **Vegetation Management**

Vegetation management is a critical component of optimizing the habitat function of ponds and wetlands for covered species. Consequently, wetland and pond vegetation will be managed depending on the site-specific conditions of individual wetlands and ponds, and will largely depend on the individual species or group of species targeted for enhancement (or removal in the case of invasive nonnative species). Vegetation management will involve several techniques, often used in concert, to achieve the species composition and habitat structure necessary to benefit covered and other native species.

Some existing ponds or wetlands and all created ponds or restored wetlands will be seeded with native vegetation appropriate for the surrounding natural communities for replacement of lost ecological services and function. Planting of emergent vegetation (POND-3) such as bulrushes or willows in ponds that lack vegetation can improve breeding habitat and cover for California red-legged frog, western pond turtle, and California tiger salamander in the deepwater portions (i.e., greater than 1 meter deep); however, they should be kept clear of the shallow portions as tadpole-rearing portions should remain unshaded and shallow for California red-legged frog breeding habitat (U.S. Fish and Wildlife Service 2002). Further, tall emergent vegetation, such as bulrushes, can provide roost and nest sites for tricolored blackbirds where the wetlands or ponds are located near foraging habitat. Wetlands or ponds with adjacent grasslands or oak

woodlands will benefit from selective seeding of native forbs or grasses in the uplands surrounding the pond/wetland fringe (GRASS-4).

Vegetation may have to be removed from ponds where little open water remains to improve conditions for western pond turtle, California tiger salamander, and California red-legged frog. Vegetation removal can be accomplished through grazing (see below), selective herbicide application using label-approved application technique and in calm winds, or mechanical means (LM-11, LM-14). Where feasible, prescribed burns will be used to control nonnative vegetation around ponds and wetlands and within pond or wetland complexes (GRASS-2). Any herbicide application conducted in ponds or wetlands must use products that have been approved for aquatic communities. Mechanical removal of vegetation would occur after the breeding season for wetland- and pond-dependent wildlife, including nesting migratory birds, to minimize impacts. If surveys identify California red-legged frog presence at a pond requiring vegetation management, such activities would be restricted to between August 30<sup>th</sup> and October 15<sup>th</sup>. In cases where covered species are dependent on nonnative vegetation (e.g., tricolored blackbirds nesting in Himalayan blackberry) the removal of nonnative vegetation will be undertaken in phases over a 3 to 4-year period and replaced with the appropriate native vegetation.

Overgrazing by cattle and rooting by feral pigs can cause trampling of vegetation, soil compaction, development of “cow contours,” and bank destabilization. Fencing ponds and wetlands (POND-1) has been shown to be a rapid, successful, and cost-effective method of enhancing some wetlands. After fencing, vegetation cover and wetland species diversity can increase substantially in stock ponds and other permanent or near-permanent freshwater wetlands that have been degraded by cattle grazing (Contra Costa Water District 2002). In this Plan, fencing locations and specifications will depend on several factors, including site-specific conditions and the biological objectives that are being addressed. Fencing wetlands may not be appropriate in locations where retaining open water for species such as western pond turtle and California tiger salamander is an objective. In such cases, fencing half of a pond or wetland (split fencing) may accommodate the needs of multiple covered species (U.S. Fish and Wildlife Service 2002).

Livestock grazing (LM-11) will be introduced or continued at some wetlands and ponds to eliminate or reduce cover of exotic plants and to maintain ponds by preventing excessive plant growth when such a technique is consistent with maintaining values for covered species. Grazing rotation and fencing can also reduce the erosive impacts described above. Ford et al. (2012) provide details about pond habitat quality for the special-status California red-legged frog and California tiger salamander. The period of a pond’s inundation is critical to habitat value as well as the livestock operation that is associated with the pond’s establishment and maintenance. Ponds that draw down in the late spring or early summer can become unsuitable for livestock use due to lack of water and dangerous muddy banks.

To support successful reproduction of these special-status amphibians, their pond or stream habitats must remain inundated long enough to support successful

metamorphosis, which for California red-legged frog is December through April, and for California tiger salamander through May (U.S. Fish and Wildlife Service 2010). The California red-legged frog need ponds with a mix of open surface water and vegetated cover in the pond and at the edges. Emergent and edge vegetation provides cover for adult frogs from native and non-native predators, which is especially important if the non-native predators are not controlled. Emergent or submerged vegetation is also important in providing structure for attachment of frog eggs. The California tiger salamander typically use ponds free of emergent vegetation. Aquatic vegetation can be compatible, especially submerged vegetation, but salamander breeding appears to be rare with moderate levels of emergent vegetation. Allowing limited livestock access to a pond will help maintain its usefulness as habitat for covered species by preventing excessive plant growth that can lead to rapid sedimentation of ponds (U.S. Fish and Wildlife Service 2002). Seasonally limited grazing can be effective at reducing competition for nonnative plant species in seasonal wetlands (Marty 2005).

In addition to managing grazing of ponds and wetlands, grazing of surrounding grassland will be managed to maintain optimal habitat conditions. The use of livestock grazing within the Reserve System is discussed above (Section 5.3.3 *Grassland Conservation and Management*).

### **Water and Other Management**

It is assumed that many ponds in the study area are in disrepair. Repairs could be made to improve water retention in ponds created as stock ponds that are not retaining water due to leaks and, as a result, not functioning properly as habitat for covered species. Additionally, pond capacity and water duration can be increased (e.g., by raising spillway elevations) to support covered species populations.

In order to retain the habitat quality of ponds and wetlands over time, occasional sediment removal may be needed to address the buildup of sediment that results from adjacent land use or upstream factors (POND-4). Dredging will be conducted during the non-breeding periods of covered and other native species.

The Implementing Entity will also work with private landowners who own key ponds to secure funding to improve and maintain their ponds as habitat for covered species (e.g., tricolored blackbird, California tiger salamander, California red-legged frog, or western pond turtle). The Implementing Entity will help landowners apply for existing grants to enhance pond and freshwater marsh habitat on their land (e.g., North American Wetlands Conservation Act Small Grants Program [USFWS], or Environmental Quality Incentives Program of the Farm Bill [USDA Natural Resources Conservation Service]) (POND-11, POND-14). The Implementing Entity will work closely with existing organizations that have strong relationships with private landowners such as the Natural Resources Conservation Service, the local Resource Conservation District, and the California Cattlemen's Association. A program could be developed in the study area modeled after the successful Alameda County Conservation Partnership in Alameda County. This program provides technical

assistance, funding, and permit streamlining to private landowners wishing to maintain and enhance stock ponds to benefit endangered species.

Coarse woody debris or anchored basking platforms will be installed in ponds to improve habitat for western pond turtles (Hays et al. 1999) (POND-2). This modification will increase the habitat value in locations with existing western pond turtles and in newly created ponds where it is hoped that new pond turtle populations will establish. These structures may also enhance habitat for native amphibian species.

### **Nonnative Wildlife Management**

The Implementing Entity will work to reduce and, where possible, eradicate nonnative exotic species that adversely affect native pond and wetland species. These efforts will include prescribed methods for removal of bullfrogs, mosquitofish, and nonnative predatory fish from stock ponds and wetlands within the Reserve System. Further, the Implementing Entity will reduce the overall population of feral pigs within the permit area to reduce degradation of pond and wetland habitats. In some cases monitoring exotic species can be best accomplished by documenting the impact of those species on natural landscapes. It would be difficult to census the number of feral pigs within the Reserve System without an extensive effort. However, rooting disturbance can be monitored. The pig population will be controlled to levels that do not preclude the Implementing Entity's ability to successfully reach the Plan's goals and objectives.

### **Private Landowner Education**

The Implementing Entity will establish a landowner education program to provide technical and financial assistance to maintain and enhance ponds and other wetlands on private lands. Wetland enhancement may include pond stabilization, nonnative species control, pond or wetland expansion, or water management structures. Details are found under *Public Education and Outreach* in Section 5.3.2 *Landscape Conservation and Management* above. A similar, successful program operates in Alameda County in similar habitat under the auspices of the Alameda County Resource Conservation District and the USDA National Resource Conservation Service.

## **Threats and Uncertainties**

In general it is anticipated that a greater acreage of ponds than of wetlands will be protected through fee title acquisition or conservation easement because wetland protection and restoration opportunities are likely to be rare on the Santa Clara Valley floor, where most of the study area's wetlands are found. Although pond habitat is not a complete surrogate for wetland habitat in terms of ecological services and function, it does support the necessary life history stages for all the covered pond species in this Plan. However, ponds will not be used as out-of-kind mitigation for impacts to wetlands.

When creating or restoring aquatic habitat, the success of the habitat transformation is always dependent upon adequate water supplies during critical

life stages of covered species. During periods of drought, pond and wetland habitat may dry prior to the completion of covered species' aquatic life stages (i.e., breeding ponds for California tiger salamander and/or California red legged frogs may dry prior to metamorphosis). While ponds and wetlands will be created or restored to periodically dry on their own, periods of extended drought are inevitable and may diminish the quality of the aquatic habitat in some years.

### **Limitations of Restoration**

Restoring or enhancing hydrologic function to the immediate watersheds of wetlands and ponds will enhance habitat function of these features. Upstream factors that may be contributing to the decline of seasonal wetlands in the study area include hydrologic changes that lead to channel incision, changes in channel runoff, hydrologic disconnection of channel and floodplain, lowering of groundwater, and reduction of soil moisture in riparian areas. A variety of methods/approaches are available to arrest channel incision. For example, grazing management and fencing (see above) can be used to curtail negative hydrologic effects. Check dams have been shown to be effective at arresting channel erosion in seasonal wetlands in the Los Vaqueros Watershed in Contra Costa County within 6 months of dam installation (Jones & Stokes Associates 1992). Over time, such small dams may also increase the recharge of the local aquifer, raising the water table and increasing soil moisture levels near the surface. This effect could, in turn, increase the cover and extent of seasonal wetland vegetation along stream channels.

### **Mosquito Abatement**

Enhancement of pond and wetland habitats must be balanced with the need to minimize mosquito production. Encouraging adequate populations of mosquito predators, such as native frogs, swallows, and bats, offers an approach to mosquito control that is compatible with management for covered species. Wetlands will be designed to reduce mosquito production by minimizing suitable habitat for mosquitoes (primarily *Culex tarsalis*) and other human disease vectors, particularly between mid-July and late September or October when mosquito productivity is highest. Any mosquito control activities to be performed on Reserve System land will be addressed in the reserve unit management plan in consultation with the Santa Clara County Vector Control District. The reserve unit management plan will detail the nature of mosquito control activities and explain specific measures implemented to avoid and minimize impacts to covered species consistent with the Habitat Plan.

## **5.4 Benefits of and Additional Conservation Actions for Covered Species**

Most species-specific conservation is accomplished by protecting, restoring, and managing natural communities as described above. For 17 of the covered species, a GIS-based approach was used to estimate the amount of modeled habitat to be protected within the Reserve System. The species account for most species contains a section called *Modeled Habitat Distribution in Study Area*

detailing the parameters used to identify modeled species habitat (see **Appendix D**). Modeled species habitat was overlaid with the proposed Reserve System (see Section 5.2.3 *Reserve System*). The amount of modeled species habitat protected within the proposed Reserve System is identified for each covered species below. In addition, the number and size (if known) of covered plant occurrences protected within the proposed Reserve System are also discussed. Some species-specific actions were also included within these natural community management sections. The following section describes the biological goals and objectives for covered species and summarizes the benefits of the conservation actions for each species. When applicable, conservation actions in this Plan are related to federal critical habitat designations and federal Recovery Plan actions.

As discussed in Chapter 1, California State Parks lands are excluded from the permit area. Because of this exclusion, all of the land cover-related analyses in the Plan are based on the study area less State Parks lands unless otherwise noted. The size of the study area less State Parks lands is 460,205 acres.

## 5.4.1 Bay Checkerspot Butterfly

### Biological Goals and Objectives

The Implementing Entity will improve the viability of existing Bay checkerspot butterfly populations, increase the total number of populations, and expand the geographic distribution of the species to ensure its long-term persistence in the study area. This will be accomplished by protecting most serpentine grasslands within the study area to ensure protection of the ranges of slopes, aspects, and microhabitats important to the species. Acquisition, enhancement, and restoration/creation of natural communities adjacent to serpentine grasslands, including grasslands (see Section 5.3.3 *Grassland Conservation and Management*), chaparral and coastal scrub (see Section 5.3.4 *Chaparral and Northern Coastal Scrub Conservation and Management*), oak woodlands (see Section 5.3.5 *Oak and Conifer Woodland Conservation and Management*), riparian forest and scrub (see Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management*), and wetlands and ponds (see Section 5.3.7 *Wetland and Pond Conservation and Management*) are expected to benefit Bay checkerspot butterfly through the conservation and management of movement habitat.

Additionally, the Implementing Entity will improve management in degraded serpentine grasslands in the Reserve System to enhance populations of the larval host plants and adult nectar sources to benefit Bay checkerspot butterfly populations.

## Habitat Acquisition and Enhancement

The 1998 serpentine soils species Recovery Plan prioritizes 8,674 acres of then-unprotected habitat (i.e., not “fully or partially protected park lands”) within specific portions of the study area that “are considered essential to the recovery” of the species (U.S. Fish and Wildlife Service 1998a). The 1998 Recovery Plan also states that there are “other current or historic localities or suitable habitat areas, generally larger than” 2.5 acres that are also “essential to the recovery” of the species; however, these areas were not specifically identified (U.S. Fish and Wildlife Service 1998a). These prioritizations for protection were based on habitat mapping that occurred prior to the development of the Habitat Plan. The mapping of Bay checkerspot habitat for the Plan resulted in a new more accurate estimate of unprotected habitat in the study area of a total of 7,285 acres (total habitat modeled less habitat in Type 1 Open Space) (**Table 5-7**; see Chapter 3 and the species account in **Appendix D** for details on the habitat mapping).

Habitat models developed for this Plan estimated 8,621 acres of Bay checkerspot butterfly modeled habitat within the study area; this does not include all serpentine bunchgrass lands within the study area. Areas mapped as serpentine rock outcrop in this Plan are excluded from modeled Bay checkerspot butterfly habitat because these land cover types are assumed to be barren and thus not considered suitable habitat for the species. 2,921 acres (34%) of modeled habitat are located on Type 1, 2, or 3 open space with 1,336 acres (15%) permanently protected as Type 1 open space. The Plan will acquire 3,800 acres of lands modeled as habitat for the Reserve System and add 754 acres of modeled habitat from existing open space to the Reserve System (**Table 5-17**). With the total Reserve System lands (4,554 acres = 3,800 acres + 754 acres) added to land already protected as Type 1 open space (1,336 acres), a total of 5,890 acres of Bay checkerspot butterfly modeled habitat would be protected, or 68% of total modeled habitat in the study area.

The Implementing Entity will protect at least 4,000 acres of serpentine bunchgrass grassland (**Tables 5-19**) (3,800 acres of which includes modeled habitat for Bay checkerspot butterfly) through fee title acquisition or the acquisition of conservation easements. The conservation strategy for the Bay checkerspot butterfly, in combination with existing Type 1 open space, protects 70% of the core habitat on Coyote Ridge, extending from the north end of Coyote Ridge south to Anderson Dam (including the Pigeon Point unit). This acquisition will include the core habitats along the ridge tops, which have historically (since 1984) supported the densest populations of Bay checkerspot butterfly. Of the 4,000 acres of serpentine grassland to be preserved, the proposal is to acquire a minimum of 2,900 acres located on Coyote Ridge (LAND-L5). Extensive land acquisition will occur in all four of the core habitat areas as defined in the Recovery Plan for the species (U.S. Fish and Wildlife Service 1998a): Kirby, Metcalf, San Felipe, and Silver Creek Hills (see **Table 5-7** for a cross-walk of site names between this Plan and the Recovery Plan). The primary focus of land acquisition will be Coyote Ridge. The Plan also protects secondary sites deemed essential for the recovery of the species, including:

- The Santa Teresa Hills, a “potential core area” and “stepping stone” in the Recovery Plan. Approximately 877 acres (53%) of Santa Teresa County Park are proposed for incorporation into the Reserve System and would be managed to improve habitat for this species; most of this area supports serpentine bunchgrass grassland (over 670 acres). Once enhanced through livestock grazing, the improved habitat is expected to attract Bay checkerspot butterfly back to this part to re-establish a lost population (**Table 5-5**)<sup>28</sup>.
- Tulare Hill (deemed an important corridor for this species to connect populations in the Diablo Range with populations in the Santa Cruz Mountains),
- West hills of the Santa Clara Valley: 75% of the currently unprotected portions of Hale/Falcon Crest, Kalana Avenue, and Canada Garcia sites.

Land acquisition will protect occupied and potential habitat for the species, and protect critical linkages for the species. Protection of landscape linkages 6 and 8 (**Table 5-9** and **Figure 5-9**) will directly benefit Bay checkerspot butterfly. Protection of the linkage between the Silver Creek and Metcalf populations (LAND-9, LAND-L4) and the linkage between Coyote Ridge and Tulare Hill is critical for the species and will be necessary to meet the biological goals and objectives for this species.

The Implementing Entity will acquire and manage enough habitat to ensure occupancy by Bay checkerspot butterfly of each of the four core habitat units identified in the 1998 Serpentine Recovery Plan (Kirby, Metcalf, San Felipe, and Silver Creek Hills). Occupancy in these four core habitat units will be demonstrated at least four out of every 10 consecutive years of the permit term. The Implementing Entity will also acquire and manage land to ensure occupancy of at least three of the six (50%) satellite habitat units identified in the 1998 serpentine Recovery Plan (**Table 5-7**) by Year 45 (see Section 5.3.1 *Land Acquisition and Restoration Actions* subheading *Acquisition of Occupied Habitat for Select Wildlife Species*).

Successful implementation of the Plan will result in the protection of a portion of all Bay checkerspot critical habitat units (**Table 5-21** and **Figure 4-3**) (U.S. Fish and Wildlife Service 2008). In most cases, more than 48% of each of the 9 critical habitat units will be protected.<sup>29</sup> Habitat protection will occur on Coyote Ridge (northwest and southeast of Motorcycle County Park; Units 5 and 13), Tulare Hill (Unit 6), Santa Teresa Hills (Unit 7), west of Calero Reservoir (Unit 8), the Kalanas and Hale/Falcon Crest (Units 9a and 10), and Bear Ranch (Unit 11) (LAND-G3). These acquisitions will permanently protect important linkages between core and satellite habitat units and guarantee standardized management and monitoring, something that has not occurred in the past. Protection of sites will be prioritized according to threat, occupancy history and

<sup>28</sup> Estimates of County Park lands incorporated into the Reserve System are approximations. Final amounts will be determined during implementation when conservation easements are established and more detailed mapping is conducted.

<sup>29</sup> Critical habitat units 9a and 9b are referred to a single unit in this Plan. Reference to % protected includes existing Type 1 Open Space at the time of permit issuance in addition to critical habitat preserved during the permit term.

at the time of acquisition, proximity to occupied habitat, and prevalence of cool microsites with the proper slope, aspect, and microclimate for Bay checkerspot butterflies. All land protected will be enhanced, as described below. See Chapter 4, Section 4.7.1 *Bay Checkerspot Butterfly*, for a discussion regarding the limitations of land acquisition in specific Bay checkerspot critical habitat units.

Most of the serpentine areas in the study area are expected to be acquired as part of the Reserve System (see above). While the allowable impacts to serpentine bunchgrass grassland is limited to 550 acres (**Table 4-2**), impacts to Bay checkerspot butterfly modeled habitat mapped (see **Appendix D** and **Table 5-7**) as “occupied” or “potential” are capped at 300 acres (**Table 4-4**). Impacts to modeled habitat mapped as “historic/unoccupied” and “occupancy unknown” are not subject to this cap. In addition, impacts to Bay checkerspot butterfly modeled habitat is limited to no more than 3% of the unprotected portion (everything except Type 1 open space) of any core or satellite habitat unit targeted for conservation (as defined in **Table 5-7**). The one exception is the Kirby/East Hills core habitat unit which has an 11% allowance to accommodate the Kirby Landfill expansion (80 acres). Therefore, impacts to Bay checkerspot butterfly modeled habitat are limited in total amount (up to 4% of total modeled habitat) and in geographic scope (no more than 3% of any one core or satellite habitat unit targeted for conservation with one exception). These caps do not apply to habitat units in Type 1 open space because loss of habitat will be extremely limited in permanently protected open space (i.e., limited to trail construction and management activities).

Some impacts on serpentine grassland may still occur. Because of the high importance and rarity of serpentine soils and their habitats, these areas will be avoided whenever feasible during project planning (see Chapter 6, Section 6.5, subheading *Condition 13 Serpentine and Associated Covered Species Avoidance and Minimization*).

In the study area, an estimated 12% of designated critical habitat for Bay checkerspot butterfly is currently protected as Type 1 open space and another 25% occurs in open space Types 2, 3, and 4 (**Table 5-21**). Portions of the critical habitat units have been preserved through project compensation (e.g., Silver Creek Hills) and conservation agreements and easements from private entities (e.g., Tulare Hill and Kirby Canyon Landfill). However, this leaves 38% of critical habitat outside any type of open space. The Habitat Plan will protect an estimated 66% of all critical habitat not currently protected under Type 1 open space, including existing parklands that will be incorporated into the Reserve System. When added to the currently protected portions of critical habitat, approximately 70% of Bay checkerspot critical habitat in the study area will be preserved as Type 1 open space upon successful implementation of the Habitat Plan.

## Management Techniques and Tools

The general principles for grassland management will be followed in all serpentine grassland areas (Section 5.3.3 *Grassland Conservation and Management*). All management actions in this Plan are consistent with management guidelines in the species' Recovery Plan (U.S. Fish and Wildlife Service 1998a).

Once land is protected it will be beneficially managed for Bay checkerspot butterflies. The Implementing Entity will also enhance degraded areas to benefit serpentine grasses and encourage growth of host plants and nectar sources for the butterfly through techniques such as exotic plant control and removal, beneficial livestock grazing, and prescribed burning (GRASS-2). In the study area, grazing has been shown to benefit most covered plant species and Bay checkerspot butterfly by reducing cover of invasive plants and increasing habitat for dwarf plantain, the butterfly's host plant (Weiss and Wright 2005, 2006; Santa Clara Valley Transportation Authority 2006).

It is expected that Bay checkerspot butterflies from core populations will colonize previously unoccupied areas or areas that historically supported the species but lost its habitat value (i.e., lack of grazing, etc.). If it becomes apparent that site management is adequate and natural dispersal is not occurring, the Implementing Entity may translocate individuals (i.e., assisted migration) to increase the distribution of the species in the study area. The decision of when this should occur would be made in coordination with species experts and the Wildlife Agencies. At a minimum, the Implementing Entity will propose translocation efforts if natural colonization fails after five seasons in which core populations are at above-average population sizes. In such an event, Bay checkerspot butterflies (eggs, larvae, or adults) may be translocated from core populations into suitable but unoccupied sites to reestablish populations (GRASS-7). Translocation proposals will be provided to CDFG and USFWS for review and approval before translocation efforts are implemented and will be carried out experimentally. This is an important action identified in the Recovery Plan (U.S. Fish and Wildlife Service 1998a).

Public education and outreach is also identified as an important action in the species' Recovery Plan. The Habitat Plan provides funding for a full-time public education and outreach specialist, as well as public outreach materials. As described in this chapter, the focus of the public outreach and education campaign will be to work with landowners to minimize their impacts and improve their management to benefit covered species. Because some Bay checkerspot butterfly habitat will remain in private ownership (even after full implementation of this Plan), landowner outreach will be important to ensure populations persist on these sites.

## Threats and Uncertainties

Because this Plan will protect in perpetuity the majority of the remaining occupied and suitable habitat for this species, the threat of habitat loss from development will be greatly reduced. However, there will be a continued threat from nitrogen deposition on serpentine grasslands and the encroachment of nonnative grasses and herbs. Active livestock grazing and other management will minimize these on-going (and, over time, increasing) effects. Because management and monitoring for this species has been ongoing for many years, many of the management and monitoring techniques are well established and can be applied immediately following acquisition of new lands for the Reserve System, if funds are available (see Section 5.2.5 *Land Management*). The success of translocation is unknown but it may be attempted experimentally under the Plan to address this uncertainty.

### 5.4.2 California Tiger Salamander

#### Biological Goals and Objectives

The Implementing Entity will support viable populations and contribute to the regional recovery of the California tiger salamander by increasing the number of individuals and expanding the distribution of this species within the Reserve System. This will be accomplished by protecting and enhancing land through fee title purchase or by obtaining easements that are managed as part of the Reserve System.

Within the Reserve System the amount and quality of California tiger salamander habitat will be increased and improved through restoration, enhancement and creation of breeding and upland habitat. Lands that are protected will include land cover types that provide breeding habitat like ponds and wetlands and upland habitat like grassland, oak woodland, riparian, or chaparral. Acquisition, enhancement, and restoration/creation conservation actions identified for the following natural communities will benefit California tiger salamander through upland, movement, breeding, and foraging habitat conservation and management:

- grasslands (see Section 5.3.3 *Grassland Conservation and Management*),
- chaparral and coastal scrub (see Section 5.3.4 *Chaparral and Northern Coastal Scrub Conservation and Management*),
- oak woodlands (see Section 5.3.5 *Oak and Conifer Woodland Conservation and Management*),
- riparian forest and scrub (see Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management*), and
- wetlands and ponds (see Section 5.3.7 *Wetland and Pond Conservation and Management*).

The Reserve System will be designed to maintain and improve connectivity between breeding habitat and upland habitat and to provide essential upland refugia by protecting areas with existing ground squirrel colonies or promoting new colonies in areas adjacent to known California tiger salamander breeding habitat. The Reserve System will be designed to reduce habitat fragmentation, which in turn will ensure that proper genetic exchange can occur and that the population has the opportunity to expand its distribution within the study area. In addition, the Reserve System will link California tiger salamander habitat within the study area to areas important to the species outside of the study area, such as San Francisco Public Utilities Commission Alameda Watershed properties in Santa Clara and Alameda counties and the Soap Lake region in San Benito County.

## Habitat Acquisition, Restoration, and Creation

There are 324,748 acres of California tiger salamander modeled habitat (breeding and non-breeding) within the study area. There are 97,423 acres (30%) of modeled habitat located on Type 1, 2, or 3 open space with 45,767 acres (14%) permanently protected as Type 1 open space. The Plan will acquire a minimum of 30,150 acres of modeled habitat for the Reserve System. In addition, 11,745 acres of modeled habitat will be added to the Reserve System from existing open space. This will nearly double the proportion of California tiger salamander modeled habitat in the study area in Type 1 open space (to 27%) and increase Type 1, 2, or 3 open space to 39% (**Table 5-17**). This includes 195 acres of modeled breeding habitat (150 acres of newly acquired land and 45 acres of existing open space incorporated into the Reserve System) and 41,700 acres of modeled upland habitat (30,000 acres of newly acquired land and 11,700 acres of existing open space incorporated into the Reserve System).

The Implementing Entity will protect (through acquisition or easement) and enhance a minimum of 50 acres of ponds that either support, or have the potential to support, breeding California tiger salamander. In addition, a minimum of 20 acres of ponds will be created that either support or have the potential to support breeding California tiger salamander. Up to 104 acres of ponds will be protected and enhanced and up to 72 acres of ponds will be created if all estimated impacts occur (**Tables 4-4, 5-13, and 5-21**).

Similarly, the Implementing Entity will protect and enhance a minimum of 15 acres of wetlands (perennial and seasonal) that either support or have the potential to support breeding California tiger salamanders. Up to 80 acres of wetlands will be protected and enhanced and up to 75 acres of wetlands (perennial and seasonal) will be restored if all estimated impacts occur. As described in the species account in **Appendix D**, seasonal wetlands are more likely to support adequate breeding habitat for California tiger salamander because nonnative predators and hybrid salamanders are less likely to persist in these habitats. However, some perennial wetlands may still support California tiger salamander if they are periodically drained or nonnative predators are controlled in other ways (see the section below for a discussion of management of these ponds and wetlands to support California tiger salamander.)

By the time the Reserve System is fully acquired (which will be at or before Year 45), a minimum of 30% of all ponds and wetlands in the Reserve System will be or will have been occupied by California tiger salamander, as described in the Section 5.3.1 *Land Acquisition and Restoration Actions* subheading *Acquisition of Occupied Habitat for Select Wildlife Species*. By Year 30, at least 25% of all ponds and wetlands will be occupied or will have been occupied by the species.

Further, the Implementing Entity will protect grassland, oak woodland, riparian, or chaparral habitat within California tiger salamander modeled habitat (*California tiger salamander*, **Appendix D**) to provide upland refugia for the species. Land acquisition of modeled upland habitat for California tiger salamander will occur in all of the focus areas described below and will be adjacent to modeled breeding habitat. In most cases when modeled breeding habitat is acquired, modeled upland habitat will also be acquired because it will occur on the same parcel.

Land acquisition will substantially benefit California tiger salamander by protecting existing modeled breeding and upland habitat, protecting known occurrences, enhancing habitat through improved management, and providing opportunities for restoration of breeding habitat (freshwater wetlands) and creation of breeding habitat (ponds). To maximize the benefits of acquisition for this species, the Implementing Entity will acquire aquatic and upland modeled habitat in areas adjacent to existing open space with known occurrences of California tiger salamander such as Joseph D. Grant County Park, Palassou Ridge Open Space Preserve, or Henry W. Coe State Park (LAND-WP5).

Portions of the critical habitat units have already been preserved through acquisition and conservation easements (**Figure 4-4**). **Table 5-21** shows that 23% of all critical habitat in the study area is currently protected as Type 1 open space and another 33% is located in space Types 2–4. However, this leaves 41% of critical habitat outside of any type of open space. The Habitat Plan anticipates protecting an estimated 31% of all critical habitat in the study area within the Reserve System, including existing parklands that will be incorporated into the Reserve System. Land acquisition and incorporation of existing open space into the Reserve System will occur in 7 of 8 critical habitat units within the study area<sup>30</sup>, substantially contributing to species recovery in the study area. See Chapter 4, Section 4.7.2 *California Tiger Salamander*, for a discussion regarding the limitations of land acquisition in specific California tiger salamander critical habitat units.

Within the Diablo Range, land acquisition will be focused on protecting the connection between the southern parts of Henry W. Coe State Park, an area with high California tiger salamander densities, to the Soap Lake region in northern San Benito County. Some of the land acquired in this area falls within Critical Habitat Unit 12 and would include up to three known occurrences. Unit 11 is

<sup>30</sup> Subunits EB\_10A and B were counted as one unit. The remaining critical habitat unit in the study area (Unit 9) is almost entirely contained within the Palassou Ridge Open Space (owned by the Open Space Authority) and Coyote Lake-Harvey Bear Ranch County Park.

almost entirely within Henry W. Coe State Park (94%), so the unprotected area may or may not be incorporated into the Reserve System (for this analysis, it is assumed to not be incorporated). Land acquisition will also occur within Unit 7 along lower San Felipe Creek and along Coyote Ridge, protecting up to 7 known occurrences. By bringing most of Joseph D. Grant County Park into the Reserve System (**Table 5-5**), protection and management is enhanced within much of Unit 6 (Grant Park supports up to 14 known occurrences, most of which would be brought into the Reserve System). Another connection will be protected between Alum Rock Park and the Blue Oak Ranch in the northeastern part of the study area (Coyote-7 and Alameda-1). Land acquisition in this area would protect a small portion of Critical Habitat Unit 5 and one known occurrence. Additional populations are likely to be found in this area due to a high density of ponds and a high concentration of known occurrences nearby on existing open space.

The Santa Cruz foothills are another area where acquisition will benefit the California tiger salamander. Though salamander densities are low in the Santa Cruz Mountains when compared to the Diablo Range, protecting the remaining breeding and upland habitat is important in order to retain genetic diversity among the populations in the study area. Retaining connectivity between Uvas Reservoir and Calero County Park would benefit many species, including the California tiger salamander. Acquisitions west of Calero Reservoir will buffer California tiger salamander habitats against urban development in southern San José and also protect the only piece of Critical Habitat Unit 8 that falls outside of Calero County Park. By bringing a portion of Calero County Park into the Reserve System (**Table 5-5**), protection and management is enhanced within the rest of Unit 8. Land acquisition in this area also protects two known occurrences of the species.

Acquisitions targeted north of Gilroy would entirely protect Critical Habitat Unit 10b<sup>31</sup>, including up to three known occurrences. Substantial land acquisition in the Santa Cruz Mountains at the southern end of the study area (Uvas-5 and 6) would protect large stands of annual grassland (i.e., suitable upland habitat), a high density of ponds (i.e., suitable breeding habitat), and up to four known occurrences.

To ensure habitat connectivity within the study area the Implementing Entity will also protect modeled upland habitat between existing ponds and wetlands to provide a linked matrix of pond, wetland, and upland habitat as part of the Reserve System (LAND-G2, LAND-OC1, LAND-OC2, LAND-OC3, LAND-OC4, LAND-OC5). Acquisition will be prioritized to retain or improve habitat connectivity between breeding California tiger salamanders in the Santa Cruz foothills and in the Diablo Range. To accomplish this, the Implementing Entity will acquire land near the Santa Teresa Hills and Tulare Hill as well as areas along the Pajaro River south of Gilroy (LAND-WP7). The Implementing Entity will create at least 20 acres of ponds at 40 locations to increase available habitat and enhance connectivity among existing ponds and wetlands within the Reserve System (POND-9). Pond creation will occur regardless of the level of impacts on

<sup>31</sup> Unit 10a encompasses many small parcels that are not feasible to acquire at this time.

pond habitat. The purpose is to contribute to the recovery of the California tiger salamander in the study area. In addition to this pond creation the Implementing Entity will create ponds lost to covered activities, in-kind within the Reserve System, at a ratio of 1-acre of conservation to 1-acre of impact (1:1) (estimated to be 52 acres) (POND-10). An estimated 72 acres of ponds will be created to mitigate this impact (**Tables 5-13 and 5-21**). The total allowable impact on California tiger salamander modeled breeding habitat during the permit term is 77 acres of permanent impacts and 14 acres of temporary impacts, for a total of 91 acres (**Table 4-4**). To offset these impacts, a minimum of 195 acres of modeled breeding habitat will be protected and managed as part of the Reserve System to offset these impacts (**Table 5-17**). To achieve the biological goal for the California tiger salamander, acquisition of wetlands and ponds will be prioritized by: (1) sites with documented records of breeding California tiger salamander, (2) sites with known occurrences, though not necessarily breeding, and (3) sites without known occurrences of California tiger salamander but with pond turtle habitat and known occurrences of other covered species.

Within the Reserve System the Implementing Entity will restore 20 acres of perennial wetlands and create 20 acres of ponds (in 40 locations) (**Tables 5-13 and 5-21**) in areas within the typical dispersal distance of known breeding sites to create new breeding opportunities for this species (POND-7, POND-8, POND-9) (**Appendix D**). These wetlands and ponds will contribute to the recovery of the species while additional wetlands and ponds will be created to replace those lost to covered activities. See Section 5.3.7 *Wetland and Pond Conservation and Management* for details on restoration. This will further serve to reduce habitat fragmentation and promote genetic exchange within the population. The locations selected for wetland restoration and pond creation will be determined on the basis of physical processes, including hydrologic, geomorphic, and soil conditions to ensure that successful restoration or creation can occur and be self-sustained.

## Management Techniques and Tools

In order to increase the habitat quality of modeled upland habitat the Implementing Entity will continue or introduce livestock grazing within grassland communities in the Reserve System in a variety of grazing regimes (GRASS-1, LM-11). Other techniques that will be employed to reduce nonnative vegetation and increase the quality of upland habitat for California tiger salamander include prescribed burns (GRASS-2) and the selective application of herbicides or other treatments (e.g., hand or mechanical removal) to reduce the biomass of nonnative vegetation and increase the success of native vegetation (LM-14). To further increase the quality of modeled upland habitat, native grasses will be planted around the perimeter of ponds and wetlands (POND-3).

Fencing that allows for covered species passage will be installed on portions of ponds and wetlands to reduce grazing pressure and feral pig access to provide vegetated refuge sites for native amphibians (POND-1). If entire ponds or wetlands need to be fenced, alternate water sources will be provided for livestock. These fences will also serve to protect breeding habitat from

destruction from feral pigs. Additional measures will be implemented like trapping, hunting or other control methods, to reduce the feral-pig when feral pigs are hindering the Implementing Entity's ability to achieve the biological goals and objectives of the Plan (LM-12).

The Implementing Entity will increase the quality of modeled breeding habitat within the permit area by periodically clearing vegetation or removing sediment (POND-4) to create a variety of microhabitats within a single pond or wetland. This will provide shallow areas for California tiger salamander larvae while also accommodating other native aquatic species (POND-13). The Implementing Entity will also reduce nonnative predators (bullfrogs, invasive fish). It will use a variety of management techniques, which include habitat manipulation (e.g., periodic draining of ponds and other wetlands), trapping, hand capturing, and electroshocking to reduce nonnative predator populations (LM-13). Other techniques may be employed upon the approval of the USFWS and CDFG. New ponds will be designed to rely on passive management (e.g., dry on their own periodically), minimizing the need for artificial draining, or minimal management (e.g., stock pond dams fitted with drainage structures).

## Threats and Uncertainties

Although expected, it is uncertain whether acquiring and managing land to favor California tiger salamander will ultimately result in the species expanding its range within the study area. One limiting factor might be the presence of fossorial rodents (e.g., California ground squirrels) in upland habitats. California tiger salamanders depend on the underground refugia provided by these burrowing mammals, and without them, upland habitats are less suitable. In general, where burrowing rodents are lacking in the ecosystem it is due to human-caused eradication, but in some cases other environmental factors may influence whether fossorial rodents are present (e.g., soil, slope, water table). In addition, there may be cases where a portion of potential upland habitat is in a parcel adjacent to an acquired parcel containing potential breeding habitat. These factors will be considered when adding lands to the Reserve System to contribute to the recovery of California tiger salamander.

Since this Plan will both increase the connectivity between breeding sites and increase the frequency of surveys in the permit area it also has the potential to facilitate the spread of detrimental environmental factors (e.g., chytrid fungus, nonnative predators). To minimize this impact, Condition 4, *Stream Avoidance and Minimization for In-Stream Projects*, and Condition 12, *Wetland and Pond Avoidance and Minimization*, outline measures to be used by anyone working or studying in aquatic habitats. If ponds, wetlands, and the native amphibian populations that they support, become infected with chytrid fungus or other diseases, the Implementing Entity will use the best scientific information available to manage and stop the spread of the epidemic (STUDIES-7). Further, the Implementing Entity will conduct a risk assessment, using the best information available, when siting California tiger salamander breeding habitat to determine the risk of increasing the nonnative predator population (i.e., potential of bullfrog colonization of the new breeding site).

## Hybridization with Nonnative Salamanders

Barred salamander (*Ambystoma tigrinum mavortium*) is native to parts of Texas, eastern New Mexico, Oklahoma, Kansas, Nebraska, eastern Wyoming, and Colorado. It has been found in isolated locations throughout much of California, including Santa Clara County. The barred salamander is much larger than the California tiger salamander (it is the second largest salamander in the United States) and exhibits different behavior and life-history traits than the California tiger salamander. Native California tiger salamanders and introduced barred tiger salamanders are capable of inter-breeding (hybridizing) and have been hybridizing for 50–60 years (Fitzpatrick and Shaffer 2007). This hybridization is a major threat to California tiger salamanders.

Barred tiger salamander adults retain juvenile traits such as gills when they breed in aquatic habitats. These individuals, called “paedomorphs,” provide the opportunity to readily distinguish barred salamanders and hybrids from native California tiger salamanders in breeding ponds and wetlands. Hybridization and introgression between the California tiger salamander and the barred tiger salamander is most likely occurring at many breeding sites throughout Santa Clara County, especially in the southern portion of the county (e.g., Bluestone Lake, North Fork Pacheco Creek) at areas located within close proximity to introduction sites (**Appendix K** *California Tiger Salamander Hybridization*).

**Appendix K** provides a management, monitoring, and adaptive management strategy for California tiger salamanders and hybrids. Key components of the strategy include management, public education, outreach, and targeted studies in close coordination with the Wildlife Agencies.

The initial management strategy for hybrids will focus on restoring and maintaining wetland and pond conditions within the Reserve System that favor California tiger salamanders. Perennial breeding sites studied in the hybrid zone often contained paedomorphic tiger salamanders, relative to more seasonal aquatic sites like vernal pools (Fitzpatrick and Shaffer 2004). Therefore, initial restoration actions will target sites where paedomorphs have been observed because presence of paedomorphs would indicate presence of nonnative alleles in the tiger salamander population. Since different individual tiger salamanders are expected to return to breeding ponds every year, these targeted perennial ponds will be periodically drained to control nonnative introductions. The adaptive management process will be used to adjust monitoring and management as described in **Appendix K**.

New nonnative salamander introductions are caused by humans, and therefore could be decreased with a public education campaign. Public education will be conducted to inform the public that the use of any salamander as bait in the State of California is illegal (POND-12). The Implementing Entity will also conduct education and outreach to pond landowners, provide technical assistance, and offer financial and regulatory (Safe Harbor Agreement) incentives to private landowners to restore, create, and maintain breeding habitat conditions on their land that favor native California tiger salamanders (POND-11). Finally, the Plan will contribute toward research to determine the distribution of, and ecological

effects resulting from, introgression and interbreeding of native and nonnative tiger salamanders (e.g., effects due to competition [lower growth rates, adult survival]; effects due to predation; effects due to reduced fitness of hybrids) and effect on covered amphibians and reptiles (STUDIES-8). These studies will be coordinated with, and be complementary to, similar studies conducted outside of the purview of this Plan. With Wildlife Agency approval, the Implementing Entity will incorporate specific management prescriptions supported by this research, and research conducted by others, in the applicable reserve unit management plans.

### 5.4.3 California Red-Legged Frog

#### Biological Goals and Objectives

The Implementing Entity will support viable populations and contribute to the regional recovery of the California red-legged frogs by increasing the number of individuals and expanding the distribution of this species within the Reserve System. This will be accomplished by protecting land through fee title purchase or by obtaining easements that are managed as part of the Reserve System.

Within the Reserve System the amount and quality of California red-legged frog habitat will be increased and improved through restoration, enhancement and creation of breeding and upland habitat. The Reserve System will be designed to maintain connectivity between breeding habitat and upland habitat and to provide essential short-term upland refugia as well as dispersal habitat by protecting landcover types that provide breeding habitat like ponds and wetlands and upland refugia and dispersal habitat like grassland, oak woodland, riparian, or chaparral. Acquisition, enhancement, and restoration/creation conservation actions identified for grasslands (see Section 5.3.3 *Grassland Conservation and Management*), chaparral and coastal scrub (see Section 5.3.4 *Chaparral and Northern Coastal Scrub Conservation and Management*), oak woodlands (see Section 5.3.5 *Oak and Conifer Woodland Conservation and Management*), riparian forest and scrub (see Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management*), and wetlands and ponds (see Section 5.3.7 *Wetland and Pond Conservation and Management*) will benefit California red-legged frog through upland, movement, breeding, foraging and year-round habitat conservation and management.

In addition, the Reserve System will link California red-legged frog habitat within the study to areas important to the species outside of the study area, like San Francisco Public Utilities Commission Alameda Watershed properties in Santa Clara and Alameda counties and the Soap Lake region in San Benito County.

## Habitat Acquisition, Restoration, and Creation

There are 341,773 acres of California red-legged frog modeled habitat (primary and secondary habitat) within the study area. A total of 101,164 acres (30%) of that modeled habitat are located in Type 1, 2, or 3 open space with 46,253 acres (14%) permanently protected as Type 1 open space. The Plan proposes to acquire a minimum of 31,300 acres of modeled habitat for the Reserve System. In addition, 11,930 acres of modeled habitat for California red-legged frog will be added to the Reserve System from existing open space. These acquisitions and additions will increase the proportion of protected habitat in the study area to about 26% in Type 1 open space and 39% in Type 1, 2, and 3 open space (**Table 5-17**). The Reserve System will include 1,430 acres of modeled primary habitat and 41,800 acres of modeled secondary habitat.

The Implementing Entity will protect (through acquisition or easement) and enhance a minimum of 50 acres of ponds that support or have the potential to support breeding California red-legged frogs. In addition, a minimum of 20 acres of ponds will be created to support aquatic covered species and tri-colored blackbird. Up to 104 acres of ponds will be protected and enhanced and up to 72 acres of ponds will be created if all estimated impacts occur (**Tables 5-13 and 5-21**). Similarly, the Implementing Entity will protect and enhance a minimum of 10 acres of perennial wetlands and up to 50 acres of perennial wetlands that either support or have the potential to support aquatic covered species and tri-colored blackbird. A minimum of 20 acres of perennial wetlands will be restored to support aquatic covered species and tri-colored blackbird. Up to 45 acres of perennial wetlands will be restored if all estimated impacts occur. In addition, a minimum of 100 miles of streams will be protected that either support or have the potential to support breeding California red-legged frogs, breeding foothill yellow-legged frogs, and/or foraging/basking western pond turtles. A minimum of 1 mile of streams will be restored that have the potential to support these same species. Up to 10.4 miles of streams will be restored if all estimated impacts occur. Further, it will protect grassland, oak woodland, riparian, or chaparral habitat within the California red-legged frog modeled habitat (*California red-legged frog*, **Appendix D**) to provide upland refugia and dispersal opportunities for the species. To maximize benefits to the species the Implementing Entity will target acquisitions in the East San Francisco Bay Recovery Unit (U.S. Fish and Wildlife Service 2002) (LAND-WP4) and in areas adjacent to existing open space with known occurrences of California red-legged frog, such as Joseph D. Grant County Park or Palassou Ridge Open Space Preserve (LAND-WP5).

In the Diablo Range, land will be acquired along Coyote Ridge to ensure that an area with high concentrations of California red-legged frogs is protected. Up to 15 known occurrences (breeding sites or movement locations) on Coyote Ridge could be preserved. The Implementing Entity will also target acquisition of parcels northeast of Alum Rock Park to connect Alum Rock Park and Cherry Flat Reservoir (Alameda-1 and Coyote-7) with protected open space outside the study area (i.e., San Francisco Public Utilities Commission Alameda Watershed). This will also protect suitable habitat for this species and up to one known occurrence in Critical Habitat Units STC-1 and STC-2 (75 FR 12815 12959). Incorporation of most of Joseph Grant County Park into the Reserve System will provide

substantial opportunity to enhance suitable and occupied breeding habitat (**Table 5-5**). The portion of Grant Park proposed for the Reserve System supports at least two known occurrences of the species.

Portions of the critical habitat units have already been preserved through acquisition and conservation easements (**Figure 4-5**). **Table 5-21** shows that 24% of all critical habitat in the study area is currently protected as Type 1 open space and another 14% is located in open space Types 2–4. However, this leaves 62% of critical habitat outside of any type of open space. The Habitat Plan anticipates protecting an estimated 14% of all critical habitat in the study area within the Reserve System, including existing parklands that will be incorporated into the Reserve System.

Additional target areas of land acquisition that will benefit this species and support implementation of the Recovery Plan include the area between Henry W. Coe State Park and the Soap Lake region of San Benito County (LAND-WP5). This area is important for many covered species and will help retain a connection between breeding populations in the state park and in areas outside of the study area. Although there are no known occurrences in this area due to a lack of survey effort, there is a high density of ponds, many of which are expected to be suitable breeding habitat.

Land acquisition in the Pacheco Watershed will protect high densities of suitable ponds and other wetlands, including up to three known occurrences of California red-legged frogs. Protection of the creek and the associated riparian areas will increase the level of protection of breeding and movement habitat in this part of the study area. Further, this area likely provides an important movement corridor between the Soap Lake region of San Benito County to areas northeast in Santa Clara County such as Romero Ranch and Pacheco State Park.

By the time the Reserve System is fully acquired (which will be at or before Year 45), a minimum of 40% of all ponds and wetlands in each of the federal Recovery Units 4 and 6 in the Reserve System will be or will have been occupied by California red-legged frog, as described in the Section 5.3.1 *Land Acquisition and restoration Actions* subheading *Acquisition of Occupied Habitat for Select Wildlife Species*. By Year 30, at least 35% of all ponds and wetlands in each of the federal Recovery Units 4 and 6 will be occupied or will have been occupied by the species.

There is no designated critical habitat for California red-legged frog in the Santa Cruz Mountains. However, land acquisition in this area will protect a substantial amount of suitable breeding, aestivation, and movement habitat. For example, land acquisition around Calero Lake, Chesbro Reservoir, and Uvas Reservoir will protect suitable habitat, some of which is within a mile of known occurrences. Land acquisition in the south end of the study area will protect up to four known occurrences and a high density of ponds and other wetlands suitable for California red-legged frog breeding.

To achieve the biological goal for the California red-legged frog, acquisition of wetlands, ponds, and streams will be prioritized by: (1) sites with documented

records of breeding California red-legged frog, (2) sites with known occurrences, though not necessarily breeding, and (3) sites without known occurrences of California red-legged frogs but with pond turtle habitat and known occurrences of other covered species.

The Implementing Entity will create at least 20 acres of ponds at 40 locations to increase available habitat and enhance connectivity among existing ponds and wetlands within the Reserve System (POND-9). Pond creation will occur regardless of the level of impacts on pond habitat by covered activities. The purpose of this habitat creation is to contribute to the recovery of the California red-legged frog in the study area. In addition to pond creation the Implementing Entity will create ponds lost to covered activities, in-kind within the Reserve System, at a ratio of 1-acre of creation to 1-acre of impact (1:1) (estimated to be 52 acres) (POND-10). Together with the minimum creation requirements, up to 72 acres of ponds (minimum of 20 acres plus 52 acres to offset impacts) will be created within the Reserve System (**Tables 5-13 and 5-21**).

The Implementing Entity will also restore at least 20 acres of perennial wetlands within the Reserve System. All of this will be characterized as coastal and valley freshwater marsh (POND-6) and will be restored regardless of the level of impacts to wetlands in the study area from covered activities. In addition to those 20 acres, the Implementing Entity will restore impacted perennial freshwater wetlands “in-kind” at a ratio of one-acre of conservation to one-acre of impact (1:1) (POND-7) (estimated to be 25 acres). The Implementing Entity will also restore impacted seasonal wetlands “in-kind” at a ratio of two-acres of conservation to one-acre of impact (2:1) (POND-8) (estimated to be 30 acres). Restoration will be carried out in areas that will increase available habitat and enhance connectivity among existing ponds and wetlands within the Reserve System.

## Management Techniques and Tools

Since the California red-legged frog utilizes pond and wetland habitats, as well as riverine habitats within the study area, management actions that enhance and restore those natural communities will benefit this species. In addition, many of the management actions outlined for the California tiger salamander will benefit the California red-legged frog. For a description of the management techniques that will be implemented to increase the quality and quantity of California red-legged frog habitat within the Reserve System refer to Section 5.4.2, *California Tiger Salamander* subheading *Management Techniques and Tools*, above. In addition, the Implementing Entity may utilize translocation of California red-legged frog to help establish new populations in the study area. This activity will only be undertaken with the approval of the Wildlife Agencies, and when biologically appropriate and necessary to meet biological goals and objectives of the Plan.

For a general description of pond, wetland, and riverine restoration, creation, and management refer to Sections 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management* and 5.3.7 *Wetland and Pond Conservation and*

*Management*, above. All management actions in this Plan are consistent with management guidelines in the species' Recovery Plan (U.S. Fish and Wildlife Service 2002).

## Uncertainties and Threats

Since this Plan will both increase the connectivity between breeding sites and increase the frequency of surveys in the permit area it also has the potential to facilitate the spread of detrimental environmental factors (e.g., chytrid fungus, nonnative predators). If ponds, wetlands, and the native amphibian populations that they support, become infected with chytrid fungus or other diseases, the Implementing Entity will use the best scientific information available to manage and stop the spread of the epidemic (STUDIES-7). Further, the Implementing Entity will use the best information available to determine whether the benefits of creating more California red-legged frog breeding habitat in an area outweighs the risk of increasing the nonnative predator (i.e., bullfrogs) population along with it.

### 5.4.4 Foothill Yellow-Legged Frog

#### Biological Goals and Objectives

The goal of the Implementing Entity will be to maintain or increase the population of foothill yellow-legged frog in the study area. The objectives toward meeting that goal are to acquire, through fee title or conservation easement, streams that have or historically had perennial flows. Additionally, the Implementing Entity will enhance or restore perennial streams to provide higher quality habitat for all riverine species, including foothill yellow-legged frog. Acquisition, enhancement, and restoration/creation conservation actions identified for streams and riparian forest and scrub (see Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management*), and redwood forests (see Section 5.3.5 *Oak and Conifer Woodland Conservation and Management*) will benefit foothill yellow-legged frog through movement, foraging, and year-round habitat conservation and management.

#### Acquisition, Restoration, and Enhancement

There are 690 miles of foothill yellow-legged frog modeled primary and secondary habitat within the study area. A total of 222 stream miles (32%) of modeled primary and secondary habitat are located on Type 1, 2, or 3 open space with 119 stream miles (17%) permanently protected as Type 1 open space. The Plan proposes to acquire a minimum of 80 miles of primary and secondary modeled habitat for the Reserve System. In addition, 24 miles of primary and secondary modeled habitat will be added to the Reserve System from existing open space. These acquisitions and additions will increase the proportion of total

protected primary and secondary modeled habitat in the study area to about 32% in Type 1 open space and 44% in Type 1, 2, or 3 open space (**Table 5-17**).

The Implementing Entity will target acquisition of streams that currently have, or historically had, perennial flows and cobblestone substrate (LAND-R5) along with intermittent and ephemeral streams that connect to those perennial streams. A recent study in Tehama County has revealed that foothill yellow-legged frogs utilize perennial systems primarily but also use associated intermittent and ephemeral streams within the same watershed (Bourque 2008). These stream reaches will be located along:

- Uvas/Carnadero Creek above Uvas Reservoir,
- small creeks above Calero Reservoir,
- Alamitos and Guadalupe Creeks upstream and outside of urban San José,
- Llagas Creek above Chesbro Reservoir,
- San Felipe Creek, above Anderson Reservoir,
- Uvas Creek below Uvas Reservoir,
- Little Arthur Creek,
- Upper Penitencia Creek.

Occupied habitat for foothill yellow-legged frog will be protected in the Reserve System in at least four of the watersheds in **Figure 3-6**, in both the Diablo Range and in the Santa Cruz Mountains (as described in the Section 5.3.1 *Land Acquisition and Restoration Actions* subheading *Acquisition of Occupied Habitat for Select Wildlife Species*). The Reserve System is expected to protect at least four known occurrences of the species, three on Llagas Creek above Chesbro Reservoir, and one on San Felipe Creek above Anderson Reservoir. Additional occurrences may be found in the Reserve System on Upper Penitencia Creek, Uvas Creek below Uvas Reservoir, and Little Arthur Creek due to their proximity to known occurrences in the same stream systems and the lack of survey effort for the species in those areas. To achieve the biological goal for the foothill yellow-legged frog, acquisition of streams will be prioritized by: (1) sites with documented records of breeding foothill yellow-legged frog, (2) sites with known occurrences, though not necessarily breeding, and (3) sites without known occurrences of foothill yellow-legged frogs but with pond turtle habitat and known occurrences of other covered amphibian species.

The Implementing Entity will restore a minimum of 1 mile of stream to support breeding yellow-legged frogs, breeding California red-legged frogs, and/or foraging/basking western pond turtles regardless of the level of impact (**Table 5-13**). Up to 10.4 miles of stream will be restored if all estimated impacts occur (**Table 5-13**). This could include the perennial stream reaches mentioned above. For foothill yellow-legged frogs this restoration will involve adding sufficient sediment to stream courses so that sand bars will form to create egg laying substrate, or adding large rocks to the stream course for the same purpose. Management will include selectively applying herbicides or other treatments to

control nonnative invasive vegetation along creek corridors (LM-14) that might inhibit sediment movement and restrict the creation of egg laying habitat.

## Management Techniques and Tools

Foothill yellow-legged frogs require streams with fast moving water and cobblestone substrate. Channel rehabilitation will increase the amount of this type of habitat that is available in the study area. The Implementing Entity will replace concrete, earthen or other engineered channels to restore floodplain connectivity (STREAM-4, STREAM-5). This gives the frog some areas of slower flow or other a natural habitats adjacent to the stream, in which to take refuge during high water. It also allows the streams to form gravel bars, behind which this species often lays eggs. To further enhance these rehabilitated channels the Implementing Entity will plant and/or seed in native understory and overstory riparian vegetation within 15 feet of the edge of the low-flow channel to create structural diversity, provide overhead cover, and moderate water temperature (STREAM-2). This can be done in other reaches as well, where there is an unnatural void in riparian vegetation. In all streams mentioned above there will be opportunities to increase the amount of cobblestone substrate by actually adding rocky substrate to the stream channel (STREAM-8). Gravel augmentation will avoid the breeding season. This management action will be applied to areas close to known occurrence(s) of foothill yellow-legged frog or immediately upstream or downstream of known occurrences or other high quality foothill yellow-legged frog breeding habitat.

The Implementing Entity may utilize translocation of foothill yellow-legged frog to help establish new populations in the study area. This activity will only be undertaken with the approval of the Wildlife Agencies, and when biologically appropriate and necessary to meet biological goals and objectives of the Plan.

## Threats and Uncertainties

The biggest threat to foothill yellow-legged frog is continued alteration of the hydroperiod of streams within the study area. Managing for this species downstream of reservoirs in northern watersheds is difficult because flows are controlled as part of a water delivery system to the City of San José. Restoration and management efforts will always be subject to whether there is enough water to support perennial flows in these watersheds. In the southern watershed there are fewer limitations on how and when the water is released out of reservoirs. Still managing riverine systems downstream of reservoirs is not a guaranteed solution every year. Augmenting streams with cobblestone substrate to increase the amount of breeding habitat for this species is a short-term solution unless accompanied by complimentary land management practices upstream that can sustain the flows and sediment delivery. If there are uncontrolled sources of sediment upstream then the habitat quality will continue to be diminished, eggs could be silted in, or egg laying habitat could be removed as the stream changes course in reaction to high sediment deposition. If the stream is not in a relatively

natural condition then flows during high water events will continue to degrade the habitat even after cobblestone substrate is added.

Global climate change could impact this species through changes in the amount of precipitation and therefore the amount of surface water in occupied streams. Areas that receive less rainfall will support less high-quality habitat for foothill yellow-legged frog in the future. One benefit of the Reserve System is that species will have more ability to move away from areas that are less suitable and into areas that are more suitable over the long-term. Protecting small, isolated breeding locations for this species might not adequately protect the species over the long term if rainfall patterns change stream hydrology.

Watersheds with a high level of agricultural production were associated with the decline of the species, due to airborne agro-chemicals (Lind 2005). In general, the Reserve System is far from agricultural production that uses pesticides, raising the chance of achieving the biological goals and objectives for this species.

## 5.4.5 Western Pond Turtle

### Biological Goals and Objectives

The Implementing Entity will support viable populations and contribute to the regional recovery of the western pond turtle by maintaining or increasing the number of individuals and expanding the distribution of this species within the Reserve System. This will be accomplished by protecting land through fee title purchase or by obtaining easements that are managed as part of the Reserve System. Within the Reserve System the amount and quality of western pond turtle habitat will be increased and improved through restoration, enhancement, and creation of basking habitat and breeding sites. Acquisition, enhancement, and restoration/creation conservation actions identified for grasslands (see Section 5.3.3 *Grassland Conservation and Management*), chaparral and coastal scrub (see Section 5.3.4 *Chaparral and Northern Coastal Scrub Conservation and Management*), oak woodlands (see Section 5.3.5 *Oak and Conifer Woodland Conservation and Management*), riparian forest and scrub (see Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management*), and wetlands and ponds (see Section 5.3.7 *Wetland and Pond Conservation and Management*) will benefit western pond turtle through movement, breeding, foraging and year-round habitat conservation and management.

### Habitat Acquisition, Restoration, and Creation

There are 314,916 acres of western pond turtle modeled habitat (primary and secondary) within the study area. A total of 98,060 acres (31%) of that modeled habitat are located in Type 1, 2, or 3 open space with 44,967 acres (14%) permanently protected as Type 1 open space. The Plan proposes to acquire a minimum of 27,000 acres of modeled habitat for the Reserve System. In

addition, 11,900 acres of modeled habitat will be added to the Reserve System from existing open space. These acquisitions and additions will increase the proportion of protected modeled habitat in the study area to about 27% in Type 1 open space and about 40% in Type 1, 2, or 3 open space (**Table 5-17**).

The Implementing Entity will protect, through acquisition or easement, and enhance a minimum of 50 acres of ponds, 10 acres perennial freshwater wetlands, and 100 miles of stream that either support or have the potential to support covered aquatic species, including western pond turtle. Up to 104 acres of ponds and 50 acres of perennial freshwater wetlands will be protected and enhanced if all estimated impacts (LAND-WP2a, LAND-WP2b, LAND-WP3a, LAND-WP3b, LAND-WP6a, LAND-WP6b). To achieve the biological goal for the western pond turtle, acquisition of wetlands, ponds, and streams will be prioritized by: (1) sites with documented records of breeding western pond turtles, (2) sites with known occurrences, though not necessarily breeding, and (3) sites without known occurrences of western pond turtle but with pond turtle habitat and known occurrences of other covered species. Most of the land acquisition that will benefit western pond turtle will occur along the Pacheco Creek riparian corridor and between Henry W. Coe State Park and the Soap Lake region of San Benito County. Additional acquisitions west of Chesbro reservoir and west and east of Calero Reservoir will also benefit this species, where both ponds will be acquired as well as perennial reaches of streams.

During the course of Plan implementation, the Implementing Entity will protect and enhance a minimum of 100 miles of streams and 250 acres of riparian forest and scrub to benefit aquatic covered species and least Bell's vireo. Up to 592 acres of riparian forest and scrub (including California alluvial sycamore woodland) will be protected and enhanced if all estimated impacts occur. In addition, a minimum of 1 mile of stream and 50 acres of riparian forest and scrub (including California alluvial sycamore woodland) will be restored. Up to 10.4 miles of streams and 353 acres of riparian forest and scrub will be restored if all estimated impacts occur (STREAM-4, STREAM-5).

Ponds that are lost to covered activities will be created at a ratio of 1:1 (estimated at 52 acres) within the Reserve System in (POND-10) (**Table 5-12**). In addition, the Implementing Entity will create a minimum of 20 acres of new ponds at approximately 40 locations to create new breeding opportunities for aquatic covered species and tri-colored blackbird (POND-9). The intent of these new ponds is to contribute to the recovery of the species beyond the replacement of pond habitat lost to covered activities.

By the time the Reserve System is fully acquired (which will be at or before Year 45), a minimum of 25% of all ponds and wetlands in the Reserve System will be or will have been occupied by western pond turtle, as described in the Section 5.3.1 *Land Acquisition and Restoration Actions* subheading *Acquisition of Occupied Habitat for Select Wildlife Species*. By Year 30, at least 20% of all ponds and wetlands will be occupied or will have been occupied by the species.

## Management Techniques and Tools

For a detailed discussion of the management techniques that will be implemented to increase the quality and quantity of western pond turtle habitat within the study area refer to Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation Management* and Section 5.3.7 *Wetland and Pond Conservation Management*.

In addition, the Implementing Entity will install artificial basking substrate and add woody debris to ponds that otherwise lack suitable basking sites to enhance habitat for western pond turtles (POND-2). Woody debris and artificial basking substrate enhance habitat by providing areas for turtles to thermoregulate, an essential biological function. Basking platforms might also be used when natural debris is not suitable. Basking platforms differ from woody debris in that they can be anchored, are durable, and will not be submerged by rising water levels. The basking platforms and added woody debris will also facilitate species-level monitoring by providing a consistent and stable point at which to count pond turtles. Populations of nonnative competitors such as red-eared sliders will also be reduced (Objective 19.3).

The Implementing Entity may utilize translocation of western pond turtle to help establish new populations in the study area. This activity will only be undertaken with the approval of the Wildlife Agencies, and when biologically appropriate and necessary to meet biological goals and objectives of the Plan.

## Threats and Uncertainties

A lack of nesting sites is likely the limiting factor for this species in the study area. Identifying and protecting potential nesting habitat is important to ensure recruitment of juveniles into the population (STUDIES-9). In order to accomplish that, the Implementing Entity will focus on protecting buffers around aquatic habitats that might support nesting pond turtles. That in turn should increase the productivity of this species during the permit term, though there is some uncertainty that an increase in productivity will occur. Continued alteration of streams and wetlands and continued disconnection of streams and their floodplains is the greatest threat to pond turtles. Adequate time will be given to determine whether newly created habitat is successfully replacing habitat that is lost to covered activities.

### 5.4.6 Western Burrowing Owl

A complete conservation strategy for western burrowing owl, including background information, conservation region descriptions, and expanded biological goals and objectives discussion, is provided as **Appendix M, *Western Burrowing Owl Conservation Strategy***. A summary of this strategy is provided below. Because of the unique nature of the conservation strategy for this species,

this section is organized differently than the rest of the covered species sections in this chapter.

## Background

Nesting burrowing owls in the greater San Francisco Bay Area, and the South Bay area in particular, are a dwindling resource. In the early 1990s there were an estimated 150–170 breeding pairs in the San Francisco Bay Area (DeSante and Ruhlen 1995; DeSante et al. 1993). It was estimated that these numbers represented a 53% decline from the previous census period of 1986–1990 (DeSante et al. 1997) and more recent numbers indicate that, if anything, the downward trend is increasing. In those estimates it was assumed that 75% of the San Francisco Bay Area burrowing owl population occurred in Santa Clara County and nearly all of those owls were congregated around the southern edge of the San Francisco Bay (DeSante et al. 1997). Surveys in the early 1990s revealed that about a third (43–47 pairs) of Santa Clara County breeding pairs occurred inside what is now the Santa Clara Valley Habitat Plan study area (Albion Environmental Inc. 2000).

## Overview of Burrowing Owl Conservation Strategy

The Plan proposes to undertake an aggressive suite of measures aimed at reversing the declining trend of the burrowing owl population in Santa Clara County. The goal of the Plan is to establish a burrowing owl population in the study area and the expanded study area (**Figure 5-10**) that is first stable, then increasing over time, while accounting for normal fluctuations in population levels. The general approach will be to increase the numbers, distribution, and connectivity of burrowing owl colonies in the permit area. This will be accomplished by using a phased conservation approach, initially focusing efforts on areas within immediate flight distance from known colonies while gathering data to inform future efforts. Later phases, triggered as more resources are available and in response to initial results, will focus on lands further out to allow for growth in both numbers and range. Initial techniques will include data gathering and analysis to inform management decisions, utilizing current best management practices, testing newly proposed management techniques through pilot scientific studies, acquisition of existing and potential breeding and foraging areas, management (both permanent and temporary agreements) of burrowing owl habitat and, and population augmentation.

These measures will be applied in four burrowing owl conservation regions: North San José/Baylands, South San José, Morgan Hill, and Gilroy (**Figure 5-10**). Opportunities to conduct meaningful burrowing owl conservation inside the Habitat Plan study area are limited because the most effective conservation measures must take place in near proximity to the remaining burrowing owl occurrences. Since those occurrences are clustered around the southern part of the Bay and northern San José, there is little unused land available and that which is not built on has high land values. As a result the conservation focus for

burrowing owls was expanded to include the entire Baylands region, in addition to the Habitat Plan study area (**Figure 5-10**).

Acquisition and permanent protection of land is generally infeasible in the areas most valuable for this species because of the limited availability of land and its high cost. What land is available and likely most suitable for the species is already publically owned. Therefore, to ensure enhanced management on sites to support the species and meet population growth goals, the Implementing Entity will either acquire in fee title, secure conservation easements, or secure management agreements. At least initially, limited burrowing owl habitat acquisition and/or management will occur along the southern edge of the study area and more limited conservation activities will occur in the two middle regions because of the current lack of occupied nesting burrowing owl colonies in these areas (**Figure 5-10**). If conservation actions in the North San José/Baylands region prove successful, it is reasonable to assume the nesting burrowing owl population will expand into suitable habitat in the South San José, Morgan Hill, and Gilroy regions. Management of overwintering habitat will also occur in the Reserve System.

Conservation targets for western burrowing owl that are based on habitat availability (similar to what was done for other covered wildlife species) are likely to be inadequate to ensure population recovery in the study area because of the relatively low existing population size. Instead, conservation targets for population size were developed. These population targets were then used to develop targets for the amount of habitat needed to support that population.

To determine the population target needed for burrowing owls in the Plan, a count-based population viability analysis (PVA) was used. This analysis was used to determine the probability of persistence of three burrowing owl nest colonies in the South Bay. This analysis was performed on the three largest remaining burrowing owl colonies in the South Bay Area (Moffett Airfield, San José International Airport, and Shoreline at Mountain View) using survey data of adult burrowing owls from the 11-year period of 1999–2009. These sites were chosen because they are the primary remaining population clusters and because data was available for the period of time recommended for the analysis (i.e., at least 10 years). The intent of the analysis was to quantify population size, trend, growth rate, and variance in the three burrowing owl colonies and to evaluate the probability of persistence of these colonies (individually and combined) during that 11-year period. It was assumed that the population performance at these three sites can be used as an index for population performance for burrowing owls in the Habitat Plan study area.

In order to develop a burrowing owl population size goal for the Habitat Plan, the annual population size of adult owls was artificially increased in a statistical model to determine the rate at which the numbers of adult burrowing owls at the three baseline colonies (San José International Airport, Moffett and Shoreline) would need to increase and over what period of time to change the PVA probability of extinction trend from a negative growth rate to a positive growth rate. It was determined that if currently measured population characteristics held true (i.e., growth rate and variance were constant) changing the overall number of

adult burrowing owls in this type of model did not change the probability of persistence significantly (**Appendix N**). Instead, increasing the change of population persistence was best achieved by a steady increase in the number of adult burrowing owls. Therefore, for the purposes of this Plan, growth rate is a more correct predictor of persistence than an ultimate population size.

During 2009, there were 51 adult burrowing owls observed at the three reference nest colonies. Based on these numbers and the PVA, it was determined that in order to change the population trend in the South Bay from negative to positive within a 10-year time period, there would have to be an increase of three adult owls per year. A period of at least 10 years is also needed to allow time for collection of data at occupied nest sites in the permit area and integration of that data into the PVA model. To account for these factors and to provide additional time to achieve the population targets, the Plan has a goal to achieve a positive growth rate in the burrowing owl population in South Bay Population by Year 15.

The total population of burrowing owls in the South Bay is estimated at 70 adults (51 adults at the three reference sites plus 19 adults observed in 2008 in other parts of the study area). If three burrowing owls were recruited to the population every year for the permit term, an additional 150 adults would be added, for a total population size of 220 adults. The Habitat Plan would be responsible for 70% of this population growth (154 adults at the end of the permit term) based on its proportion of the South Bay and burrowing owl population. This equates to a land management need of 5,300 acres of occupied or potential nesting habitat (see **Appendix M** for calculations) in the permit area. Of the 5,300 acres, a minimum of 600 acres of occupied nesting habitat will be protected in fee title or conservation easement. Similar to the conservation strategy for other covered species, these lands will be under permanent management agreements administered by the Implementing Entity no later than Year 45. The Plan also provides a species-specific Stay-Ahead provision for the burrowing owl (see Section 8.6.1). Priority will be given towards management on occupied habitat (**Figure 5-11**), followed by potential nesting habitat (see Chapter 4, Section 4.6.4 *Western Burrowing Owl* for habitat definitions).

Specific burrowing owl conservation actions that would occur on the 5,300 acres of occupied and potential nesting habitat are grouped into three “tiers” of priority:

- **Tier 1 conservation actions** are designed to stabilize the existing population by protecting and/or managing occupied burrowing owl nesting habitat. Tier 1 actions may indirectly increase the numbers of owls in extant colonies. Tier 1 conservation actions will take place initially in the North San José/Baylands Region where owls currently occur. Tier 1 conservation actions will occur immediately upon Plan implementation.
- **Tier 2 conservation actions** are designed to facilitate growth and expansion of existing colonies, the number of colonies, and the range of the species in the permit area by managing potential burrowing owl nesting habitat in all portions of the permit area. Tier 2 conservation actions will also take place

immediately and will initially be implemented in the North San José/Baylands Region where owls currently occur.

- **Tier 3 conservation actions** consist of more experimental and active methodologies such as population augmentation and owl relocation within the permit area to increase owl numbers and expand distribution. Tier 3 actions will be implemented in response to population performance at the three index sites (Shoreline Park in Mountain View, San José International Airport, and Moffett Federal Airfield) but these actions could occur in any of the burrowing owl conservation regions. These actions will be coordinated with the Wildlife Agencies and will only be implemented upon their approval. Upon approval, these actions could occur immediately upon implementation of the Plan and are not dependent upon the grant awards.

**Appendix M** describes the specific conservation actions proposed for the western burrowing owl conservation strategy. Examples include:

- Protect existing colonies through fee title acquisition, purchase of a conservation easement, or management agreements (Tier 1).
- Increase survival rates at existing nest colonies through focused management actions (Tier 1).
- Survey all undeveloped parcels within 7.5-miles of documented nest colonies and complete an opportunities and constraints assessment of each for the potential of the site to function as a burrowing owl reserve (Tier 2).
- Employ population augmentation techniques to increase the local population size (Tier 3).

## Biological Goals and Objectives

The Implementing Entity will work to increase the size and sustainability of the breeding and overwintering burrowing owl population and increase the distribution of breeding and overwintering burrowing owls in the permit area (**Figure 5-10**). This goal will be met by achieving a positive growth rate by Year 15 of the Plan using annual data for the San José International Airport, Moffett and Shoreline colonies or other colonies formed in the permit area. This will be accomplished by protecting land on the valley floor and in the Diablo Range in fee title purchase or by obtaining easements as part of the Reserve System, or through management agreements. Target areas will include modeled overwintering only, occupied nesting, and potential nesting habitat (LAND-G6, G7, and G8). As a result, nesting habitat will be protected or managed within four distinct geographical regions: North San José /Baylands, Gilroy, Morgan Hill, and South San José (**Figure 5-11**).

All sites protected within the Reserve System and on lands where management agreements exist will be enhanced to encourage the expansion of burrowing owls (GRASS-5, 6, 8, and 9). Acquisition, enhancement, and restoration conservation actions identified for grasslands (see Section 5.3.3 *Grassland Conservation and Management*), valley oak woodlands (see Section 5.3.5 *Oak and Conifer*

*Woodland Conservation and Management*), and seasonal wetlands (see Section 5.3.7 *Wetland and Pond Conservation and Management*) are intended to benefit western burrowing owl through breeding and foraging habitat conservation and management.

## Habitat Acquisition and Enhancement

As indicated above, the Implementing Entity will manage a minimum of 5,300 acres for the western burrowing owl nesting habitat (occupied and potential) by Year 45. Of this acreage, a minimum of 600 acres of occupied nesting habitat must be protected in fee title or conservation easement in accordance to the rough proportionality provision for the burrowing owl, described in Section 8.6.1. For the remaining 4,700 acres, land acquisition (fee title or easement) or management agreements may be used. The Implementing Entity will prioritize land acquisition over management agreements. All 5,300 acres of western burrowing owl nesting habitat will be acquired or under a permanent management agreement by Year 45.

The 5,300 acres will include burrowing owl nesting habitat within 5 miles of the San José water Pollution Control Plant bufferlands, north of Highway 237 (LAND-G6) and burrowing owl nesting habitat within 5 miles of the San José International Airport or other important northern San José breeding sites (LAND-G7). Because the North San José/Baylands region is the most important for burrowing owl conservation and has the most conservation opportunities, a goal is set for 70% (3,700 acres) of the total land management commitment occurring in that region and the expanded permit area. Further, a recommended 15% (800 acres) of the total land managed would occur in the Gilroy region. The remaining 15% should remain flexible and could occur in any of the regions, but it is assumed that 5% (270 acres) occur in the South San José region and 10% (530 acres) occur in the Morgan Hill region.

Management agreements may be used in place of land acquisition on up to 4,700 acres, if the specified regional targets cannot be met through land acquisition. During the permit term, temporary management agreements may be put into place rather than permanent management agreements. Temporary management agreements (e.g., 10–20 year agreements as opposed to agreements in perpetuity) may be used to protect nesting habitat on areas not immediately planned for development as long as the amount of land permanently protected in fee title or conservation easement is consistent with the Stay-Ahead provision (Chapter 8, Section 8.6.1 *Stay-Ahead Provision*, subheading *Rough Proportionality and Stay-Ahead for the Burrowing Owl Conservation Strategy*). By Year 45 of the permit term, all management agreements must be permanent.

The management agreements must be legally binding documents to which the Wildlife Agencies are parties. Their establishment will follow a process similar to land acquisition described in Chapter 8, Section 8.6 *Land Acquisition*. The management agreements will be consistent with the land acquisition process; however, the Implementing Entity would work with the land owner to establish the management agreement rather than acquiring the land in fee title or with a

conservation easement. The duration and management requirements will be agreed upon by all parties and specified in the management agreement document. For the permanent management agreements, management must be assured in perpetuity. For temporary management agreements, management must be assured for the duration of the agreement. As parties to the management agreements, the Wildlife Agencies will have review and approval authority.

Although the Implementing will protect and/or manage a minimum of 5,300 acres no later than Year 45 of the permit term, the preliminary goals described above regarding the distribution of these lands in the amongst the burrowing owl conservation zones may shift during the permit term upon close coordination with the Wildlife Agencies. However, the total amount of lands managed for the burrowing owl will be maintained or increase until the goals of the Plan are achieved. In other words, parcels where management for burrowing owls is discontinued need to be replaced prior to discontinuation of management with parcels of equal or better habitat value and size. The Implementing Entity will track management agreements to ensure the amount of managed lands for the burrowing owl at no time decrease during the permit term.

To ensure the burrowing owl conservation strategy's progress, the Implementing Entity will confer with the Wildlife Agencies no later than Year 15 to assess how well the strategy is meeting its intended purpose. This coordination will be in addition to the annual reporting described in Chapter 8. If it becomes evident that portions of the burrowing owl strategy will not be feasible, a Plan amendment, as described in Chapter 10, may be necessary.

In addition to managing 5,300 acres of occupied and potential nesting habitat, the Implementing Entity will also protect, through fee title or easement, modeled overwintering habitat. There are 132,770 acres of western burrowing owl overwintering modeled habitat within the permit area. A total of 28,517 acres (21%) of that modeled habitat are located in Type 1, 2, or 3 open space with 12,584 acres (9%) permanently protected as Type 1 open space. The Plan proposes to acquire a minimum of 17,000 acres of modeled overwintering habitat for the Reserve System. In addition, 4,310 acres of modeled habitat will be added to the Reserve System from existing open space. These acquisitions and additions will increase the proportion of protected overwintering habitat in the permit area to 26% in Type 1 open space and about 34% in Type 1, 2, or 3 open space (**Table 5-17**).

Modeled overwintering habitat for western burrowing owl will be permanently preserved, managed, and enhanced throughout the Reserve System in all major watersheds in the permit area. Overwintering habitat will be protected in low elevation grassland valleys in the Diablo Range that currently support California ground squirrels, have supported California ground squirrels since 1997, or are adjacent to lands with existing California ground squirrel colonies (LAND-G8). Low elevation valleys within the Reserve System that are located on the valley floor or in the Diablo Range will be managed to benefit nesting and overwintering burrowing owls. Some locations on the southern edges of the City of San José could support burrowing owls in the future. In addition, several acres will be acquired in the southern part of the permit area in the Pescadero

watershed that could be converted to annual grassland and managed for western burrowing owls. Nearly all land acquisition in areas dominated by annual grassland has the potential to benefit overwintering owls. Most of that land acquisition will occur along Coyote Ridge, west of Chesbro Reservoir, west and east of Calero Reservoir, and between Henry W. Coe State Park and the San Benito County line. This land acquisition has been primarily targeted for other covered species but will have incidental conservation benefit for western burrowing owls, especially during the winter months.

Land that is acquired through fee title purchase or easement to meet biological goals and objectives for burrowing owl occupied nesting and overwintering habitat in the permit area will be selected using the reserve design principles described in Chapter 5. Lands acquired and/or managed for burrowing owl nesting habitat will also meet the following criteria.

## Location Criteria

When identifying and acquiring the 600 acres for permanent protection and enrollment into the Reserve System, the Implementing Entity will use the following guidelines.

1. The Implementing Entity will preferentially select a parcel that is inside of the Habitat Plan study area over a parcel that is inside of the expanded study area for burrowing owl conservation.
2. The Implementing Entity will preferentially select parcels that are closer (i.e., within 0.5 mile) to documented nest locations over those that are farther away.
3. Parcels that do not meet criteria 2 (above) may be considered on a case-by-case basis to allow the Implementing Entity to take advantage of opportunities that better fit the conservation strategy<sup>32</sup>.

## Habitat Criteria

The 600 acres of occupied nesting habitat acquired for the Reserve System must have the following:

1. Documented nesting burrowing owls on the parcel in at least one of the previous 3 years. Parcels that are currently occupied should be selected first, followed by parcels that have been occupied in the previous 3 three years.
2. Be surrounded by at least 140 acres of foraging habitat within 0.5 mile of a nest site (including the parcel where nesting was documented). If there is no potential for foraging habitat to be protected through future acquisition, conservation easement, or management agreement, the nest site should not be

---

<sup>32</sup> It is not the intent of the burrowing owl conservation strategy to permanently protect or permanently manage lands in urban areas that are anticipated to be developed (e.g., the North First Street area of San José).

acquired unless long-term viability of the site can be in some other way demonstrated.

3. Currently supports ground squirrels or is located adjacent to another parcel with ground squirrels.
4. Currently support grassland, barren, or other land cover types that can be managed or modified to enhance the site to increase the habitat quality for burrowing owls.

## Management Techniques and Tools

The general principles for grassland management will be followed in all grassland or barren areas (Section 5.3.3, *Grassland Conservation and Management*). Management techniques may include any or all of those outlined in Section 5.3.3 *Grassland Conservation and Management*, and those that will be most beneficial to burrowing owls are grazing and mowing. See **Appendix M** for more details on management techniques and tools for western burrowing owl.

## Uncertainties and Threats

Urbanization has been a threat to western burrowing owls in the South Bay Area for many years and as suitable habitat is developed that threat remains. All of the remaining nesting locations are very near urban development and are located on vacant lands that either have a high potential to be developed in the future, or are managed for purposes other than burrowing owl (e.g., airports). As such, nesting habitat will be subject to many threats typically associated with urban areas, feral cats, pets, commensally wildlife (e.g., skunks, raccoons), and disturbance from humans. Because many of the conservation actions will occur in proximity to urban areas, these threats will continue.

Because population numbers are so low and the number of nesting locations is less than 10, the PVA in this Plan (**Appendix N**) has demonstrated that there is considerable danger of the local population going extinct. While the conservation strategy is designed to reverse this trend, there is uncertainty in its likelihood of success. The success of the strategy is contingent on the remaining colonies being viable over the long term through protection and improved management. This strategy must also be implemented over a shorter time period than for other covered species in order to be successful. This time constraint creates additional uncertainty.

## 5.4.7 Least Bell's Vireo

### Biological Goals and Objectives

The Implementing Entity will work to facilitate the expansion of breeding least Bell's vireos into the study area and increase reproductive success of the bird. This will be done by acquiring and restoring riparian woodland and forest with an open canopy and understory of willows. Acquisition, enhancement, and restoration conservation actions identified for riparian forest and scrub (see Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management*) will benefit least Bell's vireo through breeding and foraging habitat conservation and management.

### Habitat Acquisition, Restoration, and Enhancement

There are 3,097 acres of primary least Bell's vireo modeled habitat in the study area. A total of 330 acres (11%) of modeled habitat are located on Type 1, 2, or 3 open space with 65 acres (2%) permanently protected as Type 1 open space. The Plan proposes to acquire a minimum of 460 acres of least Bell's vireo primary modeled habitat (as described in **Appendix D**) for the Reserve System (**Table 5-17**). In addition, 2 acres of primary modeled habitat will be added to the Reserve System from existing open space. These acquisitions and additions will increase the proportion of protected modeled habitat in the study area to about 17% in Type 1 open space and 26% in Type 1, 2, or 3 open space (**Table 5-17**).

Least bell's vireo primary modeled habitat is defined as willow and mixed riparian forest and scrub, including California sycamore alluvial woodland, in the Uvas, Llagas, Pacheco, and Pajaro watersheds in south Santa Clara County (see **Appendix D**). Riparian land cover types preserved in these watersheds will meet the commitment to acquire 460 acres of least Bell's vireo modeled habitat (**Table 5-17**). Least Bell's vireo acquisition will focus on specific areas within each designated watershed based on historic occurrence information and known range.

In the Pacheco watershed protection will be focused along Pacheco Creek, including the confluence of Little Pacheco Creek and Pacheco Creek. Acquisitions and easements along Uvas Creek will be focused above Uvas Reservoir and intermittently along the creek as it flows southeast to the Pajaro River. Acquisition along lower Uvas-Carnadero Creek will benefit the least Bell's vireo. The only nesting occurrence of least Bell's vireo in Santa Clara County in the last 40-years was along lower Llagas Creek.

The Implementing Entity will focus first on protection of riparian corridors that either have existing nesting habitat for the least Bell's vireo or have the potential to be restored to a riparian condition in the short term. Specific areas of acquisition commitments are listed below.

- 1.6-mile extension of the Uvas Creek Park Preserve upstream to the Hecker Pass Highway (LAND-R1).
- 2.0 miles along the main stem of Pacheco Creek that are in Santa Clara County between Pacheco Lake and San Felipe Lake (LAND-R1).

Additional protection and restoration of riparian corridors in south County watersheds are expected to benefit least Bell's vireo. Similarly, protection and restoration of riparian woodland on Coyote Creek may also benefit least Bell's vireo if that species expands its range to the north into the Coyote Creek watershed. Riparian restoration planned on Coyote Creek under the proposed Three Creeks HCP is likely to count towards Habitat Plan requirements and has potential to benefit this species.

In addition to habitat acquisition into the Reserve System, the Implementing Entity will also restore or create a minimum of 50 acres of willow riparian forest and scrub or mixed riparian forest and woodland to contribute to natural community recovery (**Table 5-12**). If all allowable impacts occur, the Implementing Entity would restore these land cover types at a ratio of 1:1 (an additional 289 acres), for a maximum of 339 acres of restoration or creation. Most of this restoration would occur in south Santa Clara County due to the greater restoration opportunities there. Therefore, most of the 50–289 acres of riparian restoration would create additional foraging and nesting habitat for least Bell's vireo.

## Management Techniques and Tools

Several riparian restoration and enhancement techniques will increase the amount and quality of nesting and foraging habitat for least Bell's vireo. In general, returning riverine systems to a more natural condition (i.e., flow and function) will maintain an array of successional stages for riparian vegetation in associated riparian corridors. This in turn will increase the total acreage of nesting habitat available for least Bell's vireo at any given time. In many cases these restoration efforts will constitute replacing concrete channels, to restore geomorphic and ecological functions to stream reaches that currently do not provide those functions (STREAM-4). Channels that are not necessarily concrete but that are similarly confined will also be replaced, to restore floodplain benches and commensurate functions within stream reaches that currently do not provide those functions (STREAM-5). Specific stream and riparian conservation and management goals, objectives, and actions are discussed above (Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management*), but they are reiterated below.

In order to provide structural heterogeneity the Implementing Entity will plant and/or seed in native understory and overstory riparian vegetation in riparian restoration sites (STREAM-2). In most cases planting or seeding will occur in existing gaps in native riparian vegetation to promote continuity of riparian corridors (STREAM-3). This will ensure that there are various successional stages along these corridors, rather than a corridor that is dominated by mature

trees. In a natural setting vegetation succession is controlled by natural events like scouring floods and fires. Absent those events, succession is not interrupted and mature trees dominate the community while early successional vegetation is lost. Without early successional vegetation in a riparian community, species like the least Bell's vireo will not occur. In order to retain some level of all successional stages of vegetation within a riparian community, activities that mimic natural physical processes, such as girdling trees, will be implemented to encourage early successional vegetation to grow (STREAM-5).

A brown-headed cowbird management program will be implemented if least Bell's vireos become regular nesters in the study area (>3 nests over at least two consecutive years) and brown-headed cowbird eggs are discovered in vireo nests (STREAM-7). The monitoring and management program will be implemented consistent with guidelines of the North American Cowbird Advisory Council, or the best scientific information available at the time, and with oversight from CDFG and USFWS. If other predators are shown to adversely affect the nest success of vireo's (e.g., feral cats, raccoons, skunks), additional predator control may be necessary (LM-13). If monitoring shows that cowbirds are not reducing the nest success of vireos then the cowbird management program will be terminated.

## Uncertainties and Threats

An ongoing threat to songbird breeding success is the brown-headed cowbird. This brood parasite reduces the total number of young produced per breeding songbird pair and lowers the overall success rate for the population. Attempts to control brown-headed cowbirds through trapping or shooting have shown short-term benefits to riparian songbird species, including the Bell's vireo. Implementation of a brown-headed cowbird control program was discussed above.

### 5.4.8 Tricolored Blackbird

#### Biological Goals and Objectives

The Implementing Entity will work to increase the population size of tricolored blackbird in the study area. This will be accomplished by protecting at least four sites that support, historically supported, or could support tricolored blackbird colonies. Each protected site will have at least 2 acres of breeding (marsh) habitat and will have at least 200 acres of foraging habitat within 2 miles. These breeding sites will either be enhanced or restored breeding habitat in historically/currently occupied areas within the Reserve System or newly created ponds suitable for breeding tricolored blackbirds. Acquisition, enhancement, and restoration/creation conservation actions identified for grasslands (see Section 5.3.3 *Grassland Conservation and Management*), valley oak woodlands (see Section 5.3.5 *Oak and Conifer Woodland Conservation and Management*), riparian forest and scrub (see Section 5.3.6 *Riverine and Riparian Forest and*

*Scrub Conservation and Management*), and wetlands and ponds (see Section 5.3.7 *Wetland and Pond Conservation and Management*) will benefit tricolored blackbird through breeding, foraging, and year-round habitat conservation and management.

## Acquisition, Restoration, and Creation

There are 140,291 acres of tricolored blackbird modeled habitat within the study area. A total of 29,435 acres (21%) of that habitat are located in Type 1, 2, or 3 open space with 11,037 acres (8%) permanently protected as Type 1 open space. The Plan proposes to acquire a minimum of 19,000 acres of modeled primary and secondary habitat for the Reserve System. In addition, 3,840 acres of modeled primary and secondary habitat will be added to the Reserve System from existing open space. These acquisitions and additions will increase the proportion of modeled habitat in the study area to about 24% in Type 1 open space and 35% Type 1, 2, or 3 open space (**Table 5-17**).

As part of the preservation acreages above, the Implementing Entity will acquire 5 acres of modeled breeding habitat within dry land farming or ranching complexes in Coyote Valley and the Diablo Hills (LAND-WP8). A high priority will be given to currently occupied sites or sites that have been occupied since 1997. Additional preference will be given to historic breeding sites that could be restored. Land acquisition to benefit tricolored blackbird will occur in the areas between Henry W. Coe State Park and San Felipe Lake in San Benito County. Historically San Benito Lake has supported nesting tricolored blackbirds so protection of modeled breeding and foraging habitat near there will benefit the species over the long term. Additional protection in the Pescadero and Tar Creek watersheds southwest of Gilroy will simultaneously protect modeled nesting habitat and adjacent foraging habitat near two historic occurrences. There are also areas that will be protected along the Pacheco Creek corridor where there is modeled breeding habitat surrounded by agricultural lands or annual grasslands, which provide the necessary breeding and foraging habitat combination. Additional modeled habitat will be preserved, enhanced, and monitored west and south of Chesbro Reservoir.

In order to ensure adequate breeding and foraging habitat is available for future breeding colonies the Implementing Entity will offer financial incentives to private landowners to enhance pond and marsh habitat to suit breeding tricolored blackbirds and to modify farming or ranching techniques to ensure that dry-land farming and ranching activities are executed in a way that is compatible with nesting and foraging tricolored blackbirds (POND-14, POND-15). The Implementing Entity will help landowners apply for existing grants (e.g., North American Wetlands Conservation Act Small Grants Program [USFWS], or Environmental Quality Incentives Program of the Farm Bill [USDA Natural Resources Conservation Service]) as well as provide supplemental funds in the event that grants are unsuccessful. In addition, the Implementing Entity will ensure that there is at least 200 acres of permanently protected modeled foraging habitat within 2-miles of tricolored blackbird breeding sites protected under the Plan (LAND-WP9). If there is not adequate modeled foraging habitat available

in existing Type 1 open space within 2 miles of breeding sites protected under the Plan, the difference in acreage, up to 200 acres per breeding site, will be protected through acquisition or easement within 2 miles of each breeding site.

In addition to protecting new breeding habitat the Implementing Entity will also restore freshwater marsh that will support dense reed-like vegetation (cattails) or other native vegetation (nettles) that will attract nesting tricolored blackbirds (POND-16). Each of these areas will include at least 2 acres of breeding habitat surrounded by sufficient foraging habitat. Of the 20 acres of newly created ponds within the permit area (POND-10), and the estimated 52 acres of ponds to mitigate for the loss of ponds to covered activities, those surrounded by suitable tricolored blackbird foraging habitat will be managed to support dense-reed like vegetation adequate for tricolored blackbird nesting.

In areas with nonnative vegetation (e.g., Himalayan blackberry) that supports existing tricolored blackbird colonies, the Implementing Entity will initiate a gradual (3–4-year) transition from nonnative vegetation to native vegetation that is structurally similar (POND-17). This would only be implemented if the USFWS and CDFG determined that the colony was large enough and stable enough to accommodate the change. In most cases the vegetation would not be altered unless the colony was abandoned for at least three breeding seasons. In riparian areas, constrained channels will be replaced with more natural channels to restore geomorphic and ecological functions to stream reaches that currently do not provide those functions (STREAM-4). This will ensure that a variety of successional stages are supported within riparian corridors, including side channels and benches where slower water supports marsh-like vegetation.

## Management Techniques and Tools

The management techniques that will be utilized to promote tricolored blackbird nesting colony success are captured above (Section 5.3.7 *Wetland and Pond Conservation and Management*). Those management techniques include:

- Planting of native emergent vegetation.
- Fencing off portions of ponds or wetlands to reduce grazing pressure and exclude feral pig activity.
- Implementation or continuation of a grazing program in potential foraging habitat within 2-miles of known breeding colonies.

## Uncertainties and Threats

Tricolored blackbird colonies are an ephemeral resource. Nest colonies can persist for many years in the same location or sites can be occupied irregularly over time. In order to control for this uncertainty when attempting to protect or reestablish nesting colonies it is important to concentrate protection and management efforts in areas that either support or have some documentation of

historical breeding colonies. It is highly likely that breeding habitat can be protected, restored, or created and breeding blackbirds will never occupy it.

## 5.4.9 San Joaquin Kit Fox

### Biological Goals and Objectives

The Implementing Entity will work to increase the ability of San Joaquin kit fox to move within and through the study area and increase the likelihood of breeding. Because the study area is outside the three San Joaquin kit fox core areas,<sup>33</sup> land acquisition and habitat enhancement focuses on building connections between the more isolated satellite populations in order to contribute to the *Level A Strategy* to “work toward the establishment of a viable complex of kit fox populations (i.e., a viable metapopulation) on private and public lands throughout its geographic range”, as identified in *Recovery Plan for Upland Species of the San Joaquin Valley* (U.S. Fish and Wildlife Service 1998a). In addition, the Plan supports the *Habitat Protection and Population Interchange Recovery Action xiv* to “Protect existing kit fox habitat in the northern, northeastern, and northwestern segments of their geographic range...” (U.S. Fish and Wildlife Service 1998a).

This will be accomplished by protecting land through fee title purchase or easement and managing those lands as part of the Reserve System. Protection will be focused in areas with land cover types such as annual grasslands and oak woodlands, where this species has the highest potential to occur (see **Appendix D**). In accordance with the *Level A Strategy*, these protected areas will have a diversity of soils types, topography, aspect, and other environmental gradients to account for movement, foraging, and resting habitat (U.S. Fish and Wildlife Service 1998a). The Reserve System will benefit San Joaquin kit fox in the Pacheco Creek watershed in the uplands between Pacheco State Park and the Romero Ranch in the southeastern corner of the study area. Additional Reserve lands will be acquired between Henry W. Coe State Park and San Felipe Lake that will also benefit the species. The Reserve System will help to ensure that if San Joaquin kit fox are able to cross SR 152 that they will be able to fully utilize the lowland hills of the Diablo Range. In line with in the *Population Ecology and Management Recovery Action*, the Implementing Entity will enhance grassland and oak woodland habitat within the Reserve System to support a more abundant prey base (i.e., California ground squirrels) for San Joaquin kit fox (U.S. Fish and Wildlife Service 1998a).

Outside of the Reserve System the Plan will also contribute to the *Level A Strategy* goal on private land (U.S. Fish and Wildlife Service 1998a). The Implementing Entity will work to influence land-uses that are compatible with kit fox movement. Most importantly the Implementing Entity will identify

<sup>33</sup> As identified by the *Recovery Plan for Upland Species of the San Joaquin Valley*, there are three identified core populations of San Joaquin kit fox: Carrizo Plain Natural Area, Natural lands of western Kern County, and Fresno and eastern San Benito Counties (U.S. Fish and Wildlife Service 1998a).

important habitat linkages across SR 152, between the SR 152/156 interchange and the Santa Clara/Merced County line. Working with road operators (VTA and Caltrans), the Implementing Entity will improve passage along this highway when future road improvements are designed and implemented. Improvements will include removal or “perforation” of sections of median barriers along roadways to improve successful wildlife crossings and, if biologically appropriate, installation of fencing or other features to direct wildlife to those open sections (LM-5).

Acquisition, enhancement, and restoration of grasslands (see Section 5.3.3 *Grassland Conservation and Management*), oak woodlands (see Section 5.3.5 *Oak and Conifer Woodland Conservation and Management*), riparian forest and scrub (see Section 5.3.6 *Riverine and Riparian Forest and Scrub Conservation and Management*), and seasonal wetlands (see Section 5.3.7 *Wetland and Pond Conservation and Management*) in the southern portion of the County are expected benefit to San Joaquin kit fox through foraging and movement habitat conservation and management.

## Acquisition and Enhancement

There are 40,892 acres of modeled San Joaquin kit fox habitat (includes secondary and low-use secondary habitat) within the study area. Although not modeled, some of this habitat may also be potential breeding habitat. A total of 6,315 acres (15%) of modeled habitat are located in Type 1, 2, or 3 open space with 5,067 acres (12%) permanently protected as Type 1 open space. The Plan proposes to add a minimum of 4,100 acres of modeled habitat to the Reserve System, increasing the proportion of protected modeled habitat in the study area to about 22% as Type 1 open space and 25% as Type 1, 2, or 3 open space (**Table 5-17**).

As stated above, land acquisition and habitat enhancement will contribute to species recovery by building connections among the satellite populations in the northern part of the species’ range (U.S. Fish and Wildlife Service 1998a). The Implementing Entity will protect through fee title acquisition or easements annual grassland and associated oak woodland land cover types (e.g., oak savanna and oak woodland within 500 feet of annual grassland) north and south of SR 152, east of the SR 152/156 interchange (LAND-G9).

This portion of the study area has the highest potential to support San Joaquin kit fox, though SR 152 is a considerable barrier across the landscape. Land acquisition along Pacheco Creek would benefit kit fox by preserving likely movement routes, foraging habitat, and possible (although unlikely) den sites (i.e., breeding sites). Specific areas where enhancement could occur to increase the permeability of SR 152 include the undercrossing where Little Pacheco Creek flows into Pacheco Creek and several other small drainages that flow under the roadway before connecting with Pacheco Creek on the south side of the road (**Figure 5-7b**). This will ensure that if costly enhancements are made to roadway infrastructure to create better connections for this species, that the natural lands on either side of the roadway will also remain high quality habitat in perpetuity.
