and a rapid invasion of annual grasses eliminated what had once been quality habitat, leading to the. The population is just barely hanging on; in each year from 2006–2008 one individual checkerspot butterfly was observed.

Management activities on the southern parcel Tulare Hill are now being done as mitigation for NO<sub>x</sub> and NH<sub>3</sub> emissions from the Metcalf Energy Center, and have maintained high habitat quality. A Safe Harbor Agreement with The Pacific Gas and Electric Company was developed from 2004 through 2008, and cattle were introduced into the northern 230+ acres that had been ungrazed since 2001. Recovery of hostplant and nectar sources is expected over the next 5–10 years depending on restoration efforts.

### Other Habitat Areas

No systematic surveys of other serpentine patches west of the Coyote Valley were done from 2004 through 2008. It is likely that several of the larger patches (Hale Ave, the Kalana's) support small populations. Butterflies were observed in Rancho Canada del Oro in recent years.

Habitat conditions in the Santa Teresa Hills, especially in the County Park, continue to deteriorate as grass invasions continue in areas with no grazing. No systematic surveys for adult butterflies have been done. Grazed areas in the southeast portions of the Santa Teresa Hills (owned by IBM) continue to support high densities of *Plantago erecta* and nectar sources.

## Existing Conservation Actions in the Study Area

The U.S. Fish and Wildlife Service published a recovery plan for serpentine plants and animals of the San Francisco Bay area in 1998, which includes the Bay checkerspot butterfly. The primary recovery tasks identified for the butterfly are protection of existing habitats, along with their habitat restoration and management, plus population monitoring and further research.

Fifteen units of critical habitat for the bay checkerspot butterfly were designated by the U.S. Fish and Wildlife Service in 2008. The designated critical habitat includes 1,692 acres in San Mateo County and 16,601 acres in Santa Clara County.

At least two HCPs have been approved that provide an incidental take permit for the Bay checkerspot. The San Bruno Mountain HCP, approved in 1982 as the first HCP in the country, includes the bay checkerspot. However, because the butterfly has not been observed on San Bruno Mountain since the mid-1980s, the permit had no provision for incidental take of the butterfly, so no permit was issued for the species. The Bay Checkerspot butterfly may be added as a covered species under an amendment to the San Bruno Mountain HCP, which is currently in development. Two HCP's were prepared by The Pacific Gas and Electric Company for the Metcalf-Edenvale reconductoring project in San José and the

related Metcalf-Hicks/Vasona Line Extension from San José to Los Gatos. The Metcalf-Edenvale HCP had a three year permit term, which expired in 2001. There are at least two other agreements related to HCP's that are currently in development in the Coyote Hills.

Other agreements have led to the establishment of two preserves for the bay checkerspot butterfly. In 1986, USFWS entered into a conservation agreement with Waste Management of California, Inc. and the City of San José to protect 267 acres of habitat for a 15-year period at the Kirby Canyon Landfill in San José (Murphy 1988). In 1991, a housing and golf course project in the Silver Creek Hills of San José resulted in the perpetual protection of a 115-acre conservation area. Since 1991, additional land has also been set aside for numerous projects as mitigation for impacts to Bay checkerspot butterfly, including the Metcalf Energy Center Ecological Preserve on Tulare Hill and their Coyote Ridge parcel (131 acres total), and a parcel acquired by VTA in 2006 on Coyote Ridge for mitigation for recent highway widening projects.

Active research and monitoring on the Bay checkerspot continues by several workers affiliated with Stanford University, other institutions, and consulting firms is ongoing.

## Modeled Habitat Distribution in Study Area

The serpentine habitats where this species reproduces are easily identified in the study area. Due to the extensive research on the population dynamics of this species most of these areas have been surveyed, some quite extensively. Other areas have been surveyed in a more cursory fashion merely to determine whether the species is present or not and to assess the available habitat. The suitable habitat known or expected to occur in the study area is shown in Figure 1. This map was developed using an iterative process of refinement with two experts in Bay checkerspot butterfly biology, Dr. Stuart Weiss and Dr. Alan Launer. Maps were first developed showing patches of serpentine bunchgrass grassland as mapped by the Habitat Plan (see Chapter 3 for a description of the mapping methods). These patches of serpentine grassland, referred to as "habitat units", were further refined in consultation with the experts to delineate populations of Bay checkerspot butterfly based on field research and observations.

Bay checkerspot butterfly habitat units are divided into two broad categories: core and satellite. The definitions for core and satellite habitat units are adapted from the *Recovery Plan for Serpentine Soil Species of the San Francisco Bay Area* (U.S. Fish and Wildlife Service 1998). Core habitat units are "moderate to large areas of suitable habitat that support persistent bay checkerspot populations." Satellite habitat units are "generally smaller and contain less high-quality habitat than core areas, and may occur some distance from core areas."

The Habitat Plan identified eight core habitat units found within the four "core areas" defined by the Recovery Plan. The Habitat Plan also identified 13 satellite

habitat units. The status of each core and satellite habitat units is classified as “occupied” or “historic/unoccupied”. For habitat units defined as “occupied,” species is known to occupy the patch at least in some years. Where individuals were present historically, but now the site is unoccupied and likely no longer suitable, the habitat unit is defined as “historic/unoccupied”. Additional areas that support serpentine bunchgrass grassland (as mapped by the HCP/NCCP) and are adjacent to known populations or are within the known dispersal distance for the adults in these populations were also delineated as either suitable but “occupancy unknown” or suitable and “potential (no records)” habitat. If the site had not been surveyed thoroughly or surveyed in the last ten years, a habitat unit was classified as “occupancy unknown”. Otherwise suitable patches of serpentine grassland within the dispersal distance of known populations were considered “potential (no records)” habitat units if land use management practices such as livestock grazing could improve conditions for the species. The habitat units are described further and the categories are explained in Table 4.

**Table 4.** Bay Checkerspot Butterfly Habitat Units in the Study Area

Habitat Unit <sup>1</sup> (from North to South)	Status in 2006 <sup>2</sup>	Size (acres)
<i>Target Areas</i>		
UTC	Occupied	1,607
Kirby/East Hills	Occupied	1,334
Pigeon Point	Occupied	117
Silver Creek Hills (Central)	Occupied	208
Metcalf North Ridge <sup>3</sup>	Occupied	518
Metcalf	Occupied	629
Hale/Falcon Crest	Occupied	371
Cañada Garcia	Occupied	180
Kalana Avenue (1–4)	Occupied	110
Tulare Hill	Occupied	336
Santa Teresa Hills (Main)	Occupied	936
Santa Teresa Hills (North)	Potential (no records)	190
Coyote-Bear Ranch County Park	Occupied	60
Calero	Occupied	359
Subtotal Target Areas		6,955
<i>Non-Target Areas</i>		
Silver Creek Hills North #1	Occupied	382
Silver Creek Hills North #2	Potential (no records)	406
Pound Site	Occupied	216
Communications Hill 1	Historic/Unoccupied	230
Communications Hill 2	Historic/Unoccupied	25
San Martin/Hayes Valley	Occupancy Unknown	201
Southwest Anderson Reservoir	Occupancy Unknown	189
Valley Christian High School	Historic/Unoccupied	15
Subtotal Non-Target Areas		1,665
<b>Grand Total</b>		<b>8,621</b>

## Notes:

<sup>1</sup> Habitat Unit names are based on labels used by researchers at Stanford University for long-term monitoring and ecological studies. Also see Figure 1.

<sup>2</sup> Historic/Unoccupied = Site formally occupied but now extirpated and no longer suitable; Occupied = Site remains suitable and Bay checkerspot butterflies observed in at least a portion of the site in some years (not occupied every year); Potential (no records) = Site contains habitat that could be made suitable with proper management (currently unoccupied); Occupancy Unknown = Site status unknown due to lack of field surveys.

<sup>3</sup> Metcalf North Ridge is also referred to as “San Felipe”

## California Tiger Salamander (*Ambystoma californiense*)

### Legal Status

**State:** Threatened<sup>1</sup>

**Federal:** Central California population listed as Threatened (U.S. Fish and Wildlife Service 2004); Sonoma County and Santa Barbara County populations listed as Endangered (U.S. Fish and Wildlife Service 2000, 2003)<sup>2</sup>

**Critical Habitat:** Designated for the central California population only on August 23, 2005 (U.S. Fish and Wildlife Service 2005a)

**Recovery Planning:** None for central California population. A recovery strategy has been developed for the Sonoma County population (U.S. Fish and Wildlife Service 2005b)

### Taxonomy

Formerly regarded as a subspecies of *A. tigrinum*, the California tiger salamander (*Ambystoma californiense*) was first described by Gray in 1853 based on specimens that had been collected in Monterey, California. Based on recent studies of the genetics, geographic distribution, and ecological differences among the members of *A. tigrinum* complex, the California tiger salamander has been determined to represent a distinct species (U.S. Fish and Wildlife Service 2004).

The biogeographical and genetic information supporting the recognition of the Santa Barbara County and Sonoma County populations as distinct population segments under the federal Endangered Species Act are reviewed in those listing decisions (U.S. Fish and Wildlife Service 2000, 2003). More information on the taxonomic status and a description of the species' physical characteristics can be found in the listing decision for the central California population (U.S. Fish and Wildlife Service 2004).

<sup>1</sup> The California Fish and Game Commission determined that the California tiger salamander should be listed as threatened on May 20, 2010. This determination still needs to be finalized by the State Office of Administrative Law. The state listing applies to the entire range of this species.

<sup>2</sup> The 2004 listing of the central California population of the California tiger salamander (U.S. Fish and Wildlife Service 2004a) also downgraded the Sonoma County and Santa Barbara County populations of the species from endangered to threatened. However, an August 19, 2005 ruling from U.S. District Judge William Alsup vacated this downlisting, so these populations remain listed as endangered.

## Distribution

### General

The California tiger salamander is endemic to California. Historically, the California tiger salamander probably occurred in grassland habitats throughout much of the state. Although this species still occurs within much of its range, it has been extirpated from many areas it once occupied (Fisher and Shaffer 1996; Stebbins 1985). The loss of California tiger salamander populations has been due primarily to habitat loss within their historic range (Fisher and Shaffer 1996) (Figure 1).

Based on genetic analysis, there are six populations of California tiger salamanders, distributed as follows: (1) Santa Rosa area of Sonoma County, (2) Bay Area (central and southern Alameda, Santa Clara, western Stanislaus, western Merced, and the majority of San Benito counties), (3) Central Valley (Yolo, Sacramento, Solano, eastern Contra Costa, northeast Alameda, San Joaquin, Stanislaus, Merced, and northwestern Madera counties), (4) southern San Joaquin Valley (portions of Madera, central Fresno, and northern Tulare and Kings counties), (5) Central Coast range (southern Santa Cruz, Monterey, northern San Luis Obispo, and portions of western San Benito, Fresno, and Kern counties), and (6) Santa Barbara County (Shaffer and Trenham 2005).

Most populations occur at elevations below 1,500 feet, but California tiger salamanders have been recorded at elevations up to 3,660 feet, just below Rose Peak in the Ohlone Regional Wilderness, Alameda County (California Department of Fish and Game 2010). Although populations have declined, the species continues to breed at a large number of locations within its current range (59 FR § 18353–18354, April 18, 1994). At most historic breeding sites below 200 feet elevation, ponds remain present but no longer support California tiger salamanders. These sites are typically occupied by nonnative species (Fisher and Shaffer 1996).

## Occurrences within the Study Area

### Historical

There are records from throughout the study area from 1895 to 1990 (California Natural Diversity Database 2006). California tiger salamanders are thought extirpated from at least eight historical breeding areas (California Natural Diversity Database 2006). The eight extirpated sites all occur along the valley floor in the study area and follow the Highway 101 corridor. The extirpation of the species from these areas is likely due to habitat lost to development.

## Recent

There are approximately 100 occurrence records from 1990 through 2005 in the study area (California Natural Diversity Database 2006; T. Marker pers. comm.). The occurrences are scattered throughout the study area and on both sides of the valley, with large clusters of occurrences in Henry W. Coe State Park and Joseph D. Grant County Park. See Figure 2 for all recent occurrences.

## Natural History

### Habitat Requirements

California tiger salamanders require two major habitat components: aquatic breeding sites and terrestrial aestivation or refuge sites. California tiger salamanders inhabit valley and foothill grasslands and the grassy understory of open woodlands, usually within one mile of water (Jennings and Hayes 1994). Following metamorphosis California tiger salamanders are terrestrial animals which spend most of their time underground in subterranean refuge sites, or *refugia*. Underground retreats are usually California ground squirrel (*Spermophilus beechyii*) or pocket gopher (*Thomomys bottae*) burrows and, occasionally, human-made structures. Adults emerge from underground to breed, but only for brief periods during the year. California tiger salamanders breed and lay their eggs primarily in vernal pools and other ephemeral ponds that fill in winter and often dry out by summer (Loredo et al. 1996); they sometimes use permanent human-made ponds (e.g., stock ponds), reservoirs, and small lakes that do not support predatory fish or bullfrogs (see *Ecological Relationships* discussion below) (Stebbins 1972; Zeiner et al. 1988). Streams are rarely used for reproduction.

Adult salamanders migrate from upland habitats to aquatic breeding sites during the first major rainfall events of fall and early winter and return to upland habitats after breeding. This species requires small-mammal burrows for cover during the non-breeding season and during migration to and from aquatic breeding sites (Zeiner et al. 1988). California tiger salamanders also use logs, piles of lumber, and shrink-swell cracks in the ground for cover (Holland et al. 1990). California tiger salamanders can overwinter in burrows up to one mile from their breeding sites (Jennings and Hayes 1994) and have been documented up to ~1.2 mile (Sweet pers. comm.).

The California tiger salamander is particularly sensitive to the duration of ponding in aquatic breeding sites. Because tiger salamanders have a long developmental period, the longest lasting seasonal ponds or vernal pools are the most suitable type of breeding habitat for this species; these pools are also typically the largest in size (Jennings and Hayes 1994). Because at least 10 weeks are required to complete metamorphosis (see *Demography* below) (Feaver 1971), aquatic sites that are considered suitable for breeding should retain water for a minimum of 10 weeks. Moreover, large vernal pool complexes, rather than isolated pools, probably offer the best quality habitat;

these areas can support a mixture of core breeding sites and nearby refugia (Shaffer et al. 1994; Jennings and Hayes 1994).

California tiger salamanders primarily use California ground squirrel burrows as refuge sites (Loredo et al. 1996; Trenham 2001); Botta's pocket gopher (*Thomomys bottae*) burrows are also frequently used (Barry and Shaffer 1994; Jennings and Hayes 1994). Loredo et al. (1996) emphasized the importance of California ground squirrel burrows as refugia for California tiger salamanders, and suggested that a commensal relationship existed between the California tiger salamander and California ground squirrel, in which tiger salamanders benefit from the burrowing activities of squirrels. In a study conducted near Concord, California, Loredo et al. (1996) found that California ground squirrel burrows were used almost exclusively as refuge sites by California tiger salamanders. Also, tiger salamanders apparently do not avoid burrows occupied by ground squirrels (Loredo et al. 1996).

**Table 1.** Habitat Associations for California Tiger Salamander

Land Cover Type	Land Cover Use	Habitat Designation	Habitat Parameters	Rationale
Herbaceous-dominated	Dispersal, refugia	Dispersal	Tiger salamanders can be found up to 1.3 mile (2.1 km) from wetlands and aquatic habitats, spend majority of lives in burrows in upland habitats	U.S. Fish and Wildlife Service 2004
Wetlands	Breeding, larval development	Breeding	All life stages occur around breeding sites	U.S. Fish and Wildlife Service 2004
Aquatic	Breeding, Larval development	Breeding	All life stages may occur around breeding sites	U.S. Fish and Wildlife Service 2004

## Reproduction

Adult California tiger salamanders migrate to and congregate at aquatic breeding sites during warm rains, primarily between November and February (Shaffer and Fisher 1991; Barry and Shaffer 1994). Tiger salamanders are rarely observed except during this period (Loredo et al. 1996). During the winter rains, tiger salamanders breed and lay eggs primarily in vernal pools and other shallow, ephemeral ponds that fill in winter and often dry by summer (Loredo et al. 1996). This species also uses permanent human-made ponds (without predatory fish) for reproduction. Spawning usually occurs within a few days after migration, and adults probably leave the breeding sites at night soon after spawning (Barry and Shaffer 1994 citing Storer 1925).

Eggs are laid singly or in clumps on both submerged and emergent vegetation and on submerged debris in shallow water. In ponds without vegetation, females lay eggs on objects on the pond bottom (Stebbins 1972; Shaffer and Fisher 1991; Barry and Shaffer 1994; Jennings and Hayes 1994). After breeding, adults leave the breeding ponds and return to their refugia (small mammal burrows, etc.).

After approximately two weeks, the salamander eggs begin to hatch into larvae. Once larvae reach a minimum body size they metamorphose into terrestrial juvenile salamanders. The amount of time that salamanders spend in the larval stage and the size of individuals at the time of metamorphosis seems to be dependent on many factors. Larvae in small ponds develop faster, while larvae in larger ponds that retain water for a longer period are larger at time of metamorphosis. At a minimum, salamanders require ten weeks living in ponded water to complete metamorphosis but in general development is completed in 3–6 months (Petranka 1998). If a pond dries prior to metamorphosis, the larvae will desiccate and die (U.S. Fish and Wildlife Service 2000). Juveniles disperse from aquatic breeding sites to upland habitats after metamorphosis (Storer 1925; Holland et al. 1990).

### Foraging Requirements

Aquatic larvae feed on algae, small crustaceans, and small mosquito larvae for about six weeks after hatching (U.S. Fish and Wildlife Service 2000). Larger larvae feed on zooplankton, amphipods, mollusks, and smaller tadpoles of Pacific treefrogs (*Pseudacris regilla*), California red-legged frogs (*Rana aurora draytoni*), western toads (*Bufo boreas*) and spadefoot toads (*Spea* spp.) (Zeiner et al. 1988; U.S. Fish and Wildlife Service 2000). Adults eat earthworms, snails, insects, fish, and small mammals (Stebbins 1972).

### Movement

The proximity of refuge sites to aquatic breeding sites also affects the suitability of salamander habitat. Adult tiger salamanders have been observed up to 1.3 miles (2.1 km) from breeding ponds (U.S. Fish and Wildlife Service 2004). A recent trapping effort in Contra Costa County captured California tiger salamanders at distances ranging from 2,641 feet to 3,960 feet from the nearest breeding, aquatic site (U.S. Fish and Wildlife Service 2004). In a study in winter 2002–2003, Trenham and Shaffer (2005) found that 95% of tiger salamanders resided within 2040 feet (620 meters) of their breeding pond in Solano County.

Loredo et al. (1996) found that tiger salamanders may use burrows that are first encountered during movements from breeding to upland sites. In their study

area, where the density of California ground squirrel burrows was high, the average migration distances between breeding and refuge sites for adults and juveniles was 118 feet (35.9 meters) and 85 feet (26.0 meters), respectively. Also, habitat complexes that include upland refugia relatively close to breeding sites are considered more suitable because predation risk and physiological stress in California tiger salamanders probably increases with migration distance.

Dispersal of juveniles from natal ponds to underground refugia could occur throughout the year. While juveniles will move short distances from breeding ponds once they start to dry up in the late spring and summer, longer distances from breeding ponds are attained during rainy periods. Juveniles disperse from breeding sites after spending a few hours or days near the pond margin (Jennings and Hayes 1994). Juveniles have been observed to migrate up to 1 mile from breeding pools to upland areas (U.S. Fish and Wildlife Service 2004). Dispersal distance is likely phased and may increase with an increase in precipitation (Trenham 2001).

Some genetic data suggest low rates of California tiger salamander migration between vernal pool complexes (Shaffer et al. 1994; Irschick and Shaffer 1997) or metapopulations; this suggests that natural colonization after a local extirpation event may be unlikely (Fisher and Shaffer 1996). Trenham et al. (2001) showed that pool complexes occupied by California tiger salamander fit a metapopulation model, and dispersal rates between ponds may be high for both first-time and experienced breeders. Dispersal rates are probably high enough to prevent local extirpations within a pool complex.

**Table 3.** Movement Distances for California Tiger Salamander

Type	Distance/Area	Location of Study	Citation
Adult migration	620 meters	Jepson Prairie Preserve	Trenham and Shaffer 2005
	2,641–3,960 feet	Contra Costa County	U.S. Fish and Wildlife Service 2004
	0.9–1.3 mile	Santa Barbara	Sweet pers. comm. 2006
Juvenile migration	630 meters	Jepson Prairie Preserve	Trenham and Shaffer 2005
	700 meters	Monterey County	Trenham et al. 2001

## Ecological Relationships

California tiger salamander larvae and embryos are susceptible to predation by fish (Stebbins 1972; Zeiner et al. 1988; Shaffer et al. 1994), and tiger salamander larvae are rarely found in aquatic sites that support predatory fish (Shaffer and Fisher 1991; Shaffer and Stanley 1992; Shaffer et al. 1994). Aquatic larvae are taken by herons and egrets and possibly garter snakes (Zeiner et al. 1988). Shaffer et al. (1993) also found a negative correlation between the occurrence of California tiger salamanders and the presence of bullfrogs; however, this relationship was detected only in unvegetated ponds. This suggests that vegetation structure in aquatic breeding sites may be important for survival.

Because of their secretive behavior and limited periods above ground, adult California tiger salamanders have few predators (U.S. Fish and Wildlife Service 2000).

## Population Status and Trends

**Global:** *Declining* (NatureServe 2006) (Endemic to California)

**State:** Declining

**Within Study Area:** Unknown

## Threats

California tiger salamander populations have experienced dramatic declines throughout the historical range of the species, particularly in the Central Valley. California tiger salamander populations have declined as a result of two primary factors: widespread habitat loss and habitat fragmentation. These factors have both been caused by conversion of valley and foothill grassland and oak woodland habitats to agricultural and urban development (Stebbins 1985). For example, residential development and land use changes in the California tiger salamander's range have removed or fragmented vernal pool complexes, eliminated refuge sites adjacent to breeding areas, and reduced habitat suitability for the species over much of the Central Valley (Barry and Shaffer 1994; Jennings and Hayes 1994). Grading activities have probably also eliminated large numbers of salamanders directly (Barry and Shaffer 1994). Overall, approximately 75% of habitat for California tiger salamander within its historic range has been lost (Fisher and Shaffer 1996).

The introduction of bullfrogs, Louisiana red swamp crayfish, and nonnative fishes (mosquitofish, bass, and sunfish) into aquatic habitats has also contributed to declines in tiger salamander populations (Jennings and Hayes 1994; 59 FR § 18353–18354, April 18, 1994, U.S. Fish and Wildlife Service 2000). These nonnative species prey on tiger salamander larvae and may eliminate larval populations from breeding sites (Jennings and Hayes 1994). At sites where aquatic vegetation is present, predation by exotic fish appears more likely to result in California tiger salamander extirpation than bullfrogs (Fisher and Shaffer 1996). At most historic breeding sites below 200 feet elevation, ponds remain present but no longer support California tiger salamanders. Instead, these sites are typically occupied by nonnative species (Fisher and Shaffer 1996).

Burrowing-mammal control programs are considered a threat to California tiger salamander populations. Rodent control through destruction of burrows and release of toxic chemicals into burrows can cause direct mortality to individual salamanders and may result in a decrease of available suitable habitat (U.S. Fish and Wildlife Service 2000).

Vehicular-related mortality is an important threat to California tiger salamander populations (Barry and Shaffer 1994; Jennings and Hayes 1994). California tiger salamanders readily attempt to cross roads during migration, and roads that

sustain heavy vehicle traffic or barriers that impede seasonal migrations may have impacted tiger salamander populations in some areas (Shaffer and Fisher 1991; Shaffer and Stanley 1992; Barry and Shaffer 1994). Therefore, establishing artificial barriers to movement or maintaining roads that support a considerable amount of vehicle traffic in areas that support California tiger salamander populations could severely degrade salamander habitat (see Jennings and Hayes 1994).

Hybridization between California tiger salamander and an introduced congener, *A. tigrinum*, has been documented and may be extensive (Riley et al. 2003). *A. tigrinum* was introduced to California for use as fishing bait; and both taxa co-occur in ponds and vernal pools. Hybridization between native and exotic taxa, due to lack of reproductive isolation, can threaten native taxa by causing genetic swamping and reduced genetic diversity of native populations. In rare species such as California tiger salamander, hybridization can also lead to population extirpation. In a study of tiger salamander hybridization conducted in the Salinas Valley, Riley et al. (2003) found that the degree of genetic mixing between California tiger salamander and *A. tigrinum* depended on breeding habitat type. In artificial ponds, there appeared to be no barriers to gene exchange between California tiger salamander and *A. tigrinum*. However, in vernal pools, significantly fewer hybrid genotypes and more pure parental genotypes were found. These results suggest that the potential for reproductive isolation between the two taxa may be higher in native habitats. See **Appendix K** for more details on hybridization between California tiger salamanders and nonnative salamanders.

## Data Characterization

Because this species is listed under the federal Endangered Species Act it has received much attention within its range, including within the study area. Stock ponds are one of the primary likely sources of breeding habitat within the study area. Most of these stock ponds have not been surveyed for California tiger salamanders use, particularly those in remote parts of the study area. Most of the suitable habitat that is threatened by development or other changes in land use has been adequately surveyed, and the threats to the species within the study area have been accurately identified.

## Existing Conservation Actions in the Study Area

Santa Clara Valley Water District has been conducting ongoing amphibian surveys in several areas in its jurisdiction, including stock ponds in Carnadero Preserve, Palassou Ridge, and Henry W. Coe State Park (D. Padley pers. comm.). The Santa Clara County Open Space Authority conducts pond and wetland restoration on their lands that is designed to benefit California tiger salamander and other species.

## Modeled Habitat Distribution in Study Area

### Model Description

#### Assumptions

##### Breeding and Foraging

Potential breeding habitat within the study area is assumed to be all ponds (excluding percolation ponds), coastal and valley freshwater marshes, natural lakes, and seasonal wetlands within riparian, grassland, oak woodland, and conifer woodland land cover types.

##### Upland Refugia and Dispersal Habitat

Upland habitats that provide subterranean refugia for this species are assumed to be within 1.3 miles of primary habitat in grassland, chaparral and coastal scrub, oak woodland, riparian forest/scrub, riparian forest/woodland wetlands, conifer woodlands, and agricultural areas.

#### Rationale

California tiger salamanders require two major habitat components: aquatic breeding sites and upland or refuge sites. California tiger salamanders inhabit valley and foothill grasslands and the grassy understory of open woodlands, usually within 1.3 miles of water (U.S. Fish and Wildlife Service 2005a). The California tiger salamander is terrestrial as an adult and spends most of its time underground in subterranean refugia. Underground retreats usually consist of ground-squirrel burrows and occasionally human-made structures. Adults emerge from underground to breed, but only for brief periods during the year. Tiger salamanders breed and lay their eggs primarily in vernal pools and other ephemeral ponds that fill in winter and often dry out by summer (Loredo et al. 1996); they sometimes use permanent human-made ponds (e.g., stock ponds), reservoirs, and small lakes that do not support predatory fish or bullfrogs (see *Ecological Relationships* discussion below) (Stebbins 1972; Zeiner et al. 1988). Streams are rarely used for reproduction.

Breeding salamanders migrate from upland habitats to aquatic breeding sites during major rainfall events of fall and early winter and return to upland habitats after breeding. This species requires small-mammal (e.g., California ground squirrel) burrows for cover during the non-breeding season and during migration to and from aquatic breeding sites (Zeiner et al. 1988). California tiger salamanders also use logs, piles of lumber, and shrink-swell cracks in the ground for cover (Holland et al. 1990). California tiger salamanders may occupy burrows up to 1.3 mile from their breeding sites during the non-breeding period (U.S. Fish and Wildlife Service 2005a).

## Model Results

Figure 2 shows the modeled potential habitat for the California tiger salamander within the study area. The model output designates breeding habitat and bases upland and dispersal habitat on known movement distances determined by the best knowledge of the species. Suitable habitat for this species is spread evenly throughout the undeveloped portions of the study area, primarily due to the even distribution of stock ponds and other aquatic habitat.

## California Red-Legged Frog (*Rana draytonii*)

### Legal Status

**State:** Species of Special Concern

**Federal:** Threatened

**Critical Habitat:** Designated April 2006 (U.S. Fish and Wildlife Service 2006); Revised March 2010 (U.S. Fish and Wildlife Service 2010)

**Recovery Planning:** Final Recovery Plan May 2002 (U.S. Fish and Wildlife Service 2002)

**Notes:** Status not anticipated to change during permit period

### Taxonomy

The California red-legged frog and northern red-legged frog (*R. a. aurora*) are considered conspecific subspecies with a broad zone of intergradation (Shaffer et al. 2004). Some red-legged frogs found in the intervening areas (southern Del Norte to northern Marin County along the Coast Range), exhibit intergraded characteristics of both subspecies (Hayes and Krempels 1986 in U.S. Fish and Wildlife Service 2002). The two subspecies, and intergrades of the subspecies, may occur together in Mendocino County (U.S. Fish and Wildlife Service 2002).

Descriptions of the species' physical characteristics can be found in the U.S. Fish and Wildlife Service Recovery Plan (U.S. Fish and Wildlife Service 2002).

### Distribution

#### General

The historical range of the California red-legged frog (*Rana draytonii*) extended along the coast from the vicinity of Point Reyes National Seashore, Marin County, California, and inland from Redding, Shasta County southward to northwestern Baja California, Mexico (Jennings and Hayes 1985; Hayes and Krempels 1986). The current distribution is in isolated patches in the Sierra Nevada, northern Coast, and Santa Monica Mountains (Hogan pers. comm.). It is still common in the San Francisco Bay area and along the central coast. In Southern California the species is believed extirpated from the Santa Rosa Ecological Reserve but persists in the Santa Monica Mountains and in San Fransquito Canyon in Newhall (Hogan pers. comm.) (Figure 1).

## Occurrences within the Study Area

### Historical

The red-legged frog was historically found throughout Santa Clara County. There are a number of historic red-legged frog records within the study area dating from 1904 to 1980 (Padley pers. comm.). The observations are shown in Figure 2 and represent museum and California State University at San José records (1904 through 1983), as well as unpublished California Department of Fish and Game records (no specific dates; observed before 1980).

### Recent

An analysis of known locality records for red-legged frog from Santa Clara County (H.T. Harvey and Associates 1997) concluded that the species has essentially disappeared from the urbanized lowland areas of the county as well as from the brackish marshlands bordering the San Francisco Bay. Extant riparian habitats within this region are largely channelized or contain a wide variety of introduced predatory fishes and bullfrogs (Padley pers. comm.). However, red-legged frogs are still found in the foothill and mountain ranges throughout the county (H.T. Harvey and Associates 1997).

According to the California Natural Diversity Database (CNDDB), 93 occurrences of California red-legged frog have been documented within the study area (California Natural Diversity Database 2006). U.S. Fish and Wildlife Service (2002) reports that adult frogs have been observed in Upper Alameda Creek in the Sunol Regional Wilderness, and in many creeks from this area, south to Henry W. Coe State Park.

Approximately half of the occurrences are in creek and pond habitats in Henry W. Coe State Park (Figure 2). Twenty-four of the occurrences are on private property, while the remaining occurrences are on public properties, including City of San José, Santa Clara Valley Water District, and Santa Clara County properties.

## Natural History

### Habitat Requirements

Within their range, California red-legged frogs occur from sea level to about 5,000 feet above sea level (U.S. Fish and Wildlife Service 2002). Almost all of the documented occurrences of this species, however, are located below 3,500 feet. Breeding sites include a variety of aquatic habitats—larvae, tadpoles, and metamorphs use streams, deep pools, backwaters within streams and creeks, ponds, marshes, sag ponds, dune ponds, and lagoons. Breeding adults are commonly found in deep (more than 2 feet) still or slow-moving water with dense, shrubby riparian or emergent vegetation (Hayes and Jennings 1989).

Adult frogs have also been observed in shallow sections of streams that are not shrouded by riparian vegetation. Generally, streams with high flows and cold temperatures in spring are unsuitable for eggs and tadpoles. Stock ponds are frequently used by this species if the ponds are managed to provide suitable hydroperiod, pond structure, vegetative cover, and control of nonnative predators.

During summer, California red-legged frogs often disperse from their breeding habitat to forage and seek summer habitat if water is not available (U.S. Fish and Wildlife Service 2002). This habitat may include shelter under boulders, rocks, logs, industrial debris, agricultural drains, watering troughs, abandoned sheds, or hayricks. The frogs will also use small mammal burrows, incised streambed channels, or areas with moist leaf litter (Jennings and Hayes 1994; U.S. Fish and Wildlife Service 1996, 2002). However, this summer movement behavior has not been observed in all California red-legged frog populations studied.

California red-legged frogs consume a wide variety of prey. Adult frogs typically feed on aquatic and terrestrial insects, crustaceans, and snails (Stebbins 1985, Hayes and Tennant 1985), as well as worms, fish, tadpoles, smaller frogs (e.g., *Hyla regilla*), and occasionally mice (*Peromyscus* spp.) (U.S. Fish and Wildlife Service 2002). Aquatic larvae are mostly herbivorous algae grazers (Jennings et al. 1992). Feeding generally occurs along the shoreline of ponds or other watercourses and on the water surface. Juveniles appear to forage during both daytime and nighttime, whereas subadults and adults tend to feed more exclusively at night (Hayes and Tennant 1985).

**Table 1.** Habitat Associations for California Red-Legged Frog

Land Cover Type	Land Cover Use	Habitat Designation	Habitat Parameters	Rationale
Herbaceous-dominated	Dispersal, forage, refugia	Secondary, movement	Occur in open grasslands with seeps and springs (within 2 miles of seeps, springs, creeks, ponds, and lakes).	Such water sources are too ephemeral for breeding but may provide foraging and refugia habitat for dispersing frogs (U.S. Fish and Wildlife Service 2005)
Riparian woodland	Dispersal, forage, refugia	Secondary, year-round movement, summer	Frogs can be found up to 100 meters from emergent vegetation, undercut banks, rootballs, or small mammal burrows which all provide shelter.	U.S. Fish and Wildlife Service 2002, 2005
Riparian scrub	Dispersal, forage, refugia	Secondary, year-round movement, summer	Same as for riparian woodland.	U.S. Fish and Wildlife Service 2002, 2005
Wetlands	All life stages	Primary, breeding, refugia	All life stages may occur around breeding sites, or frogs may seek multiple habitats.	U.S. Fish and Wildlife Service 2002, 2005
Aquatic	All life stages	Primary, breeding, refugia	All life stages may occur around breeding sites, or frogs may seek multiple habitats.	U.S. Fish and Wildlife Service 2002, 2005

## Reproduction

California red-legged frogs breed from November through April (Storer 1925; U.S. Fish and Wildlife Service 2002). Males usually appear at the breeding sites 2 to 4 weeks before females. Females are attracted to calling males. Females lay egg masses containing about 2,000 to 5,000 eggs, which hatch in 6 to 14 days, depending on water temperatures (U.S. Fish and Wildlife Service 2002). Those eggs develop into tadpoles in 20–22 days. Larvae metamorphose in 3.5 to 7 months, typically between July and September (Storer 1925; Wright and Wright 1949; U.S. Fish and Wildlife Service 2002). Males usually attain sexual maturity at 2 years of age and females at 3 years of age.

## Movement

California red-legged frogs may move over 2 miles up or down drainages from breeding sites and have been observed using adjacent riparian woodlands up to 100 feet from the water (Rathbun et al. 1993). Dispersing frogs have been recorded to cover distances from 0.25 mile to more than 2 miles without apparent regard to topography, vegetation type, or riparian corridors (Bulger 1998). These dispersal movements are generally straight-line, point-to-point migrations rather than following specific habitat corridors. Dispersal distances are believed to depend on the availability of suitable habitat and prevailing environmental conditions. Generally speaking, red-legged frogs will use the extent of a riparian corridor no matter how narrow or wide it is. The primary features driving the use of this habitat are cool moist soil under shrubs or other vegetation where frogs can find refuge for short periods before returning to the water.

On rainy nights, red-legged frogs may roam away from aquatic sites as much as one mile. Red-legged frogs often move away from the water after their first winter, causing sites where red-legged frogs were easily observed in the summer months to appear devoid of this species. Additionally, red-legged frogs sometimes disperse in response to receding water, which often occurs during the driest time of the year (U.S. Fish and Wildlife Service 2005).

**Table 3.** Movement Distances for California Red-Legged Frog

Type	Distance/Area	Location of Study	Citation
Dispersal/migration	0.25 to 2 miles	Santa Cruz County	Bulger et al. 2003
Dispersal/migration	9 to 48 feet	Ventura County	Rathbun et al. 1993, U.S. Fish and Wildlife Service 2005

Note: Disparity in distances between the two studies is likely a function of riparian corridor width or habitats adjacent to riparian areas.

## Ecological Relationships

California red-legged frogs are primary, secondary, and tertiary consumers in the aquatic/terrestrial food web of their habitat. As described above, they prey on a variety of invertebrates and vertebrates, as well as algae and larvae. Numerous native predators prey on these frogs, including raccoons (*Procyon lotor*), great blue herons (*Ardea herodias*), American bitterns (*Botaurus lentiginosus*), black-crowned night herons (*Nycticorax nycticorax*), red-shouldered hawks (*Buteo lineatus*), opossums (*Didpephis virginiana*), striped skunks (*Mehpitis mephitis*), spotted skunks (*Spilogale pituorius*), and garter snakes (*Thamnophis* spp.) (Fitch 1940; Fox 1952; Jennings and Hayes 1990; Rathbun and Murphy 1996). In some areas, introduced aquatic vertebrates and invertebrates also prey on one or more of the life stages of California red-legged frogs. These predators include bullfrogs (*Rana catesbeiana*), African clawed frogs (*Xenopus laevis*), red swamp crayfish (*Procambarus clarkii*), signal crayfish (*Pacifastacus leniusculus*), bass (*Micropterus* spp.), catfish (*Ictalurus* spp.), sunfish (*Lepomis* spp.), and mosquitofish (*Gambusia affinis*) (Hayes and Jennings 1986).

Adult California red-legged frogs can live 8 to 10 years (Jennings et al. 1992), but the average life span is probably much lower (U.S. Fish and Wildlife Service 2002). Most mortality occurs during the tadpole stage (Licht 1974). No long-term studies have been conducted on the population dynamics of red-legged frogs.

## Population Status and Trends

### Population Trend

**Global:** Declining (NatureServe 2006)

**State:** Declining (Jennings et al. 1992)

**Within Study Area:** Declining (Jennings et al. 1992)

Although population numbers are not precisely known, the U.S. Fish and Wildlife Service estimates that California red-legged frog populations are declining at a rapid rate. A 70% reduction in the geographic range of this subspecies was witnessed in the early to mid-1990s. This decline was primarily a

result of habitat loss and alteration and introduction of exotic predators (U.S. Fish and Wildlife Service 2002).

## Threats

Threats to the species include removal and alteration of habitat due to urbanization, overgrazing of aquatic and riparian habitats, and predation by nonnative species. During a controlled study in 1995, Lawler et al. (1999) found that fewer than 5% of California red-legged frog tadpoles will survive in ponds with bullfrogs present. The viability of California red-legged frog populations is threatened by numerous human activities that often act synergistically and cumulatively with natural disturbances (i.e., droughts or floods) (U.S. Fish and Wildlife Service 2002). These activities include the degradation, fragmentation, and loss of habitat through agriculture, mining, recreation, timber harvesting, nonnative plants, impoundments, water diversions, degraded water quality, introduced predators, and poorly managed infrastructure maintenance activities, such as road construction and repair. These activities can degrade California red-legged frog habitat by increasing disturbance, reducing water quality, or increasing competition and predation pressure.

Habitat along many stream courses has been isolated and fragmented, resulting in reduced connectivity between populations and lowered dispersal opportunities. These isolated populations are now more vulnerable to extinction through stochastic environmental events (i.e., drought, floods) and human-caused impacts (i.e., grazing disturbance, contaminant spills) (Soulé 1998).

In a comprehensive evaluation of prevailing hypotheses on the causes of declines in California red-legged frog populations, Davidson et al. (2001) determined that there is a strong statistical correlation between locations where frog numbers had declined and upwind agricultural land use. They concluded that wind-borne agrochemicals might be an important factor in these declines.

Livestock grazing can have positive or negative impacts on breeding California red-legged frogs depending largely on intensity. Livestock grazing may decrease the suitability of riparian habitat to sustain California red-legged frog populations within the study area. Cattle degrade riparian habitat because they congregate in these areas and trample riparian vegetation. This loss of streamside vegetation can result in increased erosion, increased water temperatures, and reduced numbers of available prey. Conversely, in some grazing areas, artificially created stock ponds provide ideal breeding habitat for California red-legged frog, and grazing may help maintain pond suitability by keeping ponds from being choked with vegetation (U.S. Fish and Wildlife Service 2002).

Finally, gravel mining can degrade habitat by altering the hydrology of aquatic systems, increasing sedimentation, and degrading water quality (U.S. Fish and Wildlife Service 2002).

## Data Characterization

As noted above, the CNDDDB contains 93 documented occurrences of the species in the study area. Existing information should be sufficient to evaluate habitat suitability in the study area. However, much of the HCP/NCCP study area includes private lands that have not been surveyed systematically for this species. The species' ecology, dispersal, and reproduction is relatively well studied.

## Existing Conservation Actions in the Study Area

Biologists from the Santa Clara Valley Water District have surveyed many areas within the streams of Santa Clara County for California red-legged frogs and plan to expand the survey program in upcoming years (U.S. Fish and Wildlife Service 2002; Padley pers. comm.). Other conservation actions for California red-legged frog known in the study area are plans to conduct bullfrog removal in key stock ponds within Henry W. Coe State Park (B. Breckling pers. comm.).

## Modeled Species Distribution in Study Area

### Model Description

#### Model Assumptions

##### Primary Habitat—Breeding and Foraging

All riverine, coastal and valley freshwater marshes, riparian forest/woodland wetlands, ponds (excluding percolation ponds), and natural lakes in riparian forest/scrub, grasslands, oak woodland, chaparral and coastal scrub, conifer woodland, and agriculture land cover types were considered potential breeding and foraging habitat for California red-legged frog.

##### Secondary Habitat—Movement and Refugia

All grassland, chaparral and coastal scrub, oak woodland, riparian forest/scrub, and conifer woodland land cover types within 100 feet of primary habitat are characterized as upland refugia. All grassland, chaparral and coastal scrub, oak woodland, riparian forest/scrub, conifer woodland, and agriculture land cover types beyond 100 feet but within 2 miles of primary habitat are characterized as dispersal habitat.

### Rationale

**Breeding and foraging habitat:** Breeding sites used by California red-legged frogs include a variety of aquatic habitats (Stebbins 1985; Hayes and Jennings 1988). Larvae, tadpoles, and metamorphs use streams, deep pools, backwaters within streams and creeks, ponds, and marshes. Breeding adults are commonly

found in deep (more than 2 feet), still or slow-moving water with dense, shrubby riparian or emergent vegetation (Hayes and Jennings 1988). Adult frogs have also been observed in shallow sections of streams that are not shrouded by riparian vegetation. Generally, streams with high flows and cold temperatures in spring are unsuitable for eggs and tadpoles. Within the Santa Clara Valley HCP/NCCP study area, stock ponds are frequently used as breeding sites by this species. All existing ponds and streams within the study area were, therefore, considered potential suitable breeding habitats for California red-legged frogs.

**Movement and refugia habitat:** During dry weather, California red-legged frogs likely remain in or near water. California red-legged frogs may move over 2 miles up or down drainages from breeding sites and have been observed using adjacent riparian woodlands up to 100 feet from the water (Rathbun et al. 1993). However, as ponds dry out, these frogs disperse from their breeding sites to other areas with water or to temporary shelter or aestivation sites. For this reason, all grassland, chaparral and coastal scrub, oak woodland, riparian forest/scrub, and conifer woodland land cover types within 100 feet of primary habitat are characterized as upland refugia.

Dispersing frogs have been recorded to cover distances from 0.25 mile to more than 2 miles without apparent regard to topography, vegetation type, or riparian corridors (Bulger 1998). This habitat may include small mammal burrows, incised stream channels, shelter under boulders, rocks, logs, leaf litter, agricultural drains, watering troughs, abandoned sheds, or unused farm equipment (Jennings and Hayes 1994). Dispersal and migration movements are generally straight-line, point-to-point migrations rather than following specific habitat corridors (U.S. Fish and Wildlife Service 2000b; Stebbins 2002). They may be along long-established historic migratory pathways that provide specific sensory cues that guide the seasonal movement of the frogs (Stebbins 2002). Dispersal distances are believed to depend on the availability of suitable habitat and prevailing environmental conditions. However, because the actual movement patterns of California red-legged frogs in these habitats is generally not known, for this model we conservatively estimated that all grassland, chaparral and coastal scrub, oak woodland, riparian forest/scrub, conifer woodland, and agriculture land cover types beyond 100 feet but within a radius of two miles from all potential breeding sites were potential migration and/or aestivation habitats for California red-legged frogs.

## Model Results

Figure 2 shows the modeled potential habitat for the California red-legged frog within the study area. Due to the abundance of aquatic habitat in the moderate to high elevations of the study area the associated upland refugia and dispersal habitat is quite expansive. The known occurrences of this species fall within the modeled habitat.

## Foothill Yellow-legged Frog (*Rana boylei*)

### Legal Status

**State:** Species of Special Concern

**Federal:** None

**Critical Habitat:** None

**Recovery Planning:** None

© 2010 William Flaxington

### Taxonomy

Mitochondrial DNA data suggest that *Rana aurora*, *R. cascadae*, and *R. muscosa* form a clade within the *R. boylei* species group (Macey et al. 2001). Descriptions of the species' physical characteristics can be found in Stebbins 2003.

### Distribution

#### General

Historically, foothill yellow-legged frogs occurred from west of the crest of the Cascade mountains in Oregon south to the Transverse ranges in Los Angeles County, and in the Sierra Nevada foothills south to Kern County (Zweifel 1955; Stebbins 2003). The known elevation range of the species extends from near sea level to approximately 2,040 meters (6,700 feet) above sea level (Stebbins 2003). The current range excludes coastal areas south of northern San Luis Obispo County and foothill areas south of Fresno County, where the species is apparently extirpated (Jennings and Hayes 1994) (Figure 1). The foothill yellow-legged frog is still common along the north coast of California (G. Fellers cited by Stebbins and Cohen 1995). Fellers (1994) reported healthy, reproducing populations throughout suitable habitat in the Diablo Range in Alameda, western Stanislaus, Santa Clara, San Benito, and western Fresno counties.

### Occurrences within the Study Area

#### Historical

Historically, foothill yellow-legged frogs were probably present in virtually all of the larger perennial streams in Santa Clara County with the exceptions of the lower portions of Coyote Creek and Guadalupe River (H.T. Harvey and Associates 1999). There are no CNDDDB records for foothill yellow-legged frogs

prior to 1990. The lack of CNDDDB data could be explained by the fact that the California Department of Fish and Game did not require surveyors to submit survey results before 1995 (California Natural Diversity Database 2006).

## Recent

In 1999, H.T. Harvey and Associates summarized the distribution status of the foothill yellow-legged frog for the Santa Clara Valley Water District (H.T. Harvey and Associates 1999). They concluded that, based on their analysis of known locality records, the species had essentially disappeared from the farmed and urbanized lowland areas of the county, as well as many of the perennial streams below major reservoirs. It was determined that though the species is declining throughout Santa Clara County they are still present in the Santa Cruz Mountains and fairly abundant in the foothill and mountain ranges of eastern Santa Clara County (H.T. Harvey and Associates 1999). The extant occurrences as reported by H.T. Harvey and Associates (1999) are captured in the occurrence records for Figure 2.

This species has been found in most perennial streams and rivers in the study area, particularly in the upper reaches. There are several records from the upper reaches of Coyote Creek along with records from nearly all of the streams in the Pajaro River watershed. According to the California Natural Diversity Database (2006), there are nine extant occurrence records of foothill yellow-legged frog in the study area. Seven of the occurrences are on the east side of the valley the northern most of which is in Penetencia Creek. The others are in the Santa Cruz Mountains west of Gilroy.

## Natural History

### Habitat Requirements

Foothill yellow-legged frogs require shallow, flowing water in small to moderate-sized streams with at least some cobble-sized substrate (Hayes and Jennings 1988; Jennings 1988; Bourque 2008). This habitat is believed to favor oviposition (Storer 1925; Fitch 1936; Zweifel 1955) and refuge habitat for larvae and postmetamorphs (Hayes and Jennings 1988; Jennings 1988). This species has been found in streams without cobble (Fitch 1938; Zweifel 1955), but it is not clear whether these habitats are regularly used (Hayes and Jennings 1988; Jennings and Hayes 1994). Foothill yellow-legged frogs are usually absent from habitats where introduced aquatic predators, such as various fishes and bullfrogs, are present (Hayes and Jennings 1986, 1988; Kupferberg 1994). Typical breeding and egg deposition occurs in stream habitat that has little to no slope (U.S. Forest Service 2011). The species deposits its egg masses on the downstream side of cobbles and boulders over which a relatively thin, gentle flow of water exists (Storer 1925; Fitch 1936; Zweifel 1955; Kupferberg 1996). The timing of oviposition typically follows the period of high-flow discharge from winter rainfall and snowmelt (Jennings and Hayes 1994; Kupferberg 1996).

The embryos have a critical thermal maximum temperature of 26°C (Zweifel 1955).

**Table 1.** Habitat Associations for Foothill Yellow-Legged Frog

Land Cover Type	Land Cover Use	Habitat Designation	Habitat Parameters	Rationale
Riparian Woodland	Movement	Primary	Unknown	Nussbaum et al. 1983
Riparian Scrub	Movement	Primary	Unknown	Nussbaum et al. 1983
Aquatic	Breeding	Primary	All life stages occur at aquatic sites	Ibis Environmental Inc. 2003; Morey 2005; U.S. Forest Service 2011

## Reproduction

Foothill yellow-legged frogs in California generally breed between March and early June (Storer 1925; Grinnell et al. 1930; Wright and Wright 1949; Jennings and Hayes 1994). Masses of eggs are deposited on the downstream side of cobbles and boulders. After oviposition, a minimum of approximately fifteen weeks is required to reach metamorphosis, which typically occurs between July and September (Storer 1925; Jennings 1988). Larvae attain adult size in two years (Storer 1925). In a study on the Eel River along the northern coast of California, foothill yellow-legged frog chose sites to lay eggs and timed egg laying to avoid fluctuations in river stage and current velocity associated with changes in river discharge (Kupferberg 1996). This suggests that stable flow and current velocities are important to create suitable reproductive sites for foothill yellow-legged frogs.

Metamorphosis							✓	✓	✓			
Dispersal (metamorphosis)								✓	✓	✓		

Sources: Ibis Environmental, Inc. 2003; Twitty et al 1967.

## Movement

Foothill yellow-legged frogs are a highly aquatic amphibian, spending most or all of their life in or near streams, though frogs have been documented underground and beneath surface objects more than 50 meters (165 feet) from water (Nussbaum et al. 1983). Bourque (2008) reported the movements of radio-tracked frogs being restricted to watercourse, though movement distances were

considerably longer than previously reported with mark recapture techniques. Bourque (2008) found that radio-tagged frogs were relocated on land adjacent to water 37.7% (males) and 65.6% (females). Average distance from water was <3 meters with a range from 6.9–40 meters (Bourque 2008). Distance moved from perennial, ephemeral and intermittent streams was similar. During the breeding season, from March through June, adults and subadults may move several hundred meters or more to congregate at breeding sites (Ibis Environmental, Inc. 2003). Bourque (2008) documented movements up to 578 meters (males) and 7,043 meters (females) during the breeding season. Adult male foothill yellow-legged frogs have high site fidelity during the breeding season and typically occupy small home ranges near breeding site (Bourque 2008).

**Table 3.** Movement Distances for Foothill Yellow-legged Frog

Type	Distance/Area	Location of Study	Citation
Breeding	300 m +	Unknown	Ibis Environmental, Inc. 2003
	578 m (males)	Tehama County, CA	Bourque 2008
	7,043 m (females), median = 525 m	Tehama County, CA	Bourque 2008
Non-breeding	155 feet	Pacific Northwest	Nussbaum et al. 1983

## Ecological Relationships

Garter snakes are considered one of the most prominent predators of foothill yellow-legged frog tadpoles (Fitch 1941; Zweifel 1955; Lind 1990; Jennings and Hayes 1994). Salamanders, including the rough-skinned newt (*Taricha tarosa*), are believed to prey on the species' eggs. The foothill yellow-legged frog coexists with the California red-legged frog (*Rana aurora draytonii*) at some localities, but different microhabitat preferences probably diminish competition (California Wildlife Habitat Relationships System 2005).

## Population Status and Trends

**Global:** Declining (NatureServe 2006)

**State:** Declining (Jennings and Hayes 1994)

**Within Study Area:** Declining (H.T. Harvey and Associates 1999)

## Threats

Habitat loss and degradation, introduction of exotic predators, and toxic chemicals (including pesticides) pose continued and increasing threats to the long-term viability of amphibians throughout California (Jennings and Hayes

1994). In addition, poorly timed water releases from upstream reservoirs can scour egg masses of this species from their oviposition substrates (Jennings and Hayes 1994; Lind 2005; Kupferberg 2009), and decreased flows can force adult frogs to move into permanent pools, where they may be more susceptible to predation (Hayes and Jennings 1988)

Threats include stream scouring (which may negatively impact frogs in streambed hibernation sites), introduced incompatible aquatic animals, riverine and riparian impacts of nonselective logging practices, and stabilization of historically fluctuating stream flows. See Lind et al. (1996), Lind (2005) and Kupferberg et al. (2009) for information on the association of population decline in watershed with dams.

Davidson et al. (2002) found evidence that airborne agrochemicals have played a significant role in the decline of this species; habitat destruction, climate change, and UV-B radiation also appeared to be contributing factors. Lind (2005) further linked changes in land use and use of air-borne toxins on the absence of foothill yellow-legged frogs in areas where they had been previously documented.

Kupferberg (1997) found that bullfrog larvae perturbed aquatic community structure and exerted detrimental effects on *Rana boylei* populations in northern California but had only a slight impact on *Pseudacris regilla*. Interspecific matings between male *R. boylei* and female bullfrogs have been observed; these interactions with nonnative bullfrogs might reduce the reproductive output of *R. boylei* (Lind et al. 2003). Centrarchid fishes readily eat *Rana* eggs (Werschkul and Christensen 1977), and where introduced into foothill streams, may also contribute to the elimination of foothill yellow-legged frogs (Morey 2005).

## Data Characterization

Because the California Department of Fish and Game did not require surveyors to submit survey results before 1995, any recorded occurrences before that time have gone undocumented (California Natural Diversity Database 2006). Few areas within the study area have been surveyed for this species, and several of the observations are incidental. Relatively few areas have been adequately surveyed because of the difficulty of access to private lands within the county (H.T. Harvey and Associates 1999). For this reason a more conservative approach was taken when modeling habitat for this species.

## Existing Conservation Actions in the Study Area

There are no conservation efforts within the study area that directly target the recovery of this species. However, stream restoration projects that return creeks and streams to natural flow regimes will benefit this species.

## Modeled Species Distribution in Study Area

### Model Description

#### Model Assumptions

##### Primary Habitat—Breeding and Foraging

Low gradient streams (0 to 4% slope) or rivers not regulated by a dam, in riparian forest/scrub, grassland, oak woodland, and conifer woodland land cover types.

##### Secondary Habitat—Low Use Habitat

Moderate gradient streams (4% to 10% slope) or rivers in riparian woodland/scrub, grassland, oak savanna, and oak woodland land cover types.

#### Rationale

Foothill yellow-legged frogs are stream-dwelling amphibians that require shallow, flowing water in small to moderate-sized perennial streams, typically with low gradients (U.S. Forest Service 2011), with at least some cobble-sized substrate (Hayes and Jennings 1988; Jennings 1988; H.T. Harvey and Associates 1999). This species has also been found in perennial streams without cobble (Fitch 1938; Zweifel 1955) and has been documented using intermittent and ephemeral stream during fall/winter (Bourque 2008), but it is not clear whether these habitats are regularly used in Santa Clara County (Hayes and Jennings 1988; Jennings and Hayes 1994; H.T. Harvey and Associates 1999). By including all stream types in the model we compensate for under-surveyed areas. Although secondary habitat (moderate gradient streams or rivers) may not support the species and likely have fewer conservation opportunities for this species, those areas were retained in the model output because occurrences have been documented in such habitat.

### Model Results

Figure 2 shows the modeled potential habitat of the foothill yellow-legged frog within the study area. Primary habitat appears to be present in portions of stream habitats with low gradients that are more likely to be perennial. Secondary habitat includes moderate gradient streams. The known occurrences in the study area fall within the modeled habitat, including in many foothill streams near areas of primary habitat.

## Western Pond Turtle (*Clemmys marmorata*)

### Legal Status

**State:** Species of Special Concern; meets requirements as a rare, threatened, or endangered species under the California Environmental Quality Act (CEQA)  
**Federal:** None  
**Critical Habitat:** N/A  
**Recovery Planning:** N/A

### Taxonomy

Western pond turtle is the only species in its genus that occurs in the western United States. This species occurs in 90% of its historic range in the Central Valley and west of the Sierra Nevada Range but in greatly reduced numbers (Jennings and Hayes 1994). There are two recognized subspecies: the northwestern pond turtle (*Clemmys marmorata marmorata*) and the southwestern pond turtle (*Clemmys marmorata pallida*). Genetic research supports the distinctiveness of the two subspecies (Gray 1995; Janzen et al. 1997). The taxonomy is currently under review. A summary of this is outlined by NatureServe (2006). Descriptions of the species' physical characteristics can be found in Stebbins (2003).

### Distribution

#### General

Historically, the western pond turtle had a relatively continuous distribution in most Pacific slope drainages from Klickitat County, Washington, along the Columbia River (Slater 1962) to Arroyo Santo Domingo, northern Baja California, Mexico. In California, it was historically present in most Pacific slope drainages between the Oregon and Mexican borders (Jones & Stokes 2004). The area of the Central Valley of California between the American River drainage and the Transverse Ranges is considered a zone of intergradation between the two subspecies (Seeliger 1945; U.S. Fish and Wildlife Service 1999) (Figure 1).

## Occurrences within the Study Area

### Historical

There are 53 documented occurrences within the study area (California Natural Diversity Database 2006). Of those 53, only 3 were documented before 1985. Though this species is thought to be historically abundant within the study area, there is little information to justify this claim. The fact that the species persists in highly altered aquatic habitat (e.g., channelized waterways and reservoirs) lends support to the idea that it was more abundant when these habitats were in a more natural state.

### Recent

There are 50 known recent occurrences of this species within the study area (California Natural Diversity Database 2006). All of these occurrences were assumed to be extant at the time of documentation. Nearly all were recorded with fair to excellent confidence, leaving only one with poor confidence and seven with unknown confidence. The majority (37) of the occurrences were recorded in the southern half of Santa Clara County. Most are associated with reservoirs or creeks (namely Uvas and Llagas Creeks) as they enter reservoirs. The occurrence data may be bias in favor of areas where observers are likely to make incidental observations (reservoirs, Henry W. Coe State Park, and other park facilities). Western pond turtles have been documented throughout the Coyote Creek drainage from the upper reaches in Henry W. Coe State Park to the urbanized reaches in San José (California Natural Diversity Database 2006).

## Natural History

### Habitat Requirements

Western pond turtles occur in a variety of aquatic habitats from sea level to elevations of 6,500 feet. They are found in rivers, streams, lakes, ponds, wetlands, reservoirs, and brackish estuarine waters (Holland 1994; Jennings and Hayes 1994). Western pond turtles use aquatic habitats primarily for foraging, thermoregulation, and avoidance of predators. They prefer habitats with large areas for cover (such as logs, algae, and vegetation) and basking sites (such as boulders or other substrates). The species has been observed to avoid areas of open water lacking these habitat features (Holland 1994). Both adult and juvenile turtles favor aquatic habitats with access to areas of deep, slow water with underwater refugia. Hatchlings are relatively poor swimmers and tend to seek areas with shallow, warm water, free of predatory aquatic vertebrates, with at least some aquatic vegetation (Reese 1996; Holland 1994; Jones & Stokes 2004).

Western pond turtles overwinter in both aquatic and terrestrial habitats. Aquatic refugia consist of rocks, logs, mud, submerged vegetation, and undercut areas

along banks. Terrestrial overwintering habitat consists of burrows in leaf litter or soil. The presence of a duff layer seems to be a general characteristic of overwintering habitat (Jones & Stokes 2004; Holland 1994; Davis 1998).

**Table 1.** Land Cover Type Associations for Western Pond Turtle

Land Cover Type	Land Cover Use	Habitat Designation	Habitat Parameters	Rationale
Wetlands	Foraging, thermoregulation, refuge	Primary	Cover and basking sites	Holland 1994
Aquatic	Foraging, thermoregulation, refuge	Primary	Cover and basking sites	Holland 1994
Shrub dominated	Nesting	Primary	Sunny and relatively undisturbed	Rathbun et al. 2002; Jennings and Hayes 1994
Herbaceous dominated	Nesting	Primary	Sunny and relatively undisturbed; some grazing is tolerated	Rathbun et al. 2002; Jennings and Hayes 1994
Riparian woodland	Refugia, thermoregulation	Secondary	Well developed riparian corridor protects aquatic habitats	Holland 1994; Jennings and Hayes 1994
Riparian scrub	Refugia, thermoregulation	Secondary	Well developed riparian corridor protects aquatic habitats	Holland 1994; Jennings and Hayes 1994

## Reproduction

Western pond turtles first breed at 10 to 14 years of age (U.S. Fish and Wildlife Service 1999; Stebbins 2003). Most females lay eggs in alternate years. Clutch size ranges from 1 to 13 eggs, with larger females generally laying larger clutches (Holland 1985a, 1991a). Gravid females leave drying creeks from May through July to deposit their eggs in sunny, upland habitats, including grazed pastures and agricultural fields (Crump 2001). Nesting has been reported to occur up to 402 meters (1,391 feet) from water (Jennings and Hayes 1994) but is usually closer, averaging 28 meters (92 feet) from aquatic habitat (Rathbun et al. 2002). Incubation lasts 80 to 100 days, and the normal hatch success is approximately 70%. Nest predation rates are high, and complete failure of nests is common.

**Table 2.** Key Seasonal Periods for Western Pond Turtle

## Movement

Western pond turtles utilize a home range on the order of several hundred meters (Holland 1994), with males using a larger aquatic home range than females. Individuals may occasionally make sporadic long-distance aquatic movements outside their home range (Holland 1994). Gravid females usually leave the water to nest on land in the late afternoon or evening, returning to the water by morning, although this is quite variable (Crump 2001). Nest sites have been found as far as 400 meters from the water (Reese 1996). Reese (1996) found that over the summer months (May–September), juvenile turtles have an average maximum movement of approximately 84 meters. Their mean weekly aquatic travel is 19.9 meters. Their home range is smaller than that of adults but larger than previously recognized and also includes terrestrial components (Reese 1996). Juveniles sometimes travel back and forth between low-flow portions of the river and adjacent ponds.

**Table 3.** Movement Distances for Western Pond Turtle

Type	Distance/Area	Location of Study	Citation
Home range (aquatic)	>100m from watercourse to upland	Oregon	Holland 1994
Movement to nesting sites from watercourse	Up to 400m	Northern California	Reese 1996
Movement to overwintering sites from home range	~167m	Northern California	Reese 1996

## Ecological Relationships

Western pond turtles are considered dietary generalists, but they do not select food items based on general availability (Bury 1986). This species prefers live prey, which it captures by opportunistic foraging tactics. Individuals will also scavenge carrion and browse on plant material. Prey items are ingested in the water; it appears this species is unable to swallow in air (Holland 1994). Preferred food items include aquatic insect larvae, crustaceans (cladocerans and crayfish), and annelids. Small vertebrates (including *Rana boylii* tadpoles and

egg masses) have been found during gut content analysis of *C. marmorata*, but it is unclear whether these were ingested as prey or carrion (Bury 1986; Holland 1994).

Several common predator prey on western pond turtles. These predators include, but are not limited to raccoon (*Procyon lotor*), coyote (*Canis latrans*), grey fox (*Urocyon cinereoargenteus*), and feral and domestic dogs (*Canis familiaris*) (Holland 1994). Adult turtles often show scarring on the shell and/or missing limbs, indicating attempted predation.

Hatchlings are especially vulnerable to predators because their shell is soft and they can be swallowed whole. Overland movements from the nest site to the aquatic habitat expose turtles to a wide range of terrestrial predators. Holland (1994) found a six-fold greater scarring rate on females and attributed it to greater exposure to predators during nesting movements. Exotic aquatic predators, such as bullfrogs (*Rana catesbeiana*) and largemouth bass (*Micropterus salmoides*), can be especially effective at reducing recruitment in this species when turtles arrive at the preferred aquatic microhabitat after leaving the nest site (Holland 1994).

## Population Status and Trends

**Global:** Declining (Bury 1986; NatureServe 2006)

**State:** Unknown

**Within Study Area:** Unknown

The species is declining throughout its range, more so in Washington and Oregon than in California (NatureServe 2006). The status of the population in California is not well understood but decline is generally attributed to a loss of nesting habitat (see below).

## Threats

Numerous factors, including loss, degradation, and fragmentation of habitat; disease; introduced predators and competitors; and other natural and anthropogenic conditions present ongoing threats to western pond turtles throughout 75–80% of its range (U.S. Fish and Wildlife Service 1999; Holland 1991a).

Recent studies describe populations that have adults but few juveniles, indicating that little or no reproduction is taking place (Jones & Stokes 2004). Because pond turtles are long-lived, non-reproducing populations may persist in isolated wetlands long after recruitment of young has ceased (Holland 1991a; Jennings and Hayes 1994; U.S. Fish and Wildlife Service 1999).

## Data Characterization

Currently, the sizes and densities of western pond turtle populations in California are not well known. Information on dispersal, population structure, population dynamics, and the nature and dynamics of environmental factors affecting populations (including edge effects) is needed to effectively design and implement conservation plans. In addition, the current genetic diversity of existing populations should be investigated to determine metapopulation status, gene flow between populations, and long-term population viability.

## Existing Conservation Actions in the Study Area

There are currently no known conservation actions in the study area that target this species. However, any creek or stream restoration that returns altered aquatic systems to a natural setting will benefit the western pond turtle.

## Modeled Habitat Distribution in Study Area

### Model Description

#### Model Assumptions

##### **Primary Habitat—Nest Sites, Basking, Overwintering**

All ponds, streams, canals/ditches, and coastal and valley freshwater marsh are considered primary habitat. In addition, areas within 150 feet of these landcover types are considered suitable nesting and overwintering habitat. There would be an exception to this rule if the landcover within this 150 feet buffer consisted of rock outcrops, vineyards, orchards or urban areas.

##### **Secondary Habitat—Nest Sites and Movement**

Movement habitat includes all land cover types within 1,200 feet of primary habitat with the exception of areas within this buffer that consist of rock outcrops, vineyards, orchards or urban areas.

### Rationale

The western pond turtle is a thoroughly aquatic turtle of ponds, marshes, rivers, streams, and irrigation ditches with aquatic vegetation (Jennings and Hayes 1994). Gravid females oviposit in sunny upland habitats, on grassy banks and in grazed pastures. Nesting has been reported to occur up to 402 meters (1,391 feet) from water (Jennings and Hayes 1994), but is usually closer, averaging 28 meters (92 feet) from aquatic habitat (Rathbun et al. 2002). To accommodate this range but remain conservative, a buffer distance of 150 feet from all aquatic habitat was used to model primary habitat for this species. Nests have been observed in

many soil types, from sandy to very hard. Soil must usually be at least 10 cm (4 in) deep for nesting, and nests must have a relatively high internal humidity for eggs to develop and hatch properly (Zeiner 1988). To account for long-distance dispersal to nest sites or movement between water bodies, the distance of 1,200 feet from all aquatic habitat was used to model habitat suitable for this purpose. Though this is not all inclusive of the documented 1,391 foot dispersal by Jennings and Hayes (1994), it likely still overestimate the actual upland habitat use by this species.

## Model Results

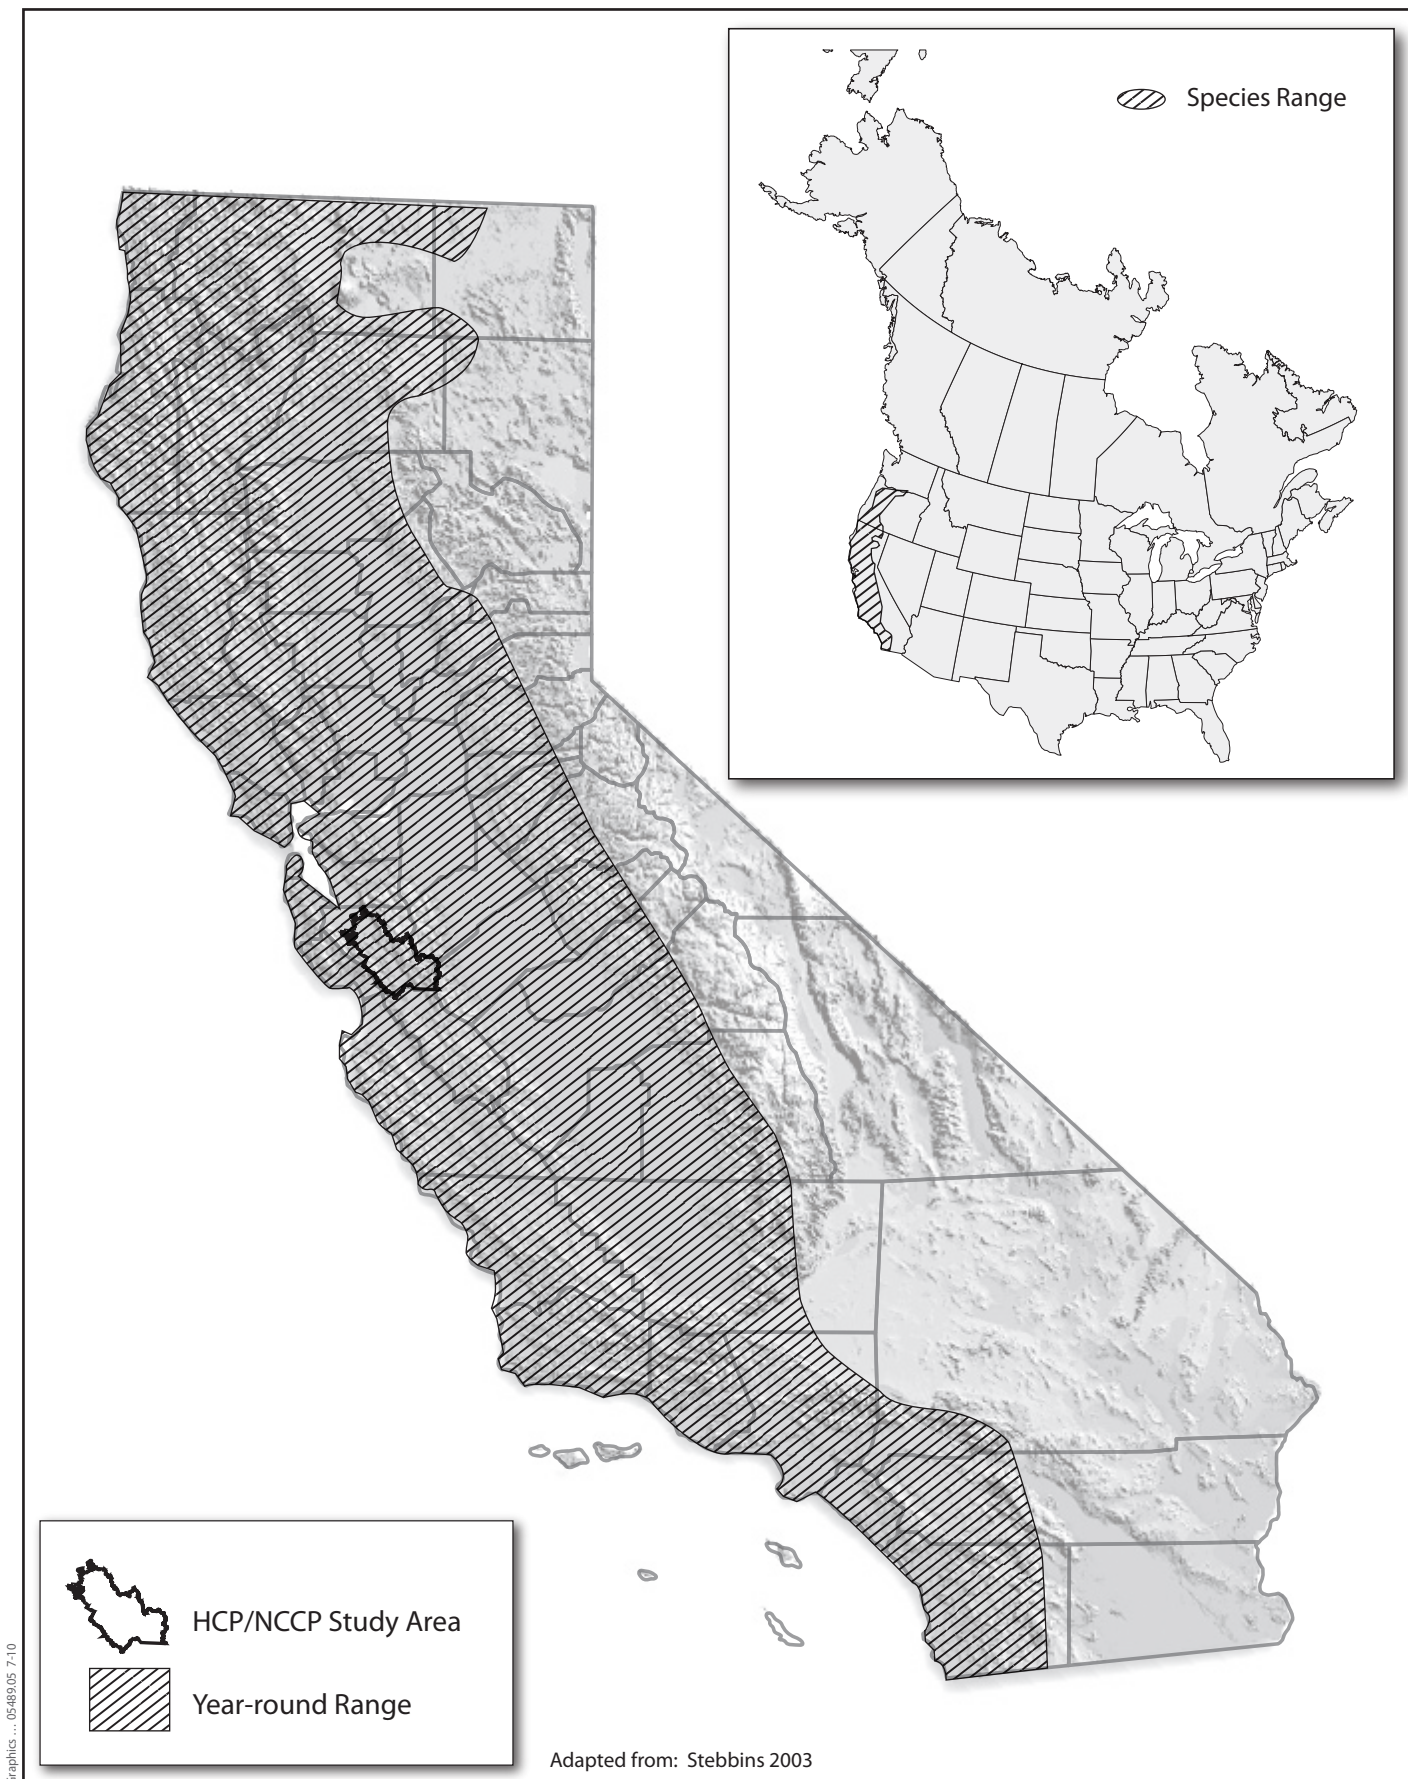

Figure 2 shows the modeled potential habitat of the western pond turtle within the study area. Primary habitat is prevalent in the study area due to the abundance of streams and ponds, particularly in the areas above the valley floor. Movement habitat is found throughout the western and eastern portions of the study area adjacent to streams and ponds. The documented occurrences of western pond turtle in this study area correspond well to locations within the identified suitable habitat and movement corridors.

## Western Burrowing Owl (*Athene cunicularia hypugaea*)

### Legal Status

**State:** Bird Species of Special Concern, *Second Priority* (Shuford and Gardali 2008)

**Federal:** Migratory Bird Treaty Act (16 USC 703–712); National Bird of Conservation Concern (U.S. Fish and Wildlife Service 2002)

**Critical Habitat:** N/A

**Recovery Planning:** N/A

**Notes:** The burrowing owl has been included on the list of California Species of Special Concern since 1978 (Remsen 1978; Shuford and Gardali 2008). In 2003 a petition to list the burrowing owl as threatened or endangered under the California Endangered Species Act (Center for Biological Diversity et al. 2003) was rejected by the California Fish and Game Commission (Miller 2007). Another petition could be submitted and the owl's status could change.

© 2005 Tom Greer

### Taxonomy

Up to 21 subspecies of burrowing owls have been recognized (Clark 1997), but only one subspecies (*Athene cunicularia hypugaea*) occurs in North America west of the Great Plains (Haug et al. 1993). Descriptions of the species' physical characteristics, behavior, and distribution are provided in a variety of field guides (e.g., Peterson 1990; Sibley 2000; National Geographic 2002).

### Distribution and Abundance

#### Distribution

The western burrowing owl is found throughout non-mountainous western North America, from the Great Plains grasslands in southern portions of the western Canadian provinces south through the U.S. into Mexico (Haug et al. 1993). Other burrowing owl subspecies occur in arid, open habitats in Florida, the Caribbean Basin, and South America (Haug et al. 1993; Clark 1997) (Figure 1).

In California, the burrowing owl's range extends throughout the lowlands from the northern Central Valley to Mexico, with a small (perhaps extirpated) population in the Great Basin bioregion in northeast California (Cull and Hall 2007) and the desert regions of southeast California (Gervais et al. 2008). Breeding burrowing owls are absent from the coast north of Sonoma County and

from high mountain areas, such as the Sierra Nevada and the Transverse Ranges extending east from Santa Barbara County to San Bernardino County (Gervais et al. 2008).

A statewide survey of burrowing owl abundance and distribution, exclusive of northeastern California and the eastern deserts, conducted by The Institute for Bird Populations from 1991–1993 (DeSante et al. 2007), showed that the distribution and abundance of burrowing owls in California was not uniform and owl numbers and densities varied considerably among and within the regions surveyed (see below).

Although the overall range of the burrowing owl in California has not drastically changed since summarized by Grinnell and Miller (1944), the species has disappeared as a breeding bird from portions of its former range (Center for Biological Diversity et al. 2003; DeSante et al. 2007; Miller 2007; Gervais et al. 2008). The statewide survey indicated that breeding burrowing owls had disappeared from the central coast (Marin, San Francisco, Santa Cruz, Napa, and coastal San Luis Obispo counties), Ventura County, and the Coachella Valley. At the time of the statewide survey, breeding owls had nearly been extirpated from Sonoma, Santa Barbara, Orange, coastal Monterey and San Mateo counties, where only one to two known breeding pairs remained (DeSante et al. 2007). The listing petition (Center for Biological Diversity et al. 2003; Miller 2007) suggested that breeding burrowing owls have functionally disappeared from 22% of their former range and continue to decline in an additional 23% of their range.

## Abundance

Burrowing owls were first mentioned to be declining in several regions in California as early as the 1940s by Grinnell and Miller (1944) who noted that burrowing owls were becoming scarce in more settled parts of the state due, in some part, to ground squirrel shooting and eradication. All of the available information suggests that burrowing owl populations in several parts of the state declined during the second half of the 20<sup>th</sup> century. The annual Christmas Bird Count records from 1954 to 1986 showed significant owl declines in California, beginning in the 1970s (James and Ethier 1989). Most ornithologists agree that the species has been declining over the past forty years in many parts of the state (Gervais et al. 2008).

DeSante et al. (2007) estimated the state's burrowing owl population at 9,266 pairs with 71% (6571 pairs) of California's burrowing owls (exclusive of northeastern California and the eastern deserts) occurring in the Imperial Valley (which is less than 3% of California) and 24% in the Central Valley. The remaining 5% were in the western part of the state in the San Francisco Bay area, the central coast, and southern California. They also concluded that 92% of the breeding owls in California occurred in lowland areas generally below 200 feet (60 meters) elevation.

The burrowing owl population in the San Francisco Bay area, estimated at 165 breeding pairs in the early 1990s (DeSante et al. 1997; DeSante et al. 2007) was

thought to have declined 50% between the 1980s and early 1990s. Breeding owls were greatly reduced in numbers or extirpated from many portions of the San Francisco Bay area (DeSante et al. 1997; DeSante et al. 2007; Townsend and Lenihan 2007). Likewise, breeding owls have declined or disappeared throughout southwestern California (Kidd et al. 2007; Lincer and Bloom 2007; Miller 2007).

## Occurrences within the Study Area

### Historical

At the beginning of the 20<sup>th</sup> century, the burrowing owl was recognized as a common bird of Santa Clara County (Price 1898; Fisher 1904; Van Denburgh 1899). Several years later, Grinnell and Wythe (1927) still found that owls were a “fairly common resident in the drier, unsettled interior parts of the region,” being most abundant in Alameda, Contra Costa and Santa Clara counties. In 1951, Sibley still saw adults and young at a location in what is now downtown San José (Sibley 1952).

Early references to the status of burrowing owls in the San Francisco Bay area (Grinnell and Wythe 1927; Grinnell and Miller 1944) consisted of qualitative comments on owl distribution and numbers rather than numerical population estimates because there had been no systematic population surveys. The pattern of land use practices and their effects on owl habitat since the 1960s provides a source of information about general trends in owl numbers. In the 1960s land use (evident in historical aerial photographs) in the Santa Clara Valley was primarily agricultural with orchards and row crops most common. The process of converting orchards to other uses, including commercial development, and abandoning agricultural uses, beginning in the late 1960s and early 1970s, probably increased burrowing owl nesting opportunities. Orchards cleared for development temporarily transformed unsuitable habitat into owl foraging habitat. Such areas became nesting habitat for owls as soon as they were colonized by ground squirrels (which were ubiquitous) as long as the vegetation was maintained short. Nesting owls often occupied such lands the first spring after orchard removal. With hundreds of burrowing owls nesting in the region, lands cleared of orchards were well within dispersal distance for young from nearby territories.

In the 1970s, burrowing owls occurred along the west side of the San Francisco Bay where there were perhaps two dozen pairs in all of south San Francisco, San Mateo, and Redwood City baylands. Owls became much more common moving south around the south end of the bay where there were dozens of pairs in several colonies immediately upland of the baylands in Palo Alto, Mountain View, Sunnyvale, Santa Clara, Alviso, San José, Milpitas, and Newark. Moving up the east side of the bay owls again became less common with perhaps less than two dozen pairs in the Hayward and San Leandro baylands, and small colonies at the Oakland Airport (Thomsen 1971) and Alameda Naval Air Station.

Owls occupied cemeteries, golf courses, road medians, margins of landfills, and other types of grassland-dominated open space in this region. Owls also occupied airports (Thomsen 1971; Trulio 1994; Barclay 2007), railroad yards, and fallow agricultural fields. Development has greatly reduced, and in most areas entirely eliminated, burrowing owl habitat since the 1970s. Trulio (1998) sampled sites known to be occupied by burrowing owls in the Silicon Valley and reported that during the years where data was collected (1981–1988, 1995, and 1998), 70 (57%) of the 123 sites were developed. South of San José in the Santa Clara Valley, burrowing owl abundance declined and the species occurred in more widely scattered colonies or individual pairs, as in Morgan Hill, until the early 2000s (California Natural Diversity Database 2009).

We have no precise estimates of the burrowing owl population in the San Francisco Bay area in the second half of the 20<sup>th</sup> century because there had been no systematic population surveys until 1991–1993 (DeSante et al. 1997; DeSante et al. 2007). The burrowing owl population in the entire south San Francisco Bay area was probably in the neighborhood of 1000 pairs in the 1970s and by 1980 perhaps only 250 pairs remained (Albion Environmental, Inc. 2000a).

DeSante et al. (1997) estimated there were 873 pairs of owls in central California (i.e., Outer Coast, San Francisco Bay area, Central Valley) in the early 1990s. Estimates of the numbers in the San Francisco Bay area were 153 pairs (DeSante et al. 1997) and 165 (DeSante et al. 2007). Results of the statewide survey suggested that there had been approximately 50% declines in both the numbers of owls and the number of breeding groups in the San Francisco Bay area from the period 1986–1991 (DeSante et al. 1997; DeSante et al. 2007). Generally, burrowing owls were most abundant in colonies in grasslands growing on the alluvial plain surrounding the south end of San Francisco Bay immediately upland of south bay marshes (i.e., baylands), and few owls occurred above 200 feet elevation in this region (DeSante et al. 1997; DeSante et al. 2007).

## Recent

### Santa Clara County

As of July 2009, there were 53 occurrences of burrowing owls in Santa Clara County in the California Natural Diversity Database (California Natural Diversity Database 2009). Many of these occurrence records include sightings of several breeding individuals over multiple years. Forty-nine (95%) of the extant occurrences have been reported in the study area since 1990. Burrowing owls were commonly encountered during environmental assessments for development projects throughout the Santa Clara Valley. However, in many cases survey results were not reported to the California Natural Diversity Database, so this source of information is incomplete and cannot be used to derive population estimates or trends.

Using information from various unpublished sources, the burrowing owl population in Santa Clara County in 1997 was estimated to range from 120 to 141 pairs (Table 1; Albion Environmental, Inc. 2000a). Most of these owls occurred at 12 locations where there was more than one pair. At least 10 of these

locations could be termed colonies averaging five or more pairs. Approximately one-third of the county population (43–47 pairs) occurred within the City of San José (Table 1; Albion Environmental, Inc. 2000a). The Santa Clara Valley Water District performed surveys at 41 sites throughout Santa Clara County in the summer of 1998, but detected no burrowing owls at any of these sites, nor in potential habitats adjacent to the project sites (Santa Clara Valley Water District 1998). A survey of 53 sites in the City of San José in 2000 estimated 39 to 40 pairs of owls (Table 1; Albion Environmental, Inc. 2000b).

The HCP/NCCP area was surveyed for breeding burrowing owls from 26 May to 23 July 2008 (Albion Environmental, Inc. 2008a). This survey was conducted at 96 locations: 84 locations inside the HCP/NCCP area and 12 immediately outside the northern and southern boundaries of the HCP/NCCP area where breeding owls were known to occur, i.e., Alviso environs and northern San Benito County. This survey resulted in an estimate of 19–20 pairs in the HCP/NCCP area, 20 to 21 pairs in the City of San José (includes pairs in Alviso outside the plan area) and 21 to 23 breeding pairs when including pairs observed just outside the north and south HCP/NCCP plan area boundaries (Table 1). However, all except two breeding pairs in the plan area were located on either San José International Airport or north San José/Alviso (Albion Environmental, Inc. 2008a).

Owls were observed at 10 (10%) of the 96 locations surveyed. Survey results were sufficient to conclude that owls were absent at 61 (64%) of the locations surveyed and burrowing owl presence/absence was inconclusive (because of limited access or visibility) at 25 (26%) of the locations surveyed. Twenty-two (23%) of the locations surveyed were completely developed and contained no habitat for burrowing owls (Albion Environmental, Inc. 2008a).

**Table 1.** Pairs of burrowing owls known in the City of San José in 1997, 2000 and 2008

Location	Number of pairs		
	1997*	2000**	2008
San José International Airport	15	21	8
Alviso including Water Pollution Control Plant buffer lands	17	14–15	7 (3 single adults)

Undisclosed location	3	1	1
Single pairs at other locations	5	2	0
Total pairs	43–47	39–40	20–21 pairs (3 single adults)

In 2009, 10 locations where burrowing owls had been observed in 2008 or in recent years were surveyed again (Albion Environmental, Inc. unpublished data). Fifteen pairs comprised of 34 adults were recorded in the HCP/NCCP area and 18 pairs, including three pairs observed outside the plan boundary, in northern San Benito County. This suggests a further decline from the 19 to 20 pairs recorded in the plan area in 2008 (Albion Environmental, Inc. 2008a). However, the survey effort in 2009 was much less thorough than in 2008 and some breeding pairs may have been missed.

The City of San José is the only area for which estimates of the numbers of pairs of owls in 1997, 2000, and 2008 can be used to suggest a regional trend across this time period. Based on an estimate of 43–47 pairs in 1997, 39–40 pairs in 2000 and 20–21 pairs in 2008 the population in the City of San José has declined approximately 50% since 1997 (Table 1; Albion Environmental, Inc. 2000a, 2000b, 2008a).

## Natural History

The burrowing owl's life history and reproductive strategy show that it is relatively short-lived, reaches sexual maturity at one year old, has high fecundity and breeding adaptations to take advantage of annual fluctuations in food supply (Newton 1977), and has low juvenile (i.e., first year) and moderate adult survival rates. These characteristics suggest that burrowing owl populations should be expected to change in response to environmental conditions over short time periods.

## Habitat Requirements

Throughout their range, burrowing owls require habitats with three basic attributes: open, well-drained terrain; short, sparse vegetation generally lacking trees; and underground burrows or burrow facsimiles (Klute et al. 2003; Gervais et al. 2008). During the breeding season, they may also need enough permanent cover and taller vegetation within their foraging range to provide them with sufficient prey, which includes large insects and small mammals (Haug et al. 1993; Wellicome 1997). Burrowing owls occupy grasslands, deserts, sagebrush scrub, agricultural areas (including pastures and untilled margins of cropland), earthen levees and berms, coastal uplands (especially by over-wintering migrants, California Natural Diversity Database 2009), and urban vacant lots, as well as the margins of airports, golf courses, and roads (Gervais et al. 2008).

## Vegetation

Vegetative cover and height are significant factors due to the semi-fossorial nature and small size of the burrowing owl (Zarn 1974; Coulombe 1971; Green and Anthony 1989; Trulio 1994). These owls prefer open habitats that afford visibility of approaching predators (Zarn 1974) or contain elevated perches for the same purpose (Green 1983). However, they will tolerate tall vegetation (especially in the rainy season in the early part of the nesting cycle in California) if it is sparse or patchy with open spaces. Low-growing vegetation may provide hiding sites for young owls (MacCracken et al. 1985) and increase hunting efficiency (Johnsgard 1988). Green (1983) found that owls in Oregon avoided habitat with vegetation that impaired the owls' horizontal visibility and did not provide elevated perches. Owls will perch on raised burrow mounds or other topographic relief such as rocks, tall plants, fence posts, and debris piles to attain better visibility (Haug et al. 1993). Tall or dense vegetative cover that prevents

visibility of approaching predators puts burrowing owls at a severe disadvantage. Green and Anthony (1989) found that owls selected areas for nesting with a greater percentage of bare ground than areas where owls did not nest. In the Columbia Basin, an average of 28% cover in occupied owl habitat was reported (Green and Anthony 1989). In Oklahoma, Butts (1973) reported that owls occupied areas where vegetation was 4 inches or less.

At Moffett Federal Airfield in Santa Clara County, occupied burrowing owl habitat contained 44–57% cover, while the average cover in unoccupied fields was 85% (Trulio 1994). Vegetation height averaged 5.6 inches directly around burrows in occupied habitat versus 10.4 inches in unoccupied fields (Trulio 1994). Owls are often found in human-altered habitats such as grazed areas, areas sprayed with herbicide, and areas where vegetation has been removed without harming burrows. These conditions allow owls to stand near the burrow entrance and effectively watch for approaching predators (Coulombe 1971; Green and Anthony 1989; Trulio 1994). Coulombe (1971) noted that burrowing owls abandoned their burrows when vegetation grew too thick or high.

## Burrows

The presence of burrows, usually excavated by fossorial mammals such as ground squirrels or prairie dogs, is a critical component of suitable habitat for burrowing owls because burrows provide security for nesting and shelter from predators and weather. Studies have found that burrow tunnel cross-sections averaged 4.7 by 7.5 inches (12 by 19 centimeters [cm]) (Martin 1973), and enlarged chambers used for nesting averaged 9.8 inches wide by 4.4 inches high (25 cm wide by 11 cm high) (Butts 1973). Tunnels usually slant 15 degrees downward (Zarn 1974).

Owls use burrows dug by other animals such as ground squirrels (*Spermophilus* spp.), badgers (*Taxidea taxus*), and prairie dogs (*Cynomys* spp.), kangaroo rats (*Dipodomys* spp.) and tortoises (*Gopherus* spp.) (Zarn 1974). Burrowing owls in the western U.S. usually dig only to renovate and maintain their burrows, but they are capable of excavating entire burrows (Thomsen 1971; Barclay 2007). Owls often use unlined earthen banks along agricultural irrigation canals and ditches (Haug et al. 1993) especially in the Imperial Valley (Colombe 1971; DeSante et al. 2004; Rosenberg and Haley 2004). Sandy, well-drained soils may be favored for burrows because of the ease of enlargement and rapid drainage after rainfall (Johnsgard 1988). A family group may use up to 10 different burrow entrances in one year (Winchell 1994; Johnson 1986).

At Moffett Federal Airfield, Trulio (1994) reported an average burrow density of 63 burrows/acre in fields where owls nested. Burrow density was much higher around active owl nests, where the average burrow density was approximately 200 burrows/acre in a 24-foot radius around active nests (Trulio 1994). In fields not occupied by owls for 5 years, the average burrow density was 7 burrows/acre. Coulombe (1971) reported that the number of available burrow sites was apparently the major factor controlling the abundance of burrowing owls in the Imperial Valley of California. Grant (1965) indicated that nesting areas are

always in the vicinity of perch sites such as fences, utility poles, or the raised mounds around rodent burrows. Winchell (1994) observed 136 burrowing owls utilizing 224 separate burrows, 56 of which contained nests, showing that burrowing owls use more than one burrow within their home range. Other studies have noted that it is common for juveniles to use satellite burrows farther away from the nest site as they begin to fly and disperse (Zarn 1974). Rich (1984) found that 39% of burrows used by burrowing owls were reused the following year.

In natural settings, burrowing owls often occupy burrows under protective surfaces such as rock (Rich 1984), lava flows (Gleason and Johnson 1985), and limestone (Coulombe 1971), perhaps as a protection against digging predators (Rich 1984) or collapse by natural processes. In human-modified environments owls often use burrows under the edges of concrete, asphalt, and rubble piles.

Burrowing owls also use artificial burrows installed to increase burrow availability (Collins and Landry 1977; Poulin 2000; Smith and Conway 2005; Barclay 2008), mitigate effects of development projects (Trulio 1995; Smith and Belthoff 2001), conserve individual colonies (Hjertaas 1997; Barclay 2007), facilitate reintroductions (Leupin and Low 2001; Martell et al. 2001; Poulin et al. 2006), enhance conservation (Wellicome et al. 1997; Smith and Conway 2005; Smith et al. 2005), and enable research on aspects of breeding biology not easily studied in natural burrows (Henny and Blus 1981; Haug et al. 1993; Wellicome 1997, 2005; Poulin and Todd 2006; Barclay 2008). Barclay (2007) reported a 43% occupancy rate of artificial burrows by adult owls during the nesting season at San José International Airport over an 11-year period.

**Table 2.** Habitat Associations for Western Burrowing Owl

Land Cover Type	Land Cover Use	Habitat Designation	Habitat Parameters	Rationale
Herbaceous dominated	Nesting, shelter, refugia	Primary	Burrows mostly dug by other animals including the California ground squirrel	The presence of nest burrows, dug by fossorial mammals such as ground squirrels, seem to be a critical requirement for burrowing owls. Typically forage in habitats characterized by low-growing vegetation (Haug et al. 1993). Often use unlined earthen banks along agricultural ditches vegetation (Haug et al. 1993)
Agricultural	Nesting, shelter, refugia	Secondary	See above	See above
Ruderal	Nesting, shelter, refugia	Secondary	See above	See above; may use urban levees if suitable burrows are available (Haug et al. 1993)
Urban-Suburban	Nesting, shelter, refugia	Secondary	See above	See above; may use urban levees if suitable burrows are available (Haug et al. 1993)
Rural residential	Nesting, shelter, refugia	Secondary	See above	See above; may use urban levees if suitable burrows are available (Haug et al. 1993)

## Diet

Burrowing owls are opportunistic predators that will consume arthropods, small mammals, birds, amphibians, and reptiles (Haug et al. 1993; Karalus and Eckert 1987; Gervais et al. 2008). Owls typically forage in habitats characterized by low-growing, sparse vegetation (Haug et al. 1993). Insects are often taken during the day, especially during the summer, while small mammals are taken at night. In California, crickets and meadow voles (*Microtus* sp.) were found to be the most common food items (Thomsen 1971). Nocturnal foraging can occur up to several kilometers away from the burrow; and owls concentrate their hunting on uncultivated fields, ungrazed areas, and other habitats with an abundance of small mammals (Haug and Oliphant 1990). In urban areas, burrowing owls are often attracted to streetlights, where insect prey congregates.

## Reproduction

Burrowing owls reach sexual maturity at one year of age. Nesting in California generally runs from February through August, with peak activity from mid-April to mid-July (Zeiner et al. 1990; Thomsen 1971; Gervais et al. 2008). Burrowing owls are primarily monogamous and typically breed once per year; however, Gervais and Rosenberg (1999) reported burrowing owls producing a second brood of young in the Central Valley. Clutch sizes range from one to eleven eggs (Murray 1976) and average eight eggs (Haug et al. 1993). The number of eggs laid is affected by prey abundance: the more food that is provided to the female the more eggs tend to be laid (Wellicome 1997). Incubation lasts 28–30 days. Females supplemented with food can have higher reproductive success than females without supplemented food, which may explain poor reproductive success in areas with low-quality foraging habitat (Wellicome 1997). An average of 78% of potentially reproductive pairs at Moffett Airfield (Trulio 1994, 1997) produced emergent young over seven breeding seasons. Trulio and Chromczak (2007) reported an average of 51% of urban nests produced young compared to 45% of parkland nesting successful over a seven year period in northern Santa Clara County.

The female performs all the incubation and brooding and stays in the burrow nearly continuously while the male does the provisioning. Because incubation begins before the clutch is complete, eggs hatch asynchronously. Asynchronous hatching is an adaptation to annual variation in prey abundance, whereby more young can be raised during years when prey is plentiful (Newton 1977, 1979; Wellicome 2005). The young begin emerging from the nest burrow when about two weeks old, and they remain closely associated with the nest burrow or nearby satellite burrows for several weeks (Thomsen 1971). As the young mature they begin venturing farther from the natal burrow, sometimes abandoning it entirely and moving to a satellite burrow(s). Young burrowing owls fledge at 44 days but usually remain in the natal territory, and as they mature they join the adults in foraging flights at dusk (Rosenberg et al. 1998).

## Territory and Home Range

Thomsen (1971) calculated an average territory size (defended area around the nest burrow) of 1.98 acres (range 0.1–4.0 acres) for six territories studied at the Oakland, CA, Airport. Rosenberg and Haley (2004) reported average nearest neighbor distances from 125–166 meters (410–546 feet.) in the Imperial Valley. Martin (1973) reported an average distance of 545 feet between occupied burrows in New Mexico, yielding an estimated territory of 5.4 acres.

Home range, which is the entire area of an animal's movements for foraging, roosting, nesting and raising young, likely varies depending on local habitats present and local prey resources (Gervais et al. 2008). Rosenberg and Haley (2004) reported estimates of 114 hectares (280 acres) for the area traversed and 45 hectares (111 acres) for the area used by burrowing owls in the Imperial Valley. Rosenberg and Haley (2004) found that >80% of nocturnal foraging of telemetered owls in the Imperial Valley was within 600 meters of the nest, but long-distance movements also occurred. Home ranges for six radio-marked owls in Saskatchewan ranged from 35 to 1,200 acres with an average of 595 acres (Haug and Oliphant 1990). Activity data in this study showed that owls spent most of the daylight hours within 164 feet of the nest burrow and never traveled farther than 820 feet of the nest burrow during the day. Nocturnal activity data showed owls flew long distances to forage at night (maximum of 8859 feet, 1.6 miles) from their nest, but 95% of movements were within 1968 feet (0.4 miles) from their nest (Haug and Oliphant 1990).

## Movement, Migration, and Dispersal

California supports year-round resident burrowing owls and over-wintering migrants (Gervais et al. 2008). Dispersal in burrowing owls that nest in California is variable depending on location and the age of the owls. Many owls remain resident throughout the year in their breeding locales (especially in central and southern California) while some apparently migrate or disperse in the fall (Haug et al. 1993; Coulombe 1971; Barclay et al. 2007). Owls breeding in northern California locales and at higher altitudes (e.g., Modoc Plateau) are believed to move south during the winter (Grinnell and Miller 1944; Zeiner et al. 1990). Thomsen (1971) reported that owls stayed on their breeding grounds in

Oakland during the winter and remained in their burrows in the daytime. Other researchers report that burrowing owls may “wander” during the winter months, occasionally appearing and disappearing from their breeding grounds (McCaskie et al. 1988; Martin 1973). Rosier et al. (2006) reported post-breeding dispersal ranging from 0.2 to 53 km for adult male burrowing owls in the Carrizo Plain (San Luis Obispo County).

Several years of year-round monitoring at Moffett Federal Airfield (Trulio 1994) and Mineta San José International Airport (Barclay 2007) show that the number of owls observed declines during the fall and winter months beginning in October and lasting into March. This information does not prove that owls actually leave during the winter (see banding summary below); they could be simply less visible, as shown by LaFever et al. (2008) and suggested by Thomsen (1971) and Coulombe (1971), because they spend more time in their burrows during the day. Trulio (1994) reported that the number of burrows used at Moffett Federal Airfield did not decline during the winter, suggesting owls are less visible during the winter months. In central California, burrowing owls occur only as winter visitors in some coastal areas that appear to contain suitable breeding habitat (California Natural Diversity Database 2009; Barclay unpublished data). Burrowing owls breeding north of California are believed to migrate south with some birds over-wintering in California (Coulombe 1971; Barclay et al. 2007).

Recoveries of burrowing owls banded in California are another source of information about the nature of owl migration and dispersal. The U.S. Geological Survey Bird Banding Laboratory records (through August 2003) contained 106 encounters of 4708 burrowing owls banded in California (Barclay et al. 2007). Seventy-five (71%) of these encounters occurred in the same 10-minute block of longitude and latitude where the owls were banded, and 27 (25%) occurred in the 10-minute block adjacent to where they were banded. Of the remaining four encounters of owls that were banded and recovered in California, all were less than 95 km from the block where they were banded (Barclay et al. 2007). Recoveries included four records of owls that were banded outside California (two in Idaho, one in Washington, one in British Columbia) and recovered in California. Two owls banded in California were encountered outside the state: an owl banded in June 1975 in coastal southern California (Orange County) was recovered in November 1975 at an unspecified location in Mexico; the other was banded in October 1965 in Orange County (in the same 10-minute block as the owl recovered in Mexico) and encountered two and a half years later (March 1968) in Nevada (Barclay et al. 2007).

There were 1615 burrowing owls banded in the San Francisco Bay area through 2003 (Barclay et al. 2007). Although there have been numerous sightings of color banded owls near the locations where they were banded, there have been no sightings or recoveries of these banded owls outside the Santa Clara Valley reported (through August 2003) to the Bird Banding Laboratory (Barclay et al. 2007). Four burrowing owls banded at San José International Airport have been encountered at NASA/Ames Moffett Federal Airfield approximately 7.5 miles away. These movements represent the longest distance movements of any of the over 700 burrowing owls banded at San José International Airport since 1993 (Barclay et al. 2007; Barclay unpublished data).

## Site Fidelity

Burrowing owls exhibit strong site fidelity and return to nest in the same areas year after year (Martin 1973; Bent 1938; Zarn 1974). Rosenberg and Haley (2004) reported that 85% of adults remained within 400 meters of the previous year's nest in the Imperial Valley. They observed that females tended to move greater distances between breeding seasons than males and distances were greater for owls that failed at nesting. Owls often nest in the same burrows in subsequent years, although Rich (1984) reported that they tend to occupy the same burrows for one to three years before moving to other burrows. Juvenile burrowing owls use satellite burrows during dispersal (Zarn 1974). Rosier et al. (2006) reported variable post-breeding dispersal of adult owls in the Carrizo Plain (San Luis Obispo Co.). Adults that failed at nesting tended to move greater distances, up to 53 km, than adults that were successful (Rosier et al. 2006).

74% of occupied burrows were reoccupied at Moffett Airfield between 1992 and 1994 (Trulio 1994). Burrowing owls at Moffett used many of the same or nearby (within eyesight) burrows year after year. Owls used 42 different burrows during this study. Seven (17%) burrows were used all three years, and 24 (57%) were used only two of the three years. Of the 11 burrows not reused, three were destroyed, two were only used during the early spring, and six were used for nesting only once.

Burrowing owls that have been intentionally relocated have generally shown strong fidelity to the sites from which they were moved. Feeney (1997) summarized the results of 14 relocations involving 104 owls that were relocated from 1–150 miles at different times of the year for various reasons. Owls tended to remain at or return to their original sites when the “relocation” consisted of closing occupied burrows (i.e., eviction). Owls transported to relocation sites tended to disappear from those sites shortly after release. Four birds relocated 48 km (30 miles) during the breeding season returned to their original sites the same day. Bloom et al. (2003), summarizing results of burrowing owl translocations in southern California, suggested well-planned, pre-breeding season translocations from breeding enclosures are probably the best long-term management tool.

Delevoryas (1997) reported on the active relocation of five pairs of owls at the beginning of the breeding season (February) in Santa Clara County. Four pairs of owls relocated 19 miles, kept in aviaries, and released in March nested on the relocation site. Two of the relocated pairs successfully raised young. Three females that experienced failed nesting attempts returned to the capture site. Six owls remained on the relocation site for one year, two were present two years later, and at least one owl was observed on the site four years later. Failure to maintain habitat in appropriate condition for burrowing owls may have contributed to owls dispersing from the relocation site (Delevoryas 1997).

**Table 4.** Movement Distances for Western Burrowing Owl

Type	Distance/Area	Location of Study	Citation
Home range (male)	May forage over 2–3 square km during nesting season	Saskatchewan	Haug and Oliphant 1987
	114 hectares	Imperial Valley, CA	Rosenberg and Haley 2004
Dispersal	Juveniles disperse about 0.6 km from natal burrows after fledging	Idaho	King and Belthoff 2001
	Adults disperse an average of 3.1 km (range 0.2–53 km)	Carrizo Plain, CA	Rosier et al. 2006
Migration	Highly variable, little data; Bay Area birds may be year-round residents		Haug et al. 1993; DeSante et al. 1997; Harman and Barclay 1997

## Ecological Relationships

In California western burrowing owls most commonly live in burrows created by California ground squirrels (*Spermophilus beecheyi*) (Gervais et al. 2008). Accordingly, the suitability and quality of burrowing owl habitat in the study area is closely and positively related to the occurrence and population health of ground squirrels in an area. Burrowing owls and ground squirrels can co-inhabit the same burrow systems, but the frequency with which this occurs has not been measured, and underground interactions have not been studied. Burrowing owls may compete incidentally with other predators such as coyotes, other owls and hawks, skunks, weasels, and badgers for rodents and a variety of insects (Rosenberg et al. 1998).

## Burrowing Owls and Development

Wesemann and Rowe (1987) and Millsap and Bear (2000) studied the relationship between burrowing owl density and reproduction along an urban development gradient in Cape Coral, Florida where development ranged from <2% to >80%. They found that burrowing owl density and productivity of successful nests increased until 45–60% of the landscape was developed, and above that level owl density and reproduction declined. Wesemann and Rowe (1987) attributed the increase in owl density up to the 60% development level to increased prey abundance on developed lots containing irrigated landscape vegetation. Above 60% development owl numbers declined even though prey abundance continued to increase. Wesemann and Rowe (1987) concluded that, above 60% development, factors not related to food availability such as disturbance, burrow destruction, pets, collisions with automobiles, and reduced open space contributed to declining owl numbers.

Analysis of the environment in terms of six basic habitat types (defined by classification of reflectance of a Landsat image, Buchanan 1996) around burrowing owl nesting locations in the Santa Clara Valley revealed there was an

average of 139.5 acres of burrowing owl habitat within 0.5 miles of 62 locations where owls nested in the Santa Clara Valley in 1991 (Albion Environmental, Inc. 2000a). This translates into about 28% burrowing owl habitat (as defined during image classification) in the area within 0.5 miles of known burrowing owl nests. This proportion of burrowing owl habitat would be a useful minimum threshold to consider when evaluating the suitability of candidate burrowing owl preserve lands. This threshold of habitat availability could indicate that parcels much less than 139.5 acres where burrowing owls nest may be useful candidates for preservation, as long as the minimum threshold of habitat availability around those parcels is present.

The relationship between burrowing owls and development in Florida may have operated in the northern Santa Clara Valley and contributed to higher burrowing owl numbers and densities when this portion of the valley was less developed. Recent trends in breeding burrowing owl numbers (Table 1) suggest the threshold of development has been passed. The relationship between burrowing owl numbers and development and open space suggest the best remaining opportunities for burrowing owl habitat management and preservation are in the northern portion of the plan area, where there is more open space in the baylands.

## Survival and Causes of Mortality

### Survival

Estimates of juvenile survival rates (i.e., during their first year of life) range from 0.12 (Lutz and Plumpton 1997) to 0.30 (Thomsen 1971). Adult survival rates have ranged from 0.42 (Johnson 1997) to 0.81 (Thomsen 1971). Rosenberg and Haley (2004) reported annual survival rates of 0.65 for males and 0.62 for females. The maximum known age of a wild burrowing owl is 11 years (Dunning 2001). Recoveries of owls banded in California include an owl that was banded as a nestling and found dead seven years later (1974–1981) after being hit by an aircraft (Barclay et al. 2007). There is little information on lifetime reproductive success (Haug et al. 1993).

### Causes of Mortality

Causes of mortality in burrowing owls include predation (by hawks, owls, badgers, foxes, domestic cats, and others (Bent 1938; Coulombe 1971; Green 1983; Haug et al. 1993), vehicular collisions, disease and parasites (Haug et al. 1993). Juvenile owls experience the greatest mortality (see above) during the post-fledging period (Clayton 1997). Vehicular collisions, which accounted for 25–60% of burrowing owl mortalities in three studies (summarized in Haug et al. 1993), are a significant cause of mortality because burrowing owls habitually perch and hunt on roadways at night (Bent 1938; Haug et al. 1993). Burrow destruction and other anthropogenic factors, especially during the breeding season, (e.g., agricultural and construction activity, disking, shooting, and pest control) also contribute to burrowing owl mortality (Zarn 1974; Thomsen 1971; Haug et al. 1993).

Some researchers have suggested that burrowing owls may be affected by secondary poisoning through ingestion of compounds used to control ground squirrels (Remsen 1978; Zarn 1974). Two studies of the effects of strychnine to control ground squirrels on predatory birds (Schmutz et al. 1989; James et al. 1990) did not document burrowing owl mortality due to strychnine. However, James et al. (1990) concluded that strychnine could have sublethal effects on burrowing owls. The potential for secondary poisoning of burrowing owls probably varies with the local prey base, the extent to which owls feed on the species being targeted for poisoning, and the type of control agents used. James and Fox (1987) reported lower productivity and possible direct mortality of owls exposed to carbofuran pesticide used to control grasshoppers in Saskatchewan.

## Population Status and Trends

**Global:** *Declining* (NatureServe 2006)

**State:** *Priority 2* ( Shuford and Gardali 2008)

**Within Study Area:** *Declining*

## Threats

The most immediate threats to the burrowing owl are the conversion of grassland habitat to urban and agricultural uses other than livestock grazing and the loss of suitable agricultural lands to development (Gervais et al. 2008). Equally important is the loss of fossorial rodents, such as ground squirrels, across much of the owl's historical range (Gervais et al. 2008). Eradication programs have decimated populations of these rodents and have in turn disrupted the ecological relationships on which owls depend; because western burrowing owls typically need other animals to dig their burrows, the loss of fossorial rodents limits the extent of year-round owl habitat throughout their range (Haug et al. 1993).

## Data Characterization

As of July 2009, there were 53 occurrences of burrowing owls in Santa Clara County in the California Natural Diversity Database (2009). Existing information, including surveys for nesting owls in the plan area in 2008 (Albion Environmental, Inc. 2008a) should be sufficient to evaluate the population status of this species in the planning area; however, much of the HCP/NCCP planning area includes private lands that have not been surveyed systematically for this species.

## Existing Conservation Actions in the Study Area

The City of San José prepared a draft burrowing owl habitat conservation strategy and implementation plan in 2000 (Albion Environmental, Inc. 2000a), but the City Council did not adopt it. The City of San José passed a disking ordinance (Chapter 9.54) in 2000 prohibiting disking in most of the city. Mineta San José International Airport has been implementing a burrowing owl management program since the mid-1990s (Barclay 2007).

In 2003, the City of Morgan Hill adopted a citywide burrowing owl habitat mitigation plan. In October 2003, the also city adopted an ordinance making it unlawful for anyone to disk, plow, or otherwise break into or turnover soil on any property within the city if the land meets certain criteria for burrowing owl occupancy.

Most of the research studies emphasize nest site selection, passive relocation, use of artificial burrows, reproductive success, dispersal, and foraging behavior. Common management efforts employed to conserve existing burrowing owl colonies include prevention of all disturbance during the nesting season, installation of permanent artificial burrows (Barclay 2007, 2008), and management of the vegetation around the burrows by mowing or controlled grazing.

Delevoryas (1997) reported on the active relocation of five pairs of owls at the beginning of the breeding season (February) in 1990 in Santa Clara County. Four pairs of owls relocated 19 miles, kept in aviaries, and released in March nested on the relocation site. Two of the relocated pairs successfully raised young. Three females that experienced failed nesting attempts returned to the capture site. Six owls remained on the relocation site for one year, two were present two years later and at least one owl was observed on the site four years later. Failure to maintain habitat in appropriate condition for burrowing owls may have contributed to owls dispersing from and not returning to the relocation site (Delevoryas 1997).

## Burrowing Owl Conservation and Management Activities

Burrowing owl conservation and management have been the subjects of several plans spanning a broad spatial scale from continental to regional to site-specific. These include the tri-national North American Conservation Action Plan for the Western Burrowing Owl (Commission for Environmental Cooperation 2005), the Status Assessment and Conservation Plan for the Western Burrowing Owl in the United States (Klute et al. 2003), Recovery Strategy for the Burrowing Owl (*Athene cunicularia*) in Canada (Environment Canada 2007), Recovery Plan for the burrowing owl in Canada (Hjertaas 1997), and Effects of management practices on grassland birds: burrowing owl (Dechant et al. 1999). The California Department of Fish and Game is preparing a Conservation Strategy for burrowing owls in California (Burkett and Johnson 2007).

Concern about range-wide declines of western burrowing owl populations in many areas was the impetus for three International Burrowing owl Symposia; the first in 1992 (Lincer and Steenhoff 1997), the second in 1998 (Wellicome and Holroyd 2001), and the third in 2006 (no proceedings). A California Burrowing Owl Symposium (Barclay et al. 2007) was convened because of concern about declines in California.

Efforts to manage burrowing owls have employed a variety of techniques to address site-specific goals and conditions. Common management activities have addressed habitat management on preserve lands (Albion Environmental, Inc. 2004; Johnson 1986; Stanton and Teresa 2007), evaluation of impacts from development projects (Albion Environmental, Inc. 1997, 1999; Bendix 2007; Smith and Belthoff 2001; Trulio 2001), prevention of disturbance during the nesting season (Koshear et al. 2007), installation of artificial burrows (Collins and Landry 1977; Poulin 2000; Smith and Conway 2005; Smith et al. 2005; Barclay 2008), and management of burrowing owls on military installations and airfields (Albion Environmental, Inc. 2008b, Barclay 2007; Garcia and Conway 2007; Rosenberg et al. 1998; Trulio 2001).

The reintroduction of burrowing owls into vacant range has been done with limited success in British Columbia (Munroe et al. 1984; Leupin and Lowe 2001), Manitoba (De Smet 1997) and Minnesota (Martell et al. 2001), and on a small experimental scale locally in the Coyote Valley (Delevoryas 1997).

Management practices have also been implemented to address the unwanted occurrence of burrowing owls in some settings. These include passive relocation (Trulio 1995; Bendix 2007) and active relocation (Feeney 1997; Bloom et al. 2003) to address the occurrence of owls in development projects (Smith and Belthoff 2001) and avoid direct impacts (i.e., take). Management has also been designed to address predation of burrowing owls on other special-status species (Garcia and Conway 2007).

**Table 5.** Conservation Actions in the Study Area for Western Burrowing Owl

Action	Timing	Lead Agency	Location
Burrowing owl mitigation program	On-going	San José International Airport	San José
Burrowing owl habitat mitigation program and ordinance	On-going	City of Morgan Hill	Morgan Hill
Burrowing owl mitigation program	Being considered by staff	City of San José	San José

## Modeled Species Distribution in Study Area

### Model Description

#### Model Assumptions

##### Occupied Nesting Habitat

Occupied nesting includes sites occupied within the previous 3 years that are surrounded by at least 140 acres of foraging habitat within 0.5 mile of the nest site. The 140 acres parameter was mapped based on aerial photo analysis of known occupied nest sites.

##### Potential Nesting Habitat

Any grassland, agricultural, or barren land cover types that are located outside of the 0.5 mile radius around occupied nest sites, and inside of one of the burrowing owl conservation zones shown in Figure 2.

##### Overwintering Only Habitat

All annual grassland, serpentine bunchgrass grassland, valley oak woodland, agricultural, and barren land cover types with flat (0–5%) or moderate (5–25%) slopes, outside of one of the burrowing owl conservation zones shown in Figure 2.

### Rationale

#### Occupied Nesting Habitat

In the late 1990s the City of San José (2000) studied all extant burrowing owl nest locations within San José and surrounding environs, and discovered that there was an average of 140 acres of suitable habitat (out of a total of approximately 503 total acres) within 0.5 mile (i.e., the typical foraging distance). The number of breeding pairs at each colony (one or more nesting pairs located in relatively close proximity) varied from one to many. Due to the urbanized and fragmented landscape in San José, it is assumed that the available habitat supports more breeding pairs than found in burrowing owl populations away from urbanized areas.

Based on these studies, the Plan assumes that in order to remain viable, a nesting location needs to be accompanied by at least 140 acres of essential foraging habitat within 0.5 mile. The same habitat could support multiple pairs. This clumping of nesting pairs (colonies) can be observed at any of the breeding colonies in the South San Francisco Bay Area (i.e., San José International Airport, Moffett Federal Airfield, and San José/Santa Clara Water Pollution Control Plant).

Occupied burrowing owl nesting habitat modeled for the Plan is comprised of two components, a specific location containing one or more active nests, and the essential foraging habitat that supports the nest or nests. Because owls tend to re-use sites, if a burrowing owl nest site has been confirmed on a parcel at any point during the previous 3 years, then that parcel is considered a burrowing owl nest location. Based on the known propensity of burrowing owls to forage within 0.5

mile of nest sites during the breeding season (Haug and Oliphant 1990; Rosenberg and Haley 2004), essential burrowing owl foraging habitat is defined as the parcel where the documented burrowing owl nest location is located and all parcels with undeveloped, grassland or barren land, within 0.5 mile of the nest location. If any portion of a parcel with suitable foraging habitat falls within 0.5 mile, the entire parcel is considered essential foraging habitat.

To confirm the current location of nest sites a survey was commissioned in 2008, with a focused follow up in 2009, to determine the number of viable breeding locations and to estimate the number of burrows that currently support a breeding pair in the study area. Burrowing owls were only documented in five locations within the study area (Albion Environmental Inc. 2008). All of those locations were within the urban service area of the City of San José. The highest concentration of nesting burrowing owls occurred in the northern part of the study area, at the San José International Airport, the San José/Santa Clara Water Pollution Control Plant and adjacent lands, and at the VTA Cerrone bus yard. One additional pair was located in southeastern San José (Albion Environmental Inc. 2008).

### **Potential Nesting Habitat**

Open grassland or barren lands on the valley floor that are outside of a 0.5 mile radius of occupied nest sites could potentially be successfully colonized by nesting burrowing owls in the future as long as there are no limiting factors associated with those lands. These are areas where burrowing owls have not been documented nesting in the recent past but where habitat conditions are such that individuals could successfully colonize in the future.

### **Overwintering Only Habitat**

Western burrowing owls typically occur in dry, open, shortgrass, treeless plains often associated with burrowing mammals (Haug et al. 1993). Golf courses, cemeteries, road allowances within cities, levees, and ruderal borders around agricultural fields, airports, and vacant lots in residential areas are also used for breeding, foraging, and overwintering. Within the study area annual grassland, serpentine bunchgrass grassland, valley oak woodland, and barren natural communities represent these habitats. Burrowing owls are also known to use the margins of agricultural areas, or even occasionally using the whole field when it is fallow and ground squirrels are allowed to colonize.

## **Model Results**

Figure 2 shows modeled occupied nesting, potential nesting, and overwintering only habitat for the western burrowing owl within the study area. Burrowing owl may overwinter within areas modeled as occupied or potential nesting, but they are unlikely to nest in overwintering only modeled habitat. Suitable habitat is spread widely throughout the valley floor and along the edge of the foothills that border the valley on both sides. Most known occurrences fall within modeled habitat. Some suitable habitat in developed areas may not show up in the output because it cannot be distinguished at this mapping resolution. These are typically small vacant lots or the margins of other land cover types.

**Figure 2**  
**Burrowing Owl Modeled Habitat Distribution - Santa Clara Valley Habitat Plan**

## Least Bell's Vireo (*Vireo bellii pusillus*)

### Legal Status

**State:** Endangered

**Federal:** Endangered, Migratory Bird Treaty Act

**Critical Habitat:** Designated (1994)

**Recovery Planning:** U.S. Fish and Wildlife Service 1998

**Notes:** No anticipated change in status during permit period.

### Taxonomy

There are four recognized subspecies of Bell's vireo (*Vireo bellii*) including *V. b. belli*, *V. b. medius*, *V. b. arizonae*, and *V. b. pusillus*, the least Bell's vireo (American Ornithologists' Union 1957). While all subspecies are similar in appearance, least Bell's vireos are mostly gray above and pale below, while easternmost birds are greenish above and yellowish below. Southwestern subspecies are intermediate in plumage characteristics. The least Bell's vireo in California is slightly larger than Bell's vireos in Arizona or Texas (Brown 1993). Descriptions of the species' physical characteristics, behavior, and distribution are provided in a variety of field guides (e.g., Sibley 2000; National Geographic 2002; Peterson 1990).

### Distribution

#### General

The Bell's vireo is a migratory species that breeds in North America and overwinters primarily along the Pacific Coast in southern Mexico. Breeding range for Bell's vireo is from north central to southwestern United States and into central Mexico. Breeding has been documented from southwestern California and northwestern Baja California, Mexico, to central South Dakota, east to Illinois and northwestern Indiana, south to the gulf coast and into southern Sonora, Mexico. Breeding in California usually takes place in southwestern California and northwestern Baja California, Mexico. However, recently (1997 and 2001) breeding individuals been reported as far north as southern Santa Clara County along Llagas Creek (Santa Clara Valley Water District 2002, California Natural Diversity Database 2006) (Figure 1). Additional sightings have occurred in southeastern Monterey County (Roberson 2004) and western Merced County. A successful breeding pair has also been documented in 2005 and 2006 in neighboring Stanislaus County, returning to this county for the first time in 40 years (U.S. Fish and Wildlife Service 2005). These sightings corroborate the notion that this species may be expanding back into its historical range.

## Occurrences within the Study Area

### Historical

Historically the breeding range of this species was widespread throughout California, including the Sacramento and San Joaquin Valleys (Grinnell and Miller 1944; U.S. Department of the Interior 1986). Santa Clara County's first record was of a nest with eggs collected by W.E. Unglish on 19 Apr 1932 in a dense willow thicket along the Pajaro River near Sargent (Unglish 1937).

### Recent

One to two individuals were observed during a May 1997 survey along Llagas Creek between Highway 152 and the Pajaro River confluence, east of Gilroy, and a nest was found (Santa Clara Valley Water District 2002; California Natural Diversity Database 2006; Bousman 2007). Subsequent visits were not made to determine whether the nest was successful. In this same area, three adults were observed during surveys in May 2001, but no nests were found. The site has been revisited in subsequent years, and no individuals have been detected (Santa Clara Valley Water District 2002, 2003, 2004). However, the SCVWD has been unable to survey the reaches with the most suitable habitat because they are under private ownership (Padley pers. comm.). Dense riparian corridors (sufficient overstory with a thick shrub understory) have been identified in other waterways in southern Santa Clara County, but no least Bell's vireos have been detected by the SCVWD (Santa Clara Valley Water District 2002, 2003, 2004). In June 2006 a singing Bell's vireo was seen along Coyote Creek near the Coyote Creek Golf Club (South Bay Birders Unlimited 2006). The bird was seen singing but no additional breeding behavior was observed (Mammoser pers. comm.). The extent of this species' range in the study area is not well understood (Figure 2).

## Natural History

### Habitat Requirements

Least Bell's vireo is known to nest in riparian woodlands dominated by willow (Peterson et al. 2004) and Fremont's cottonwood (Kus 2002b). Suitable willow woodlands are typically dense with well-defined vegetative strata or layers. The most critical structural component of nesting habitat in California is a dense shrub layer 2–10 feet (0.6–3.0 meters) above ground (Goldwasser 1981; Franzreb 1989, Brown 1993). Individuals may forage in adjacent scrub or chaparral habitat (U.S. Fish and Wildlife Service 1986). During the winter, the least Bell's vireo utilizes scrub vegetation adjacent to watercourses or riparian gallery forests along the west coast of northern and central Mexico (Hutto 1980).

**Table 1.** Habitat Associations for Least Bell's Vireo

Land Cover Type	Land Cover Use	Habitat Designation	Habitat Parameters	Rationale
Riparian woodland	Breeding, foraging	Primary	Typically riparian woodland dominated by willow shrubs and other thick understory vegetation	Goldwasser 1981; U.S. Fish and Wildlife Service 1986
Riparian scrub	Breeding, foraging	Primary	Typically riparian scrub dominated by willow and other thick vegetation	Goldwasser 1981; U.S. Fish and Wildlife Service 1986

## Reproduction

Breeding least Bell's vireos begin arriving on their breeding grounds in late March and begin nesting in early April (Kus 2002a). Individuals may remain on the breeding grounds into early October, but nesting is typically finished by the end of July (Kus 1999). Most pairs are monogamous during the breeding season (Brown 1993). Several factors may have an effect on breeding success including development adjacent to riparian habitat, brown-headed cowbird (*Molothrus ater*) parasitism, and water management.

**Table 2.** Key Seasonal Periods for Least Bell's vireo

	Jan	Feb	Mar	April	May	June	July	Aug	Sep	Oct	Nov	Dec
Breeding				✓	✓	✓	✓					
Migration		✓	✓	✓				✓	✓	✓		
Wintering	✓	✓								✓	✓	✓

Sources: Brown 1993; Kus 1999, 2002a.

## Movement

Little is known about the migratory routes of this species. Individuals leave the northernmost breeding grounds by August or September (Barlow 1962). Most have left the U.S. by early October, although some may remain in the Lower Colorado River Valley until late November (Brown 1993). During spring migration, adults return to their breeding grounds in early to mid-March and reach the northern limits of the breeding range in May (Brown 1993; Kus 1999). Home range and movement during the breeding season is limited to areas within dense riparian corridors. Territories are often linear in nature, following the stream course. Size of home ranges is dependent on the quality of breeding habitat available and the number of breeding individuals that the area will support.

**Table 3.** Movement Distances for Least Bell's Vireo

Type	Distance/Area	Location of Study	Citation
Home Range	1.2 acres (0.5 ha)	Kansas	Barlow 1962
	0.5–4 acres (0.2–1.6 ha)	California	Gray and Greaves 1984
	0.7 ha	California	Collins et al. 1989
Dispersal	33 feet (10m) on day 1 to 330 feet (100m) on day 5	Indiana	Hensley 1950
	100–200 feet (30–60m) on day 14		Nolan 1960
Migration	From breeding grounds to Pacific Coast of southern Mexico	North America	Brown 1993

## Ecological Relationships

For successful breeding, this species is dependent on dense riparian corridors, typically along watercourses. Scrub habitats adjacent to these watercourses are equally important to the success of the species because they provide foraging opportunities as well as protection for nesting habitat. Brown-headed cowbirds have decimated Bell's vireo populations throughout its breeding range and this subspecies is no different. Dense riparian breeding habitat that is surrounded by agricultural lands or developed areas will facilitate brown-headed cowbird abundance and lower the breeding success of riparian nesting species like the least Bell's vireo.

## Population Status and Trends

**Global:** *Declining* (Kus 2002a; Peterson et al. 2004; NatureServe 2005)

**State:** *Declining in general but recent evidence of range extensions in San Joaquin Valley*

**Within Study Area:** *Unknown, may be increasing*

Due to extensive alteration of riparian corridors and adjacent habitats throughout its range, this subspecies has increasingly limited breeding habitat. Although populations have shown signs of increased range in California, numbers throughout North America are in decline. At its low point in the early 1980s, the California breeding population of the Least Bell's Vireo was estimated at only 300 pairs. Since the species was listed as endangered under the California endangered Species Act in 1980, and under the federal Endangered Species Act in 1986, riparian habitat restoration and cowbird trapping have resulted in considerable increases in Bell's Vireo population in southern California, which now exceed 1,300 pairs (U.S. Fish and Wildlife Service 1998). The species may be expanding its range northward in California to now include Santa Clara County. Consistent breeding locations will need to be documented in Santa Clara County to confirm a range expansion into the study area.

## Threats

Loss of breeding habitat due to watercourse alteration (e.g., channelization, urbanization and firewood cutting) is threatening the viability of this subspecies. In addition, nest parasitism by the brown-headed cowbird has greatly reduced nest success throughout most of its breeding range. An increase in cowbird abundance is propagated by particular land use practices (e.g., residential development, agriculture, grazing) on lands adjacent to breeding habitats (Kus 1999; NatureServe 2005).

## Data Characterization

Little is known about the occurrence of this subspecies within the inventory area, aside from the recent observations along Llagas Creek. Due to ongoing monitoring efforts along waterways in southern Santa Clara County, potential habitat for this species has been identified, and surveys for breeding pairs are underway. Although this species is rare in Santa Clara County, it is possible that it could expand its range northward during the permit period.

## Existing Conservation Actions in the Study Area

The Santa Clara Valley Water District (SCVWD) has conducted surveys for least Bell's vireo on Llagas Creek since 1997. Starting in 2005 the SCVWD began surveys for least Bell's vireo on Llagas Creek, Pajaro River, and Uvas Creek under its Stream Maintenance Program. Restoration efforts by the SCVWD and other groups like the Fisheries and Aquatic Habitat Collaborative Effort may benefit this subspecies.

## Modeled Habitat Distribution in Study Area

### Model Description

#### Model Assumptions

##### Primary Habitat—Breeding and Foraging

Breeding and foraging is limited to all riparian land cover types, including central California sycamore alluvial woodland, in the Pacheco Creek/Uvas Creek/Llagas Creek and Pajaro River watersheds in southern Santa Clara County. Though dense riparian corridors may exist in other parts of the study area, the suitable habitat model is limited to areas where the species has been documented in the recent past.

## Rationale

Although this species nested along heavily vegetated watercourses and associated scrub habitats throughout California, there are no known historical occurrences in Santa Clara County (Grinnell and Miller 1944). However, during a June 1997 survey along Llagas Creek east of Gilroy, a nest was found (Santa Clara Valley Water District 2002; California Natural Diversity Database 2006). During follow-up surveys in 2001, individuals were detected, but nesting was not confirmed. A similar trend has been reported from counties just south and east of Santa Clara County, so it is likely that this species will extend its range over time. However, with the limited survey information available on suitable habitat in southern Santa Clara County and only these two recent occurrences, we are limiting the suitable habitat to the southern portion of the study area.

## Model Results

Figure 2 shows the modeled potential habitat for the least Bell's vireo within the study area. The primary habitat for this species is characterized by well-developed riparian habitat and the modeled habitat corresponds to those land cover types. Due to the limited number of occurrences by the species in the study area determining the accuracy of the model is difficult. However, the known breeding occurrence in the study area does fall within the modeled habitat.

**Figure 1**  
**Least Bell's Vireo (*Vireo bellii pusillus*)**  
**Distribution in California**

This map presents outcomes of a model that is described in the species accounts of the Habitat Plan (Appendix D). Model limitations are described in Chapter 3. The purpose of the model is to identify areas within the study area where the species occurs or could occur based on known habitat requirements. The data on which this map is based are regional in scale. This map should not be used for site planning and should be verified in the field. Occurrence data are limited by where field surveys have been conducted; some occurrence points may be geographically inaccurate. See Chapter 3 for occurrence record sources.

**Figure 2**  
**Least Bell's Vireo Modeled Habitat Distribution - Santa Clara Valley Habitat Plan**

## Tricolored Blackbird (*Agelaius tricolor*)

### Legal Status

**State:** Bird Species of Special Concern; meets requirements as a rare, threatened or endangered species under the California Environmental Quality Act (CEQA)

**Federal:** Species of Concern; Migratory Bird Treaty Act

**Critical Habitat:** N/A

**Recovery Planning:** N/A

**Notes:** Change in status during permit period is uncertain

### Taxonomy

Tricolored blackbirds are endemic to the west coast of North America and primarily to California. Though individuals move and utilize different habitats within the region, depending on time of year, long distance migration has not been verified in this species. Banding studies by Neff (1942), DeHaven and Neff (1973), and DeHaven et al. (1975b) indicated that banding returns from tricolored blackbird (*Agelaius tricolor*) populations breeding in southern California from Santa Barbara County south to Baja California and east to the Sonoran desert were not from outside of this area. Songs of male tricolored blackbirds are not regionally distinguishable, unlike those of some red-winged blackbird populations in California (Collier 1968). No subspecies are currently recognized (American Ornithologists Union 1957; Pyle 1997). Descriptions of the species' physical characteristics, behavior, and distribution are provided in a variety of field guides (e.g., Peterson 1990; Sibley 2000; National Geographic 2002).

### Distribution

#### General

Tricolored blackbirds are largely endemic to California, and more than 99% of the global population occurs in the state (Beedy and Hamilton 1999). In any given year, more than 75% of the breeding population can be found in the Central Valley (Hamilton 2000). Small breeding populations also exist at scattered sites in Oregon, Washington, Nevada, and the western coast of Baja California (Beedy and Hamilton 1999) (Figure 1).

The species' historical breeding range in California included the Sacramento and San Joaquin Valleys, lowlands of the Sierra Nevada south to Kern County, the coast region from Sonoma County to the Mexican border, and sporadically on the Modoc Plateau (Dawson 1923; Neff 1937; Grinnell and Miller 1944).

## Occurrences within the Study Area

### Historical

Tricolored blackbirds have been present consistently in Santa Clara County, though their distribution has remained sporadic and ephemeral. A summary of early documentation of the species is summarized by Bousman (2007). Reports about the distribution of this species in Santa Clara County during the 20<sup>th</sup> century were of a rare and uncommon resident and included only occasional reports of small local colonies (Bousman 2007). During data collection for the Santa Clara County Breeding Bird Atlas from 1987–1993, tricolored blackbirds were recorded in 29 (17%) of atlas blocks, and breeding was confirmed in 15 of those blocks (Bousman 2007). In 1989 three colonies were documented in the county. These colonies ranged from 200–700 breeding individuals. Colony nest success was unknown for two of the colonies, and the third was abandoned in late April (California Natural Diversity Database 2006).

### Recent

There are a few documented colonies within the study area and perhaps others that have gone undocumented. In 1996, a colony of 300–500 individuals was documented just outside the study area in the San Antonio Valley, but colony success was unknown (California Natural Diversity Database 2006). During a 2004 survey coordinated by the Central Valley Bird Club, the one historical occurrence of breeding tricolored blackbirds within the county did not support a colony (Green and Edson 2004). In 2006, a breeding colony of approximately 200 individuals was documented within the city limits of Morgan Hill (T. Rahmig pers. obs.). That colony was smaller in 2007 (~150 individuals) and absent during a 2008 statewide survey coordinated by California Audubon (B. Powers pers. comm.).

Tricolored blackbirds are considered “itinerant breeders” (i.e., nomadic breeders) where individuals or colonies can breed in different regions within the same year (Hamilton 1998; Hamilton 2004). Because this species wanders considerably during the breeding season, individuals could successfully breed within the study area if suitable breeding and/or foraging habitat were available. Breeding colonies of tricolored blackbirds often go unreported because of their similar appearance to the common red-winged blackbird (*Agelaius phoeniceus*).

## Natural History

### Habitat Requirements

Tricolored blackbirds have three basic requirements for selecting their breeding colony sites: open, accessible water; a protected nesting substrate, including either flooded, thorny, or spiny vegetation; and a suitable foraging space providing adequate insect prey within a few miles of the nesting colony (Hamilton et al. 1995; Beedy and Hamilton 1997, 1999). Almost 93% of the 252 breeding colonies reported by Neff (1937) were in freshwater marshes dominated by cattails and bulrushes (*Schoenoplectus* spp.). The remaining colonies in Neff's study were in willows (*Salix* spp.), blackberries (*Rubus* spp.), thistles (*Cirsium* and *Centaurea* spp.), or nettles (*Urtica* spp.). In contrast, only 53% of the colonies reported during the 1970s were in cattails and bulrushes (DeHaven et al. 1975a).

An increasing percentage of tricolored blackbird colonies in the 1980s and 1990s were reported in Himalayan blackberries (*Rubus discolor*) (Cook 1996), and some of the largest recent colonies have been in silage and grain fields (Hamilton et al. 1995; Beedy and Hamilton 1997; Hamilton 2000). Other substrates where tricolored blackbirds have been observed nesting include giant cane (*Arundo donax*), safflower (*Carthamus tinctorius*) (DeHaven et al. 1975a), tamarisk trees (*Tamarix* spp.), elderberry/poison oak (*Sambucus* spp. and *Toxicodendron diversilobum*), and riparian scrublands and forests (e.g., *Salix*, *Populus*, *Fraxinus*) (Beedy and Hamilton 1999).

Ideal foraging conditions for tricolored blackbirds are created when shallow flood-irrigation, mowing, or grazing keeps the vegetation at an optimal height (<15 cm) (Tricolored Blackbird Working Group 2007). Preferred foraging habitats include agricultural crops such as rice, alfalfa, irrigated pastures, and ripening or cut grain fields (e.g., oats wheat, silage, and rice), as well as annual grasslands, cattle feedlots, and dairies. Tricolored blackbirds also forage in remnant native habitats, including wet and dry vernal pools and other seasonal wetlands, riparian scrub habitats, and open marsh borders (Tricolored Blackbird Working Group 2007).

**Table 1.** Habitat Associations for Tricolored Blackbird

Land Cover Type	Land Cover Use	Habitat Designation	Habitat Parameters	Rationale
Wetland	Breeding	Primary	Cattails, bulrushes, willows, Himalayan blackberries (recent shift), thistles, nettles, and other spiny or thorny plants	Beedy and Hamilton 1999
Riparian	Breeding	Primary	Riparian woodland and scrub	Beedy and Hamilton 1999
Agricultural	Foraging	Secondary	Open pastures, silage, grain fields, mowed alfalfa, pastures, dairies	Beedy and Hamilton 1999
Herbaceous dominated	Foraging	Secondary	Native and nonnative annual grasslands	Beedy and Hamilton 1999

## Reproduction

Tricolored blackbirds are closely related to red-winged blackbirds, but the two species differ substantially in their breeding ecology. Red-winged blackbird pairs defend individual territories, while tricolored blackbirds are among the most colonial of North American passerine birds (Bent 1958; Orians 1961a, 1961b, 1980; Orians and Collier 1963; Payne 1969; Beedy and Hamilton 1999). As many as 20,000 or 30,000 tricolored blackbird nests have been recorded in cattail marshes of 4 hectares (9 acres) or less (Neff 1937; DeHaven et al. 1975a), and individual nests may be built less than 0.5 meter (1.5 feet) apart (Neff 1937). Tricolored blackbird's colonial breeding system may have adapted to exploit a rapidly changing environment where the locations of secure nesting habitat and rich insect food supplies were ephemeral and likely to change each year (Orians 1961a; Orians and Collier 1963; Collier 1968; Payne 1969).

## Movement

During the breeding season, tricolored blackbirds exhibit itinerant breeding, commonly moving to different breeding sites each season (Hamilton 1998). In the northern Central Valley and northeastern California, individuals move after

their first nesting attempts, whether successful or unsuccessful (Beedy and Hamilton 1997). Banding studies indicate that significant movement into the Sacramento Valley occurs during the post-breeding period (DeHaven et al. 1975b).

During winter, virtually the entire population withdraws from Washington, Oregon (although a few remain), Nevada, and Baja California, and wintering populations shift extensively within their breeding range in California (Beedy and Hamilton 1999). Numbers of tricolored blackbirds decrease in the Sacramento Valley and increase in the Sacramento–San Joaquin River Delta and northern San Joaquin Valley (Neff 1937; Orians 1961a; Payne 1969; DeHaven et al. 1975b). By late October, large flocks also congregate in pasturelands in southern Solano County and near dairies on Point Reyes Peninsula in Marin County (Beedy and Hamilton 1999). Other birds winter in the central and southern San Joaquin Valley. Concentrations of more than 15,000 wintering tricolored blackbirds may gather at one location and disperse up to 32 kilometers (20 miles) to forage (Neff 1937; Beedy and Hamilton 1999). Individual birds may leave winter roost sites after less than three weeks and move to other locations (Collier 1968), suggesting winter turnover and mobility. In early March and April, most birds vacate the wintering areas in the Central Valley and along the coast and move to breeding locations in the Sacramento and San Joaquin Valleys (DeHaven et al. 1975b).

**Table 3.** Movement Distances for Tricolored Blackbird

Type	Distance/Area	Location of Study	Citation
Male territory (within colony)	20–35 square feet (0.8–3.25 m <sup>2</sup> )	California	Lack and Emlen 1939, Orians 1961a
Dispersal	33% recovered within 10 miles (16 km) of natal colonies	California	DeHaven et al 1975b
Home range	May range widely in flocks to over 9 miles (15 km) from active colony	California	Beedy and Hamilton 1999

## Ecological Relationships

Tricolored blackbirds occupy a unique niche in the Central Valley/coastal marshland ecosystems. In areas where the number of tricolored blackbirds is high, they are both aggressively and passively dominant to—and often displace—sympatric marsh nesting species, including red-winged and yellow-headed blackbirds (Orians and Collier 1963; Payne 1969). Recently, this species has been documented breeding in silage and rice fields in the Central Valley (Hamilton 2000, 2004).

## Population Status and Trends

**Global:** *Declining* (Beedy and Hamilton 1997, 1999)

**State:** *Declining* (Beedy and Hamilton 1997, 1999)

**Within Study Area:** *Unknown*

The U.S. Fish and Wildlife Service, the California Department of Fish and Game, and California Audubon cosponsored intensive tricolored blackbird surveys (carried out by volunteers in suitable tricolored blackbird surveys in suitable habitats throughout California) in 1994, 1997, 1999, 2000, and 2004 (Hamilton et al. 1995; Beedy and Hamilton 1997; Hamilton 2000, Green and Edson 2004). Local, regional, and statewide tricolored blackbird populations have experienced major declines since 1994. Statewide totals of adults in four late-April surveys covering all recently known colony sites were 369,359 (1994); 237,928 (1997); 104,786 (1999); 162,508 (2000), and >130,000 (low estimate for 2004). Several areas that historically supported large (>2,000 individuals) colonies in the central valley no longer have birds present (Green and Edson 2004; Hamilton 2004). The study area was not adequately surveyed during 2004, but the one historical location did not have any tricolored blackbirds present (Green and Edson 2004).

## Threats

The greatest threats to this species are the direct loss and alteration of habitat; however, other human activities, as well as predation, also threaten tricolored blackbird populations in the Central Valley (Beedy and Hamilton 1999). Most native habitats that once supported nesting and foraging tricolored blackbirds have been altered by urbanization and unsuitable agricultural uses, including vineyards, orchards, and row crops (Frayner et al. 1989; Wilen and Frayer 1990). Many former agricultural areas within the historical range of tricolored blackbirds are now being urbanized. Nests and nest contents in cereal crops and silage are often destroyed by agricultural operations (Hamilton et al. 1995; Beedy and Hamilton 1997). Harvesting of silage and plowing of weedy fields are currently the most common reasons that tricolored blackbird nesting colonies are destroyed in agricultural areas. Other factors that may affect the nesting success of colonies in agricultural areas include herbicide and pesticide applications, and spraying ponds for mosquito abatement (Beedy and Hamilton 1999). A primary reason for limited nesting success in agricultural areas (particularly in rice fields) is predation of fledgling by black-crowned night herons (*Nycticorax nycticorax*) (Hamilton 2004).

## Data Characterization

Statewide surveys were conducted for tricolored blackbirds in California in 1994, 1997, 1999, 2000, and 2004 (Hamilton et al. 1995; Beedy and Hamilton 1997; Hamilton 2000; Green and Edson 2004). Additional surveys include data on local distribution and population trends (Neff 1937; DeHaven et al. 1975a). Because this species is nomadic and exhibits erratic movement behavior, local

occurrence data provides only limited information on long-term small-area use patterns. This species forages and breeds in specific locations of the study area, largely freshwater marshes dominated by cattails or bulrushes, or in areas with suitable willow, blackberry, thistle, or nettle habitat (Beedy and Hamilton 1999).

A moderate amount of literature is available for the tricolored blackbird because it is a highly visible, colonial bird species commonly associated with wetland habitat. Beedy and Hamilton (1999) provide a comprehensive review of information available on general natural history, behavior, distribution and population changes, known demographics and population regulation, and conservation and management. A range-wide management plan was developed in 1997 (Beedy and Hamilton 1997) and the Tricolored Blackbird Working Group is currently developing a conservation plan that is scheduled for release in mid-2006.

## **Existing Conservation Actions in the Study Area**

There are no conservation actions occurring in the study area for tricolored blackbird. Management goals that have been proposed include maintaining a viable self-sustaining population throughout the species' current geographic range; avoiding losses of colonies and their associated habitats; increasing breeding populations on suitable public and private lands managed for this species; and enhancing public awareness and support for protection of habitat and active colonies.

Pond creation and restoration, though typically not initiated to benefit this species, could provide potential breeding habitat if tall dense vegetation (e.g., cattails) are allowed to establish.

A tricolored blackbird conservation plan was prepared by the Tricolored Blackbird Working Group in 2007 (Tricolored Blackbird Working Group 2007).

## **Modeled Species Distribution in Study Area**

### **Model Description**

#### **Model Assumptions**

##### **Primary Habitat—Breeding and Foraging**

Habitats suitable for breeding and foraging during the breeding season were modeled using all riparian woodland and scrub land-cover types, coastal and valley freshwater marsh and ponds within grassland, oak woodland, riparian forest/scrub, grain/row-crop/hay/pasture, and barren land-cover types.

**Secondary Habitat—Foraging and Wintering**

Areas that provide suitable foraging and wintering habitats include seasonal wetlands, all grasslands, and all agricultural land-cover types.

**Rationale**

Tricolored blackbirds historically occurred within the Central Valley associated with emergent freshwater marshes dominated by cattails or bulrushes, with some colonies occurring in willows, blackberries, thistles, and nettles associated with sloughs and natural channels (Neff 1937). More recent colonies have been observed in a diversity of upland and agricultural areas (Collier 1968; Cook 1996; Hamilton 2004), riparian scrublands and woodlands (Orians 1961a; DeHaven et al 1975a; Beedy et al. 1991; Hamilton et al. 1995; Beedy and Hamilton 1999).

Small breeding colonies have been documented at public and private lakes, reservoirs, and parks surrounded by shopping centers, subdivisions, and other urban development. Adults from these colonies generally forage in nearby undeveloped upland areas. Beedy and Hamilton (1999) predict that these small, urban wetlands and upland foraging habitats may continue to accommodate tricolored blackbirds in the future unless they are eliminated entirely by development. High-quality foraging areas include irrigated pastures, lightly grazed grasslands, dry seasonal pools, mowed alfalfa fields feedlots, and dairies (Beedy and Hamilton 1999). Lower quality foraging habitats include cultivated row crops, orchards, vineyards, and heavily grazed rangelands.

**Model Results**

Figure 2 shows the modeled potential habitat for the tricolored blackbird within the study area. Primary habitat is limited within the study area and it should be noted that by including all riparian areas the available breeding habitat is likely overestimated. Breeding habitat will actually be limited to small ponds/wetlands that occur in slow water portions of these riparian corridors. Secondary (foraging) habitat is prevalent throughout the valley floor and in the low elevations of the surrounding hills.

## San Joaquin Kit Fox (*Vulpes macrotis mutica*)

### Legal Status

**State:** Threatened

**Federal:** Endangered

**Critical Habitat:**

**Recovery Planning:** *Recovery*

*Plan for Upland*

*Species of the San Joaquin Valley, California*

(U.S. Fish and Wildlife Service 1998)

**Notes:** Status not anticipated to change during permit term.

Dr. Lloyd Glenn Ingles  
© California Academy of Sciences

### Taxonomy

The San Joaquin kit fox is a subspecies of the kit fox (*Vulpes macrotis*), the smallest member of the dog family in North America. Though there has been some debate as to the taxonomic relationship among North American arid land foxes, the San Joaquin kit fox remains a distinct subspecies due to its limited range in California. The details of this debate are outlined in Dragoo et al. (1990) and Schwartz et al. (2005). Descriptions of the species' physical characteristics can be found in McGrew (1979) and U.S. Fish and Wildlife Service (1998).

### Distribution

#### General

Currently, kit foxes occur in some areas of suitable habitat on the floor of the San Joaquin Valley and in the surrounding foothills of the Coast Ranges, Sierra Nevada, and Tehachapi Mountains from Kern County north to Contra Costa, Alameda, and San Joaquin Counties (U.S. Fish and Wildlife Service 1998) (Figure 1). There are known occurrences in Alameda, Contra Costa, Fresno, Kern, Kings, Madera, Merced, Monterey, San Benito, San Joaquin, San Luis Obispo, Santa Barbara, Santa Clara, Stanislaus, and Tulare Counties (California Natural Diversity Database 2006). The largest extant populations of kit fox are in Kern County (Elk Hills and Buena Vista Valley) and San Luis Obispo County in the Carrizo Plain Natural Area (U.S. Fish and Wildlife Service 1998).

## Occurrences within the Study Area

### Historical

Although the precise historical range of San Joaquin kit fox is unknown, it is believed to have extended from Contra Costa and San Joaquin Counties in the north to Kern County in the south. By the 1930s, the range had been reduced to the southern and western portions of the Central Valley (Grinnell et al. 1937). Surveys conducted between 1969 and 1975 extended the known range of the kit fox back into portions of its historical range in the northern San Joaquin Valley, including Contra Costa, Alameda, and San Joaquin Counties (Orloff et al. 1986). At this time, kit foxes were also found in three counties outside the originally defined historical range: Monterey, Santa Clara, and Santa Barbara counties (Orloff et al. 1986).

### Recent

There are four occurrences on record from 1972–2002 for the San Joaquin kit fox in Santa Clara County (California Natural Diversity Database 2006, U.S. Fish and Wildlife Service 2006). Of those records, two are based on observation of individuals and two are derived from San Joaquin kit fox range maps from 1972–1975. The two occurrences from the 1970's are not included here due to a lack of precision and because they are based on kit fox range maps and not actual observations. In 1992 a den site was found with two surviving pups (though the adult female had apparently been killed). The best description of the location of this den site is very general, stating that it is from Hollister north to Gilroy. It is included here simply as a placeholder and to acknowledge that habitat potential may exist in this area. The second observation (2002) was of a lone individual during the fall dispersal period in Henry Coe State Park (California Natural Diversity Database 2006). A third observation, which is not in the CNDDDB, was of a road kill kit fox over six miles south of the Highway 152/156 junction (U.S. Fish and Wildlife Service 2006). This occurrence falls just outside of the study area.

Genetic studies have shown that individuals from the San Luis Reservoir population, southeast of the study area, interbreed with individuals from Alameda and Contra Costa Counties (Schwartz et al. 2000 in U.S. Fish and Wildlife Service 2006). It is assumed (U.S. Fish and Wildlife Service 2006) that the Pacheco-Santa Ana watershed in the southeastern part of Santa Clara County provides movement habitat between these two areas. In the recovery plan for this species the U.S. Fish and Wildlife Service restricts the range in Santa Clara County to the Pajaro River watershed (U.S. Fish and Wildlife Service 1998).

## Natural History

### Habitat Requirements

San Joaquin kit foxes occur in a variety of habitats, including grasslands, scrublands, vernal pool areas, alkali meadows and playas, and an agricultural matrix of row crops, irrigated pastures, orchards, vineyards, and grazed annual grasslands (U.S. Fish and Wildlife Service 1998). They prefer habitats with loose-textured soils (Grinnell et al. 1937; Egoscue 1962) that are suitable for digging, but they occur on virtually every soil type. Dens are generally located in open areas with grass or grass and scattered brush, and seldom occur in areas with thick brush. Preferred sites are relatively flat, well-drained terrain (U.S. Fish and Wildlife Service 1998, Roderick and Mathews 1999). They are seldom found in areas with shallow soils due to high water tables or impenetrable bedrock or hardpan layers (O'Farrell and Gilbertson 1979; O'Farrell et al. 1980). However, kit foxes may occupy soils with a high clay content where they can modify burrow dug by other animals, such as California ground squirrels (*Spermophilus beecheyi*) (Orloff et al. 1986).

In the northern part of its range (including San Joaquin, Alameda, and Contra Costa Counties) where most habitat on the valley floor has been eliminated, kit foxes now occur primarily in foothill grasslands (Swick 1973; Hall 1983; U.S. Fish and Wildlife Service 1998), valley oak savanna, and alkali grasslands (Bell 1994). Less frequently they occur adjacent to and forage in tilled and fallow fields and irrigated row crops (Bell 1994). These foxes will den within small parcels of native habitat that are surrounded by intensively maintained agricultural lands (Knapp 1978) and adjacent to dryland farms (Jensen 1972; Orloff et al. 1986; U.S. Fish and Wildlife Service 1998).

The diet of kit foxes varies, with season and geographic locality based on local availability of potential prey. In the northern portion of their range, kit foxes most commonly prey on California ground squirrels, cottontails (*Sylvilagus auduboni*), black-tail jackrabbits (*Lepus californicus*), pocket mice (*Perognathus* spp.), and kangaroo rats (*Dipodomys* spp.) (Hall 1983; Orloff et al. 1986; U.S. Fish and Wildlife Service et al. 1998). Secondary prey taken opportunistically may include ground-nesting birds, reptiles, and insects (Laughlin 1970).

**Table 1.** Habitat Associations for San Joaquin Kit Fox

Land Cover Type	Land Cover Use	Habitat Designation	Habitat Parameters	Rationale
Grassland	Breeding, foraging, movement	Primary	Requires suitable burrows for denning, primarily provided by ground squirrels in the northern portion of the kit fox geographic range. Must be managed to maintain low vegetation height	Low vegetation is thought to provide clear view of potential predators. Presence of burrowing species provides burrows for refugia and a substantial prey base.
Agricultural	Foraging and movement	Secondary, Movement	Improves with the presence of suitable prey.	Periodic disking renders this type of habitat as unsuitable for denning and for some prey species.

Sources: Orloff et al. 1986; U.S. Fish and Wildlife Service 1998.

## Reproduction

Kit foxes can, but do not necessarily, breed their first year. Sometime between February and late March, two to six pups are born per litter (Zoellick et al. 1987; Cypher et al. 2000). The annual reproductive success for adults can range between 20% and 100% (mean: 61%;) and 0 and 100% for juveniles (mean: 18%) (Cypher et al. 2000). Population growth rates generally vary positively with reproductive success and kit fox density is often positively related to both current and the previous year's prey availability (Cypher et al. 2000). Prey abundance is generally strongly related to the previous year's effective (October to May) precipitation.

**Table 2.** Key Seasonal Periods for San Joaquin Kit Fox

Denning	✓	✓	✓							✓	✓	✓

Sources: U.S. Fish and Wildlife Service 1998; Koopman et al. 2000.

## Movement

Kit foxes may range up to 20 miles at night during the breeding season and somewhat less (6 miles) during the pup-rearing season (Girard 2001). The species can readily navigate a matrix of land use types. Home ranges vary from less than one square mile up to approximately 12 square miles (Knapp 1978;

Spiegel and Bradbury 1992; White and Ralls 1993). The home ranges of pairs or family groups of kit foxes generally do not overlap (White and Ralls 1993). This behavior may be an adaptation to periodic drought-induced scarcity in prey abundance.

**Table 3.** Movement Distances for San Joaquin Kit Fox

Type	Distance/Area	Location of Study	Citation
Home range	In some cases less than 1 m <sup>2</sup> (2.6 km <sup>2</sup> ) but generally approx. 2 m <sup>2</sup> (3.1 km <sup>2</sup> ) up to 12 m <sup>2</sup> (31.2 km <sup>2</sup> )	Multiple areas	Morrell 1972, Knapp 1978, Zoellick et al. 1987, Speigal & Bradbury 1992, White and Ralls 1993
Dispersal	Variable, 5.0±0.9 miles (8±1.4 km) up to ~74 miles	Elk Hills near Taft	Scrivner et al. 1987

## Ecological Relationships

San Joaquin kit foxes prey upon a variety of small mammals, ground-nesting birds, and insects. They are in turn subject to predation by such species as coyote, non-native red foxes, domestic dog, eagles, and large hawks (Hall 1983; Berry et al. 1987; Ralls and White 1995). White et al. (2000) determined that coyotes were responsible for 59% of kit fox deaths during a 4-year telemetry study at Camp Roberts in southern Monterey County.

## Population Status and Trends

**Global:** *Declining*

(NatureServe 2006; California Department of Fish and Game 2005)

**State:** *Same as above*

**Within Study Area:** *Unknown due to lack of data*

Although the San Joaquin kit fox is known to occur within the study area, information on the extent of its range is very limited (California Natural Diversity Database 2006). Compared with populations in the southern San Joaquin Valley, little is known about the ecology and habitat needs of kit foxes in the northern part of their range. Researchers have consistently indicated that the behavioral ecology of kit foxes in this region is poorly known and may be different from the ecology of foxes in the southern part of their range (Laughrin 1970; Swick 1973; Morrell 1975; Orloff et al. 1986; Sproul and Flett 1993; Bell 1994). The northern populations of kit foxes appear to use different prey (ground squirrels instead of kangaroo rats), and their denning habitat appears different (Orloff et al. 1986). In addition, habitat features such as ground cover, dominant vegetation, land use practices, rainfall, and in some cases slope, is substantially different in the north than in the south, where kit foxes are more abundant and well studied. Because of these differences, geographic differences may exist in

the demographic characteristics of these populations. However, the threats to the species are likely to be comparable in both regions of their range.

## Threats

Continued fragmentation of habitat is a serious threat to this species. Increasing isolation of populations through habitat degradation and barriers to movement, such as aqueducts and busy highways, can limit dispersal to and occupancy of existing and former lands. The threat of being struck by vehicles is high, particularly for dispersing individuals.

Habitat alteration also represents a threat to this species. This is known to result from oil extraction and mining activities, changes in wildlife prevalence, and changes in vegetation structure due to nonnative species and altered grazing regimes (U.S. Fish and Wildlife Service 2010). Livestock grazing is not thought to be necessarily detrimental to the kit fox (Morrell 1975; Orloff et al. 1986), but it may affect the number of prey species available, depending on the intensity of grazing (U.S. Fish and Wildlife Service 1998). Moderate grazing is thought to benefit the species because it can potentially enhance the prey base and reduce vegetation to allow kit fox to more easily detect and avoid predators. The use of pesticides to control rodents and other pests also threatens kit fox in some areas, either directly through poisoning or indirectly through reduction of prey abundance.

## Data Characterization

There are 16 occurrences on record from 1973–2004 for the San Joaquin kit fox in the three-county region that includes Santa Clara, Alameda, and Stanislaus Counties. Four of those records are within the HCP/NCCP study area but only two were verified. A moderate amount of literature is available for the San Joaquin kit fox because of its state threatened and federally endangered status. While numerous surveys have been conducted in the southern portion of the range, very few surveys or studies have been conducted within the northern portion of its range or in the study area. Quantitative data are available on population size, reproductive capacity, mortality, dispersal, home-range movement patterns, and habitat characteristics and requirements. A number of models have been developed to describe the species' population dynamics. Because there are few sightings within the HCP/NCCP study area and the area has been under surveyed, it is assumed that trends within the study area are consistent with those documented for the northern range of the species.

## Existing Conservation Actions in the Study Area

In 1998, a recovery plan for upland species of the San Joaquin Valley was completed (U.S. Fish and Wildlife Service 1998) that included a revised recovery strategy for the San Joaquin kit fox. The goal of this recovery plan is to maintain

a viable metapopulation of kit foxes on private and public lands throughout the plan's geographic range. No conservation areas were identified from within the HCP/NCCP study area for this species in the 1998 recovery plan or in a subsequent reserve design analysis for the entire range of the species (Haight et al. 2004). However, the recovery plan identifies the protection of existing kit fox habitat in the northern portion of its range and protection of existing connections between suitable habitat and primary recovery areas.

The Nature Conservancy's Mount Hamilton Project includes land preservation throughout the southeastern portion of the study area. One of their target species for conservation is the San Joaquin kit fox.

## Modeled Species Distribution in Study Area

### Model Description

Only movement and foraging habitat was identified within the study area for this species. It is denoted on Figure 2 as secondary habitat though this has been identified as a possible movement corridor between breeding populations.

### Model Assumptions

#### Secondary Habitat—Movement and Foraging

All grassland land cover types and seasonal wetlands and ruderal areas that are adjacent to grasslands were considered suitable movement and foraging habitat for this species. Further, valley oak/grasslands, blue oak woodland, and coast live oak woodlands within 500-feet of suitable grasslands were also considered suitable movement and foraging habitat. These parameters were only considered suitable habitat within the Pacheco and South Santa Clara Valley watersheds. Small fragments of habitat that were disconnected from contiguous habitat blocks were removed from the results to better represent actual movement potential for the species.

#### Secondary Habitat—Low-Use Movement

Areas that the San Joaquin kit fox may use occasionally for movement include orchards, golf courses/urban parks, and ruderal areas that are connected to movement and foraging habitat described above. These were intended to represent areas that individuals might pass through while moving between other more suitable habitat types.

### Rationale

In the northern part of its range the San Joaquin kit fox now occurs primarily in foothill grasslands (Swick 1973; Hall 1983; U.S. Fish and Wildlife Service 1998), valley oak savanna and alkali grasslands (Bell 1994). They prefer habitats

with loose-textured soils (Grinnell et al. 1937; Hall 1946; Morrell 1972), suitable for digging, but occur on virtually every soil type. It has been established that individuals from the San Luis Reservoir population interbreed with individuals from Alameda and Contra Costa Counties, north of the study area, leading experts to believe that southern Santa Clara County may be a movement corridor between these two areas. This habitat model was based on that assumption and habitat that is shown in Figure 2 should be considered low-use secondary habitat.

## Model Results

Figure 2 shows the modeled potential habitat of the San Joaquin kit fox within the Santa Clara Valley HCP/NCCP study area. The habitat includes only the southeastern portion of the study area and is primarily located on private lands south of Henry Coe State Park. Since there are so few documented occurrences of the kit fox from within the study area it is difficult to state what the accuracy of the model is relative to actual presence of the species.

# Tiburon Indian Paintbrush (*Castilleja affinis* ssp. *neglecta*)

## Legal Status

**State:** Threatened (California Department of Fish and Game 1990); California Native Plant Society 1B.<sup>1</sup>

**Federal:** Endangered (U.S. Fish and Wildlife Service 1995)

**Critical Habitat:** None

**Recovery Planning:** *Recovery Plan for Serpentine Soil Species of the San Francisco Bay Area* (U.S. Fish and Wildlife Service 1998)

© Stuart Weiss

## Taxonomy

Tiburon Indian paintbrush (*Castilleja affinis* ssp. *neglecta*) was first collected in 1925 by Katherine Brandegee and described as *Castilleja neglecta* by Zeile at that time (Jepson 1925). In the updated Jepson Manual (Hickman 1993), the species was reduced to subspecific status by Chuang and Heckard.

## Description

Tiburon Indian paintbrush is an herbaceous perennial traditionally placed in the figwort family (Scrophulariaceae). Paintbrush species are hemiparasites, obtaining a portion of their nutrients by parasitizing other plant species. Recent studies suggest that the genus *Castilleja* should be grouped with other parasitic and hemiparasitic plants in the Broomrape Family (Orobanchaceae) (Olmstead et al. 2001). The host plant for Tiburon Indian paintbrush is unknown.

## Distribution

### General

Tiburon Indian paintbrush (*Castilleja affinis* ssp. *neglecta*) is known from nine occurrences in Marin, Napa, and Santa Clara Counties (California Natural Diversity Database 2007, Stuart Weiss pers. comm.) (Figure 1). The range of the plant is approximately 30 miles (east-west) by 70 miles (north-south) (U.S. Fish and Wildlife Service 1995).

<sup>1</sup> 1B means rare, threatened, or endangered in California and elsewhere; 0.1 means seriously endangered in California

## Occurrences within the Study Area

### Historical

Both occurrences of Tiburon Indian paintbrush in the study area are presumed to be extant (California Natural Diversity Database 2007).

### Extant

The two populations of the species in Santa Clara County (occurrence #7 and #9) are found along Coyote Ridge north of Morgan Hill. One occurs on land owned by Santa Clara County Waste Management, and one occurs on land owned by Castle and Cook and leased by Santa Clara County Waste Management. These populations occur on 1/3 of a hectare of land within the Kirby Canyon area. The southern population (occurrence #7) is located on the top of Paintbrush Hill and on its northeast-facing slope. The northern population is located in North Canyon on a steep north-facing slope (occurrence #7 and #9) (Stuart Weiss pers. comm.). These two populations were recently recounted in 2006. It should be noted that occurrence #7 in the California Natural Diversity Database represents both the Paintbrush Hill and North Canyon populations, while occurrence #9 refers to the North Canyon population alone (Stuart Weiss pers. comm.; California Natural Diversity Database 2007). This latter population is by far the largest occurrence in all three counties in which the species is found.

## Natural History

### Habitat Requirements

Tiburon Indian paintbrush is a strict serpentine endemic species found in rocky serpentine bunchgrass communities between 250 and 1,300 ft in elevation (Safford et al. 2005; California Natural Diversity Database 2007).

Associated native plants can include California gilia (*Gilia achilleifolia* ssp. *multicaulis*), California melic (*Melica californica*), California poppy (*Eschscholzia californica*), dwarf plantain (*Plantago erecta*), foothill needlegrass (*Stipa* [*Nassella*] *lepida*), hayfield tarweed (*Hemizonia congesta* ssp. *congesta*), longhorn plectritis (*Plectritis macrocera*), purple needlegrass (*Stipa* [*Nassella*] *pulchra*), purple sanicle (*Sanicula bipinnatifida*), royal larkspur (*Delphinium variegatum* ssp. *variegatum*), and slender fairyfan (*Clarkia gracilis* ssp. *gracilis*). Rare species often found in occurrence with Tiburon Indian paintbrush include Santa Clara Valley dudleya (*Dudleya abramsii* ssp. *setchellii*), Marin dwarf-flax (*Hesperolinon congestum*), serpentine reedgrass (*Calamagrostis ophitidis*), Tiburon buckwheat (*Eriogonum luteolum* var. *caninum*), Tiburon jewelflower (*Streptanthus glandulosus* ssp. *niger*), fragrant fritillary (*Fritillaria liliacea*), and Mt. Hamilton thistle (*Cirsium fontinale* var. *campylon*) (U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2007). Non-native plants frequently found in association with Tiburon Indian paintbrush include Italian

ryegrass (*Festuca perennis* [*Lolium multiflorum*]), slender wild oat (*Avena barbata*), and soft brome (*Bromus hordeaceus*) (U.S. Fish and Wildlife Service 1998).

**Table 1.** Habitat Associations for Tiburon Indian Paintbrush

Land Cover Type	Habitat Designation	Habitat Parameters	Percent Suitable	Rationale
Serpentine bunchgrass grassland	N/A	Serpentinite soils, often rocky sites with low coverage of non-native species, on north- to west-facing slopes, 250–1,300 feet	Unknown	U.S. Fish and Wildlife Service 1995; California Natural Diversity Database 2007

## Population Ecology

The yellow flowers of Tiburon Indian paintbrush are hummingbird pollinated (Kevin Bryant pers. comm.). Seed dispersal occurs from June to October. The plant dies back to its woody base after seed dispersal and new growth occurs after the first winter rain. Seeds remain dormant in the soil until appropriate conditions occur, which can take several years (Martin 1989; U.S. Fish and Wildlife Service 1998). Germination may be induced by water (disintegrates the netted seed coat) and low temperatures (5 to 15 degrees Celsius or 45–59 degrees Fahrenheit) (Kevin Bryant pers. comm.; U.S. Fish and Wildlife Service 1998). Seedling establishment may be negatively affected by slow root growth, although the establishment and success of this plant is likely the result of several factors such as local climate, soils, and the amount of herbivory (Martin 1989; U.S. Fish and Wildlife Service 1998).

The size of the eight recorded populations are small (some under 100 individuals), with the largest population consisting of approximately 1,000 individuals at the North Canyon site in the Kirby Canyon area of Coyote Ridge in Santa Clara County (California Natural Diversity Database 2007; Stuart Weiss pers. comm.). The Kirby Canyon Butterfly Trust is now actively monitoring the populations in the Kirby Canyon area in order to obtain additional demographic and ecological information about the species (Stuart Weiss pers. comm.). Table 2 shows key life cycle periods for the Tiburon Indian paintbrush.

**Table 2.** Key Seasonal Periods for Tiburon Indian paintbrush (Kevin Bryant pers. comm.)

	Jan	Feb	March	April	May	June	July	Aug	Sep	Oct	Nov	Dec
Germination	✓	✓									✓	✓
Flowering				✓	✓	✓	✓					
Fruiting				✓	✓	✓	✓					
Seed Dispersal						✓	✓	✓	✓	✓		

## Population Status and Trends

**Global:** Stable

**State:** Stable

**Within Study Area:** Stable but need further study

All eight occurrences of Tiburon Indian paintbrush are presumed to be extant (California Natural Diversity Database 2007). Additional monitoring needs to be carried out to determine the true status of the populations both within and outside of the study area. In Marin, the Ring Mountain population (occurrence #4) was last checked in 2006 and appears to be in a steady-state condition, while the St. Hilary's population (occurrence #2) is very small and may be in decline (D. Herlocker pers. comm.).

## Threats

Population trends are uncertain, although they are likely to be stable, as the habitat in which they occur is rated fair to excellent (California Natural Diversity Database 2007). Potential threats include habitat loss through encroachment of residential development, proposed quarry expansion, herbivory by deer, trampling by dogs, foot traffic, soil slumping, competition from invasive exotic species, and disturbance from feral pig rooting (U.S. Fish and Wildlife Service 1995; California Natural Diversity Database 2007). The latter threat is especially a problem at the Paintbrush Hill site in Santa Clara County. Grazing is also listed as a threat, but may actually be beneficial in certain areas (Stuart Weiss pers. comm.).

## Data Characterization

Of the eight occurrences listed in the California Natural Diversity Database for Tiburon Indian paintbrush, five of these have been documented in the previous 10 years, and all have been documented within the last 19 years. All of these occurrences are believed to be extant; most are of high precision and may be accurately located.

There is still much to learn regarding the population ecology and demographics of Tiburon Indian paintbrush. The main sources of general information on the Tiburon Indian paintbrush are *The Jepson Manual* (Chuang and Heckard 1993), a master's thesis (Martin 1989), and the California Native Plant Society (2001). Specific observations on habitat and plant associates, threats, and other factors are found in the California Natural Diversity Database (2007) and in the Recovery Plan for Serpentine Soil Species of the San Francisco Bay Area (U.S. Fish and Wildlife Service 1998). Additional information can be found in the Final Rule listing the species as endangered (60 Federal Register 6671–6685, February 3, 1995).

## Existing Conservation Actions in the Study Area

In Santa Clara County, the northern population (North Canyon) of Tiburon Indian paintbrush is on privately owned land which Santa Clara County Waste Management may look to acquire and protect as a mitigation site for the Kirby Canyon Landfill. The southern population (Paintbrush Hill) is currently functioning as a mitigation site for the Landfill and is located on a reserve for bay checkerspot butterfly conservation (U.S. Fish and Wildlife Service 1998). Both populations are being monitored and managed by the Kirby Canyon Butterfly Trust, which plans to begin collecting seed from these populations in the near future. They are working on a way to reduce damage caused by feral pig rooting in the southern site while still maintaining cattle grazing, which appears to keep invasive non-native species in check (Stuart Weiss pers. comm.).

## Modeled Habitat Distribution in Study Area

A model was not developed for Tiburon Indian paintbrush because the serpentinite soils at the two Santa Clara occurrences appear to be unique and quite different than other serpentinite soils in the area.

© Janell Hillman

## Taxonomy

Coyote ceanothus (*Ceanothus ferrisiae* McMinn) is the accepted name for this species (Integrated Taxonomic Information System 2012). McMinn (1933) originally described the species based on specimens collected above Coyote Creek, along Madrone Springs Road. Coyote ceanothus is a member of the buckthorn family (Rhamnaceae).

## Description

Descriptions of the species' physical characteristics can be found in McMinn (1959), Munz and Keck (1959), Schmidt (1993), Corelli and Chandik (1995), and U.S. Fish and Wildlife Service (1998 and 2011). Coyote ceanothus is an erect evergreen shrub 1–2 m tall, with long spreading primary branches and short lateral branches (McMinn 1959). Its leaves are usually opposite and round, while the leaf margins are short-toothed to entire (Corelli and Chandik 1995). Its white flowers are in clusters and the seed capsules have three apical horns (U.S. Fish and Wildlife Service 1998).

## Distribution

### General

Coyote ceanothus is known from three occurrences in the Mt. Hamilton Range in Santa Clara County (Figure 1; U.S. Fish and Wildlife Service 2011). This species is endemic to California and is only found in Santa Clara County.

<sup>1</sup> 1B means rare, threatened, or endangered in California and elsewhere; 0.1 means seriously endangered in California.

## Occurrences within the Study Area

### Historical

There is one reported occurrence in Santa Clara County from Croy Canyon in 1929 (California Natural Diversity Database Occurrence #4). However, field surveys at the same locality in 1985 and 1987 failed to locate any plants (California Natural Diversity Database 2006). According to the U.S. Fish and Wildlife Service and the California Natural Diversity Database, the record may be erroneous (U.S. Fish and Wildlife Service 1998, California Natural Diversity Database 2006).

### Extant

The CNDDDB lists four extant occurrences of Coyote ceanothus, all of which are within 4 miles of each another (U.S. Fish and Wildlife Service 1995; U.S. Fish and Wildlife Service 1998; California Native Plant Society 2006). However, for the purposes of this Plan, the two occurrences in the vicinity of Anderson Dam (CNDDDB Occurrence numbers 6 and 8) are considered one occurrence. The other two occurrences are at Kirby Canyon and near Llagas Avenue north of Morgan Hill (U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2006). All three occurrences are on private land, except for a small part of the Anderson Dam occurrence, which partially falls within Anderson Lake County Park (California Natural Diversity Database Occurrence #8).

## Natural History

### Habitat Requirements

Coyote ceanothus is generally found growing on dry slopes in chaparral, grassland, and coastal scrub on serpentine soils, from approximately 400–1,500 feet (U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2006; California Native Plant Society 2006). Species commonly associated with Coyote ceanothus are California sagebrush (*Artemisia californica*), foothill pine (*Pinus sabiniana*), bigberry manzanita (*Arctostaphylos glauca*), toyon (*Heteromeles arbutifolia*), California coffeeberry (*Frangula [Rhamnus] californica*), and leather oak (*Quercus durata*) (U.S. Fish and Wildlife Service 1998). Some occurrences of Coyote ceanothus are almost pure stands of this species (U.S. Fish and Wildlife Service 2011).

**Table 1.** Habitat Associations for Coyote Ceanothus

Land Cover Type	Habitat Designation	Habitat Parameters	Percent Suitable	Rationale
Mixed serpentine chaparral	Primary habitat	Dry shallow slopes 400–1,500 feet	High	U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2006; California Native Plant Society 2006
Serpentine bunchgrass grassland	Primary habitat	400–1,500 feet	High	Same as above

## Population Ecology

Recent research and observation strongly suggest that periodic fire may be crucial for germination and regeneration of senescent stands of this plant (U.S. Fish and Wildlife Service 2011). The only known observations of seedlings in nature occurred after fires in Kirby Canyon (K. Freas 1996 in U.S. Fish and Wildlife Service 1998) and at Anderson Reservoir (J. Hillman 2006; U.S. Fish and Wildlife Service 2011). The latter population burned in 2003 and significant recruitment was observed in 2004. Many young shrubs of the same size and age class were also observed at that site in 2006. In surveys conducted in the 1980s, there were few young shrubs and no signs of reproduction present in the Anderson Dam populations (Schmidt 1996 in U.S. Fish and Wildlife Service 1998). At least one ceanothus expert feels that Coyote ceanothus may require some frequency of burning in order to maintain healthy populations that include young shrubs.

The lack of seedling recruitment seen in natural populations may also be due to seed or seedling mortality caused by factors such as seed predation, grazing and browsing, lack of sufficient precipitation to maintain young plants through dry summer following germination, or several of these together. Key seasonal periods for the species are listed in Table 2.

**Table 2.** Key Seasonal Periods for Coyote Ceanothus

	Jan	Feb	March	April	May	June	July	Aug	Sep	Oct	Nov	Dec
Germination	✓	✓								✓	✓	✓
Flowering	✓	✓	✓	✓	✓							
Fruiting		✓	✓	✓	✓	✓						
Seed Dispersal					✓	✓	✓	✓	✓	✓	✓	

## Population Status and Trends

**Global:** *Declining* (NatureServe 2006)

**State:** *Declining* (NatureServe 2006)

**Within Study Area:** *Declining* (California Native Plant Society 2006; NatureServe 2006)

The four documented occurrences include approximately 189,475 plants in total based on estimates from the Recovery Plan (U.S. Fish and Wildlife Service 1998) and a field survey conducted in 2009 by the SCVWD of the population near Anderson Dam (SCVWD, unpublished data). The largest population by far, approximately 188,475 individuals, is near Anderson Dam. The majority of the plants in the larger of the two subpopulations near the Dam emerged following a fire in 2003 (U.S. Fish and Wildlife Service 2011). The two occurrences located there may have been continuous prior to construction of the Dam (U.S. Fish and Wildlife Service 1998). The smallest population burned during the Kirby Canyon fire in 1992. Although only 5% of the individuals survived, around 2,000 seedlings were seen in the spring of 1993. Approximately 100 seedlings were individually caged to ward off grazers and seemed to be doing well when observed the following year (K. Freas pers. comm. 1996 in U.S. Fish and Wildlife Service 1998). Approximately 150 plants were observed during a survey of the Kirby Canyon population in the fall of 2010 (U.S. Fish and Wildlife Service 2011). Approximately 500 individuals, all of the same age class, were observed in the third population at Llagas Avenue north of Morgan Hill in 1997 (California Department of Fish and Game 1997 in U.S. Fish and Wildlife Service 1998). During surveys in the fall of 2010 around 600 to 650 plants were observed in this same location (U.S. Fish and Wildlife Service 2011).

## Threats

Documented threats to Coyote ceanothus include habitat loss and fragmentation, residential development, illegal trash dumping, recreation, landfill activities, lack of natural recruitment, altered fire regimes, grazing, and genetic isolation and limited insect-mediated gene flow (U.S. Fish and Wildlife Service 1998; 2011). The largest population near Anderson Dam is bisected by an existing gas utility line operated by The Pacific Gas and Electric Company (K. Devitorrio pers. comm.). Routine and emergency maintenance of this underground gas line may impact this key population. This population could also be threatened by Santa Clara Valley Water District work on the reservoir and dam maintenance, including the proposed seismic retrofit of the dam. Trail maintenance by Santa Clara County Parks could also pose a threat to this species.

## Data Characterization

Because Coyote ceanothus is a large and conspicuous shrub, it is thought that most of the occurrences of this species are known. However, it is possible that some individuals and populations have been overlooked because they are

mistaken for more common species of *Ceanothus*, including the closely related buckbrush (*C. cuneatus*). Further, some hybridization between Coyote ceanothus and buckbrush is suspected to occur and some hybrid populations may exist on Pallousou Ridge adjacent to Henry Coe State Park (T. Cochrane pers. comm.) and in other areas.

Recent research, in addition to anecdotal accounts, indicates that interspecific hybridization occurs between species of *Ceanothus* (Hardig et al., 2000; U.S. Fish and Wildlife Service 2011) and it is now widely accepted that hybrid speciation has occurred in the subgenus *Cerastes*, of which Coyote ceanothus is a species (Hardig et al. 2000). Ongoing genetic studies on this plant may provide additional information on the genetic status, genetic diversity, and population structure of Coyote ceanothus (U.S. Fish and Wildlife Service 2011). This research may provide useful information for the restoration and recovery of this species.

A good account of the habitat and occurrences of Coyote ceanothus can be found in the *Recovery Plan for Serpentine Soil Species of the San Francisco Bay Area* (U.S. Fish and Wildlife Service 1998) and in *Ceanothus ferrisiae (Coyote ceanothus) 5-Year Review: Summary and Evaluation* (U.S. Fish and Wildlife Service 2011). The documented habitat requirements of this species suggest that it should be more widespread than it is, indicating that our knowledge of the species population dynamics are incomplete. The species' habitat requirements may be highly specialized, or other factors are preventing the species' spread into otherwise suitable areas.

## Existing Conservation Actions in the Study Area

Waste Management, Inc. and The Nature Conservancy funded K. Freas's research (mentioned above) on Coyote ceanothus (U.S. Fish and Wildlife Service 1998). In the summer of 1992, the Kirby Canyon population burned. The following spring, 2,000 seedlings were observed and were fenced to protect them from grazing. Additional caging on some plants was added to protect against deer and rabbit grazing (K. Freas pers. comm. 1996 in U.S. Fish and Wildlife Service 1998). The Santa Clara Valley Water District was involved in mitigating for impacts on Coyote ceanothus resulting from the enlargement of the spillway to Anderson Dam (Santa Clara Valley Water District 1993 in U.S. Fish and Wildlife Service 1998). Two shrubs were successfully transplanted in 1997 (C. Roessler pers. comm. 1996 in U.S. Fish and Wildlife Service 1998), however they did not survive (R. Austin 2006). Waste Management, Inc. and Santa Clara Valley Water District have done some revegetation work with Coyote ceanothus that has not impacted the status of the species (K. Freas pers. comm. 1996 and D. Amshoff pers. comm. 1997 in U.S. Fish and Wildlife Service 1998). There are no on-going conservation efforts for Coyote ceanothus known to occur in the study area. A Santa Clara Valley Water District spillway modification project in 1992 planted approximately 175 seedlings; their current status is not known.

**Table 4.** Conservation Actions in the Study Area for Coyote Ceanothus

Action	Timing	Lead Agency	Location
Population ecology research	Implemented	Waste Management, Inc. and Nature Conservancy	Kirby Canyon population
Revegetation experimentation	Implemented	Waste Management, Inc. and Santa Clara Valley Water District	Anderson Dam population
Translocation	Implemented, Unsuccessful	Santa Clara Valley Water District	Anderson Dam population
Seedling outplanting	Implemented	Santa Clara Valley Water District	Need to find out from J. Hillman

## Modeled Habitat Distribution in Study Area

A habitat distribution model was not developed for this species because of the extremely limited range of the species and the uncertainty in its localized habitat requirements. A habitat model based on known habitat requirements that have been mapped at a regional scale (i.e., land cover types for this HCP/NCCP) would result in a model that greatly overestimates available habitat.

## Mount Hamilton Thistle (*Cirsium fontinale* var. *campylon*)

### Legal Status

**State:** California Native Plant Society List 1B.2<sup>1</sup>

**Federal:** None

**Critical Habitat:** N/A

**Recovery Planning:** *Recovery Plan for Serpentine Soil Species of the San Francisco Bay Area* (U.S. Fish and Wildlife Service 1998)

### Taxonomy

Mount Hamilton thistle was originally described by Helen Sharsmith, based on collections from Del Puerto Canyon in the Mount Hamilton Range of western Stanislaus County (Sharsmith 1939). Sharsmith (1939: 89–90) discussed the close morphological and ecological similarities between this species and the two varieties of *Cirsium fontinale*. These similarities later led to the recognition of Mount Hamilton thistle as a variety of *Cirsium fontinale* (Keil and Turner 1992: 313). Mt. Hamilton thistle is within the aster family (Asteraceae).

### Description

Descriptions of the species' physical characteristics can be found in Sharsmith (1939: 85–86, Figure 1), Munz (1959: 1,276), Abrams and Ferris (1960: 538, Fig. 5934), and Keil and Turner (1993: 236). Mt. Hamilton thistle is a large herbaceous perennial thistle up to 2 to 6.5 feet tall with a single stem. The plant has woolly, spine-tipped leaves that are up to approximately 2 feet long at the base. The large flower heads have recurved bracts and often droop substantially.

### Distribution

#### General

Mount Hamilton thistle is endemic to the San Francisco Bay Area and occurs in Santa Clara, Stanislaus, and Alameda Counties. There are two clusters of populations, one in the Mount Hamilton Ranges, the other in the Santa Cruz Mountains (Figure 1). There are a total of 48 occurrences of Mount Hamilton thistle are known within its range, 40 of which occur within the study area.

<sup>1</sup> 1B means rare, threatened, or endangered in California and elsewhere; .2 means fairly endangered in California.

Thirty-one of the occurrences within the study area are listed with the California Natural Diversity Database (CNDDDB) (2010). The remaining nine occurrences are not listed with the CNDDDB and are detailed below.

## Occurrences within the Study Area

### Extant

Forty occurrences of Mount Hamilton thistle are known to occur in the study area, all of which have been documented within the last 20 years. Occurrences in the study area are generally found in two areas (Figure 2): In the Santa Teresa Hills and East of Highway 101 in the low hills and canyons along Coyote Ridge and the Silver Creek Hills. Thirty-one occurrences were reported in the CNDDDB (2010). In addition,, two occurrences were reported on the United Technologies Corporation property (T. Marker pers. comm.), four occurrences were found on Santa Clara County Park lands, two occurrences were found on Rancho San Vicente, and one occurrence was recently reported by SCVWD on or near their facilities. Occurrences in northeastern Santa Clara County are outside the study area.

## Natural History

### Habitat Requirements

Mount Hamilton thistle occurs on serpentine soils in seeps and springs and along intermittent and perennial streams. The surrounding habitat is often serpentine bunchgrass grassland, although sometimes the occurrences are within foothill pine woodland or coast live oak forest and woodland (Table 1). The occurrences range in elevation from 320 feet to 2,900 feet.

Species primarily associated with Mount Hamilton thistle include seep monkeyflower (*Mimulus guttatus*) and hedge-nettle (*Stachys pycnantha*), as well as sedge species (*Carex* spp.), iris-leaved rush (*Juncus xiphioides*), and hoary coffeeberry (*Frangula* [*Rhamnus*] *californica* ssp. *tomentella*). Additional associates include Brewer's willow (*Salix breweri*), California poppy (*Eschscholzia californica*), columbine (*Aquilegia eximia*), common yarrow (*Achillea millefolium*), long-rayed triteleia (*Triteleia peduncularis*), and beardless wild rye (*Leymus* [*Elymus*] *triticoides*) (Pilz 1967; U.S. Fish and Wildlife Service 1998).

**Table 1.** Habitat Associations for Mount Hamilton Thistle

Land Cover Type	Habitat Designation	Habitat Parameters	Rationale
Serpentine bunchgrass grassland	Primary habitat (in suitable aquatic habitat)	In seeps and springs and along intermittent and perennial streams, 320–2,900 feet elevation.	California Natural Diversity Database 2010
Serpentine seep	Primary habitat	In seeps and springs and along intermittent and perennial streams, 320–2,900 feet elevation.	
Foothill pine—oak woodland <sup>1</sup>	Primary habitat (in suitable aquatic habitat)	In seeps and springs and along intermittent and perennial streams, 320–2,900 feet elevation.	California Natural Diversity Database 2010
Coast live oak forest and woodland <sup>1</sup>	Primary habitat (in suitable aquatic habitat)	In seeps and springs and along intermittent and perennial streams, 320–2,900 feet elevation.	California Natural Diversity Database 2010

<sup>1</sup> The species occurs in serpentine seeps within this woodland type, but does not occur in terrestrial habitat of this woodland type.

## Population Ecology

Mount Hamilton thistle generally occurs in small stands of a few plants to several thousand plants, although some larger stands are known (U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2010). One location in Santa Clara County in 1992 supported over 18,000 plants (California Natural Diversity Database 2010). The reproductive biology and demography of this species are unknown.

The highly restricted habitat requirements of this species likely greatly limits the species' distribution and abundance. Research indicates that native insects play an important role in the population biology of another endangered *Cirsium* species. Experimental treatments to exclude or reduce moth larvae, weevil larvae, aphids, spittle bugs, and mealybugs from juvenile rosettes of the endangered Pitcher's thistle (*Cirsium pitcheri*) in rare dune habitat of Michigan resulted in substantial increases in plant survival, growth, and seed production where these insects were common (Bevill et al. 1999). These results also suggest that native insects can influence the spatial distribution of native plants. The susceptibility of Mount Hamilton thistle to native or exotic insect herbivory is unknown.

**Table 2.** Key Seasonal Periods for Mount Hamilton Thistle

	Jan	Feb	March	April	May	June	July	Aug	Sep	Oct	Nov	Dec
Germination	✓	✓	✓	✓						✓	✓	✓
Flowering		(✓)	(✓)	✓	✓	✓	✓	✓	✓	(✓)		
Fruiting			✓	✓	✓	✓	✓	✓	✓	✓	✓	
Seed Dispersal			✓	✓	✓	✓	✓	✓	✓	✓	✓	

Notes: (✓) Indicates flowering period during certain years.

## Population Status and Trends

**Global:** Unknown, but may be stable

**State:** Same

**Within Study Area:** Same

All occurrences of Mount Hamilton thistle are presumed to be extant (California Natural Diversity Database 2010). Populations of this species are conspicuous and have not shown any obvious signs of population decline or range contraction (Weiss pers. comm.).

## Threats

Reported threats to populations of Mount Hamilton thistle in the study area include alteration of hydrologic regimes, urbanization and cattle grazing (U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2010). Urbanization potential is very limited within the range of the species due to its occurrence in deep canyons outside areas designated for urban development. The effects of livestock grazing on this species are unknown. The spiny leaves likely limit grazing of plant tissue but Mount Hamilton thistle may be susceptible to trampling by cattle due to their occurrence in and near livestock water sources. Road construction or future landfills may pose a threat. Expansion of the Kirby Canyon Landfill is expected to remove at least one population or portion of a population of Mount Hamilton thistle.

The introduction of aggressive insect herbivores is a common technique to control invasive weedy thistles. Native thistles have been shown to be negatively affected by these biological control agents. For example, Louda and O'Brien (2002) demonstrated that the Eurasian weevil (*Larinus planus*), which is distributed in North America for the control of Canada thistle (*Cirsium arvense*), had spread to native populations of Tracy's thistle (*Cirsium undulatum* var. *tracyi*) in Colorado. Canada thistle is found throughout most of California, including Santa Clara County (Bossard et al. 2000).

A European flower-head weevil *Rhinocyllus conicus* introduced to control exotic thistles was found to destroy flower heads of many native thistles, including *C.*

*fontinale* (Turner et al. 1987; Turner and Herr 1996). Another study found *R. conicus* feeding on other native thistles in southern California (Goeden and Ricker 1986). A study in 2005 found *R. conicus* in the seed heads of *C. fontinale* var. *campylon* (J. Hillman 2006) however work done by Herr (2000) found no evidence of biologically significant impact of the weevil on native Californian *Cirsiums*, including *C. fontinale* var. *campylon*. This flower-head weevil is approved by the U.S. Department of Agriculture for control of exotic thistles common in the study area including bull thistle (*Cirsium vulgare*), milk thistle (*Silybum marianum*), and Italian thistle (*Carduus pycnocephalus*). However, studies have not shown this biocontrol agent to be particularly effective at controlling these invasive plants (Bossard et al. 2000). Its effects on *C. fontinale* var. *campylon* are unknown but the research cited above suggests that biological control of invasive weeds may be a threat to this rare native taxa.

## Data Characterization

Available information is likely to adequately characterize the species' habitat requirements. However, very little data is available on the species' population biology, and no data is available on the management needs of the species. More information is also needed on threats to this species in the study area.

## Existing Conservation Actions in the Study Area

No conservation actions in the study area have directly targeted Mount Hamilton thistle. Protection of some habitat along Coyote Ridge to provide mitigation for impacts to Bay checkerspot butterfly and serpentine grassland, along with improved livestock management in this area have indirectly benefited Mount Hamilton thistle.

## Modeled Habitat Distribution in Study Area

### Model Description

#### Model Assumptions

Primary habitat within the study area is defined as serpentine seeps or serpentine soils or grasslands within 25 feet of riverine habitat. This species is only found within the Guadalupe and Coyote watersheds.

## Rationale

Mount Hamilton thistle occurs on areas with serpentine characteristics. This can be any combination of serpentine soils, seeps or springs, typically along streams. The surrounding habitat is often serpentine bunchgrass grassland. The occurrences range in elevation from 320 feet to 2,900 feet.

## Model Results

Figure 2 shows the modeled potential habitat for the Mt. Hamilton thistle within the study area. The potential habitat is confined to known serpentine areas, mostly along Coyote Ridge and in the Santa Teresa Hills. Most of the known occurrences fall within the modeled habitat. Some occurrences may fall outside modeled habitat due to the mapping limitations of springs of serpentine origin.

## Santa Clara Valley Dudleya (*Dudleya abramsii* ssp. *setchellii*)

### Legal Status

**State:** California Native Plant Society 1B.1<sup>1</sup>

**Federal:** Endangered (U.S. Fish and Wildlife Service 1995)

**Critical Habitat:** None

**Recovery Planning:** *Recovery Plan for Serpentine Species of the San Francisco Bay Area* (U.S. Fish and Wildlife Service 1998)

© Janell Hillman

### Taxonomy

Santa Clara Valley dudleya was first collected by the famous botanist Willis Jepson on Tulare Hill at the turn of the last century (Jepson 1901). The species was originally described as *Cotyledon laxa* var. *setchelli*. In 1903, this taxa was elevated to full species status and transferred to the new genus *Dudleya* (Britton and Rose 1903). The taxa was subsequently reduced to the subspecies level as *Dudleya cymosa* ssp. *setchelli* (Moran 1959; Nakai 1987). It was elevated from subspecies to species level by Bartel in his treatment of the genus, resurrecting the original species name from 1903 (Hickman 1993). Most recently, it was again reduced to the subspecies level as *Dudleya abramsii* ssp. *setchellii* (Baldwin et al. 2012). Santa Clara Valley dudleya is a member of the stonecrop family (Crassulaceae).

### Description

Descriptions of the species' physical characteristics can be found in Hickman (1993) and in the *Recovery Plan for Serpentine Species of the San Francisco Bay Area* (U.S. Fish and Wildlife Service 1998). Santa Clara Valley dudleya is a perennial with succulent leaves one to three inches long and 0.3 to 0.6 inches wide. The species produces two to three flowering stalks up to 8 inches tall with pale yellow flowers in a terminal inflorescence.

<sup>1</sup> 1B means rare, threatened, or endangered in California and elsewhere; .1 means seriously endangered in California

## Distribution

### General

Santa Clara Valley dudleya is only found in Santa Clara County in the vicinity of Coyote Valley, from San José south about 20 miles to San Martin, at elevations of 300–900 feet (Figure 1).

### Occurrences within the Study Area

Two hundred and seven occurrences have been documented within the study area between 1989 and 2012, and all of these are presumed to be extant (Figure 2) (H.T. Harvey and Associates 2000; California Natural Diversity Database 2010, 2012; T. Marker pers. comm.). The estimated number of individuals known for the species varies greatly due in part to the variation in the methodology of counting the rosettes which are formed as individual plants spread vegetatively (Jones & Stokes 1998). Forty-nine occurrences were reported in the California Natural Diversity Database (20122012), 109 occurrences from the United Technologies Corporation (T. Marker pers. comm.), 48 occurrences from Santa Clara County Parks, and one from the Santa Clara Valley Water District.

An unconfirmed occurrence in the study area documented in 2006 is not included as a known occurrence (RCL Ecology Biological Consulting 2006). The occurrence was found near Highway 152 approximately 2 miles east of Casa de Fruta. There was no record of the occurrence in CNDDB and the identity of the plant has not been confirmed since its documentation. Still, this unconfirmed occurrence is significant as it was found further south than any other known occurrence.

## Natural History

### Habitat Requirements

Santa Clara Valley dudleya is restricted to rocky outcrops in serpentine grassland and oak woodland at elevations between 300 and 900 feet. McCarten (1993) suggests that suitable rock outcrops must have deep enough crevices for this species' roots, which are at least 6 inches long. Not all serpentine rock outcrops, therefore, may be suitable for Santa Clara Valley dudleya. Table 1 lists expected land cover associations for this species.

The rock outcrops where this species is found are otherwise largely unvegetated. However, adjacent serpentine grasslands typically are dominated by a mixture of native grasses, such as purple needlegrass (*Stipa* [*Nasella*] *pulchra*), and non-native grasses, such as wild oats (*Avena* spp.) and soft chess (*Bromus hordeaceus*). Native forbs are also common associates of this species, including lomatium (*Lomatium* spp.), soap plant (*Chlorogalum pomeridianum*), dwarf

plantain (*Plantago erecta*), California poppy (*Eschscholzia californica*), and naked buckwheat (*Eriogonum nudum*) (U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2010). Santa Clara Valley dudleya may also occur on serpentine rock outcrops in oak woodland or savanna, where coast live oak (*Quercus agrifolia*) and valley oak (*Quercus lobata*) have been reported as associates (California Natural Diversity Database 2010).

**Table 1.** Habitat Associations for Santa Clara Valley Dudleya

Land Cover Type	Suitability	Rationale
Serpentine bunchgrass grassland	Moderate	Rock outcrops present in serpentine grassland may be below the minimum mapping unit size but still provide habitat.
Serpentine rock outcrop/barrens	High	Primary habitat for species (California Natural Diversity Database 2010; U.S. Fish and Wildlife Service 1998)
Valley oak woodland	Low	Reported from serpentine rock outcrops within Valley Oak savannah (California Natural Diversity Database 2010)
Coast live oak forest and woodland	Low	May occur on serpentine rock outcrops in cismontane woodland (California Native Plant Society 2006). Coast live oak is reported as an associate (California Natural Diversity Database 2010).
Mixed oak woodland and forest	Low	May occur on serpentine rock outcrops in cismontane woodland (California Native Plant Society 2006). Coast live oak is reported as an associate (California Natural Diversity Database 2010).

## Population Ecology

Santa Clara Valley dudleya produces wind-dispersed seeds (McCarten 1993), and also reproduces vegetatively by forming rosettes that either remain attached to the parent plant or separate from it. (Plants that remain attached to parents make counting unique individuals difficult.) Individual plants live for up to 10 years. Seedling germination is high in wet years, but seedling survival is low, often less than 5% (McCarten 1993; U.S. Fish and Wildlife Service 1998). The highest seedling survival rates were on east- and north-facing slopes, suggesting that dessication may be a major source of seedling mortality (McCarten 1993; Jones & Stokes 1998). Suitable microhabitats on rock outcrops (crevices with enough soil to retain moisture) may greatly limit the population size of this species. Table 2 shows key seasonal periods for Santa Clara Valley dudleya.

**Table 2.** Key Seasonal Periods for Santa Clara Valley Dudleya

	Jan	Feb	Mar	April	May	June	July	Aug	Sep	Oct	Nov	Dec
Germination (unknown)										✓	✓	✓
Flowering				✓	✓	✓	✓					
Fruiting (unknown)						✓	✓	✓				
Seed Dispersal (unknown)	(✓)	(✓)	(✓)	(✓)	(✓)	✓	✓	✓	(✓)	(✓)	(✓)	(✓)

Notes: (✓) Indicates seed dispersals period in some years

## Population Status and Trends

**Global:** *Stable?*

**State:** *Stable?*

**Within Study Area:** *Stable?*

Insufficient data are available to characterize long-term demographic trends within populations (California Natural Diversity Database 2010). However, it has been suggested that populations of Santa Clara Valley dudleya may be stable because of the stability of their microhabitats in crevices on serpentine rock outcrops (S. Weiss pers. comm.). Population monitoring is needed to confirm this hypothesis.

## Threats

The primary threats to Santa Clara Valley dudleya are overgrazing, development, and competition from non-native species (U.S. Fish and Wildlife Service 1998; Weiss 1999; California Native Plant Society 2006; California Natural Diversity Database 2010). Overcollecting is also a significant threat to Santa Clara Valley dudleya because of its attractiveness to collectors, accessible population sites, and slow growth rate (U.S. Fish and Wildlife Service 1995). Other threats may include feral pigs, off-road vehicle use, and foot traffic (California Native Plant Society 2006; California Natural Diversity Database 2010).

## Data Characterization

The general habitat requirements of Santa Clara Valley dudleya and the species distribution within its narrow range are relatively well understood. For example, a County-wide survey for this species was conducted in 2000 (H.T. Harvey and Associates 2000), and local botanists with the California Native Plant Society have been devoting significant attention to identifying and protecting local populations (D. Mayhall pers. comm.). The species' microhabitat requirements are not well understood, nor are the species' demography or pollination biology. The management needs of the species also need investigation.

## Existing Conservation Actions in the Study Area

The recovery plan for Santa Clara Valley dudleya calls for protection and management of extant populations, as well as educational outreach in the San José area and collection and banking of seed (U.S. Fish and Wildlife Service 1998). Recommended research topics to inform conservation efforts include research on the effects of vegetation management on the species, demographic and dispersal studies, and research on the efficacy of seed germination and propagation techniques.

Protection of mitigation lands on Coyote Ridge and other sites such as the Valley Christian High School site (Jones & Stokes 1998) have preserved some habitat for Santa Clara Valley dudleya.

## Modeled Habitat Distribution in Study Area

A habitat distribution model for Santa Clara Valley dudleya could not be developed because of the highly specialized and localized habitat requirements of the species. It is restricted to serpentine outcrops within annual grassland and oak woodland. However, only rock outcrops with sufficient crevice depth and soil depth within these crevices are likely to support the species. Serpentine rock outcrops were mapped in the study area, but only the largest outcrops were visible on the aerial photographs. This land cover type is therefore likely underrepresented on the land cover map. This species has received significant attention by the local botanical community in the last 5–10 years, particularly leading up to and since listing the species as endangered in 1995. As a result, the species' distribution is assumed to be well understood, and many large populations are known and mapped. New populations are still being discovered and it is likely that there are many unknown populations, the discovery of which will expand our estimate of total population size. However, because this species is relatively easily located and locally somewhat widespread, there is less need for a habitat distribution model to predict unknown occurrences.

## Fragrant Fritillary (*Fritillaria liliacea* Lindl.)

### Legal Status

**State:** California Native Plant Society List 1B.2<sup>1</sup>

**Federal:** None

**Critical Habitat:** None

**Recovery Planning:** None

© Gerald and Buff Corsi,  
California Academy of Sciences

### Taxonomy

Fragrant fritillary (*Fritillaria liliacea*) is the accepted nomenclature. See *Madroño* 7:133–159 (1944) for revised nomenclature (Corelli and Chandik 1995). Fragrant fritillary is in the lily family (Liliaceae).

### Description

Descriptions of the species' physical characteristics can be found in Baranova (1981); Hickman (1993), and in Corelli and Chandik (1995). Fragrant fritillary, a bulbiferous monocot, is a perennial herb possessing a white flower that grows up to 35 cm in height (Calflora 2006; Hickman 1993). The lower leaves are opposite, mostly basal, and somewhat succulent while the upper leaves are alternate and smaller (Corelli and Chandik 1995).

### Distribution

#### General

Fragrant fritillary is known from 59 occurrences (California Natural Diversity Data Base 2006) throughout its range. It is endemic to western central California, ranging from Sonoma and Solano Counties south to Monterey County (Figure 1, California Natural Diversity Database 2006).

<sup>1</sup> 1B means rare, threatened, or endangered in California and elsewhere; .2 means fairly endangered in California.

## Occurrences within the Study Area

### Historical

A specimen of fragrant fritillary was collected prior to 1941 in Alum Rock Park in the vicinity of the Alum Rock Spring (California Natural Diversity Database occurrence #33). A survey of this area conducted in 1994 found the habitat extant, but failed to locate any occurrences of the species, so the current status of this population is unknown (California Natural Diversity Database 2006).

### Extant

There are eight reported occurrences of fragrant fritillary in the study area (Figure 2, California Natural Diversity Database 2010). Four occurrences are located on private land. Three of these (#25–27) are located east of Santa Clara Valley, southeast of Metcalf Canyon and less than a mile south or southeast from Metcalf VABM (Vertical Angle Benchmark, U.S. Geological Survey Morgan Hill quad) while one lies southwest of Metcalf VABM (#54). Two occurrences (#30 and 31) are located on County-owned parkland. Occurrence #30 was recorded in Calero County Park, near the south arm of Calero Reservoir while occurrence #31 was documented in Almaden Quicksilver County Park. Occurrence #32 was noted on private land about 1.5 miles south from the town of Evergreen, east of San José.

## Natural History

### Habitat Requirements

Fragrant fritillary occurs in grasslands, woodland, and coastal scrub up to 1,345 feet (California Natural Diversity Database 2006; California Native Plant Society 2006) and in vernal pool areas (California Natural Diversity Database 2006; Sawyer and Keeler-Wolf 1995). The species typically occurs on serpentine soils, although occurrences on heavy clay soils and other soil types have also been reported (California Natural Diversity Database 2006). Serpentine grasslands in the study area are the most likely habitat for this species (Table 1). Some species commonly associated with fragrant fritillary are purple needlegrass (*Stipa* [*Nassella*] *pulchra*), blue dicks (*Dichelostemma capitatum*), soap plant (*Chlorogalum pomeridianum*), sun cups (*Taraxia* [*Camissonia*] *ovata*), purple clarkia (*Clarkia purpurea*), and coyote brush (*Baccharis pilularis*) (Corellia and Chandik 1995; California Natural Diversity Database 2006).

**Table 1.** Habitat Associations for Fragrant Fritillary

Land Cover Type	Habitat Designation	Habitat Parameters	Percent Suitable	Rationale
Serpentine Bunchgrass Grassland	Primary	Often on serpentine grasslands between 10 and 1,345 feet in elevation.	Unknown	California Natural Diversity Database 2006
California Annual Grassland; Northern Coastal Scrub/Diablan sage scrub; Valley Oak Woodland; Mixed Oak Woodland; Blue Oak Woodland; Coast live Oak Woodland; Seasonal Wetlands	Secondary	Various soil types though most often clay, including serpentine, between 10 and 1,345 feet elevation	Unknown	California Natural Diversity Database 2006

## Population Ecology

The population ecology of fragrant fritillary is largely unknown. The blooming period of this species is very early in the season (Table 2).

**Table 2.** Key Seasonal Periods for Fragrant Fritillary

	Jan	Feb	March	April	May	June	July	Aug	Sep	Oct	Nov	Dec
Germination										✓	✓	✓
Flowering		✓	✓	✓								
Fruiting			✓	✓	✓							
Seed Dispersal						✓	✓	✓				

## Population Status and Trends

**Global:** Declining (NatureServe 2006)

**State:** Declining (NatureServe 2006)

**Within Study Area:** Unknown

Nine documented occurrences of fragrant fritillary are believed to be extirpated in the state as a whole (California Natural Diversity Database 2006). Two populations are reported as stable and two as decreasing, but population trends for the other occurrences are unknown (California Natural Diversity Database 2006). For 21 occurrences, the habitat in which fragrant fritillary occurs is rated good to excellent, suggesting that the populations are likely to be stable. Habitat quality is rated as fair for 10 occurrences and unknown for 18 occurrences. The population sizes of fragrant fritillary in the study area are unknown. Population

sizes reported for the species in Solano County on the Jepson Prairie Preserve range from 20 to 100 plants (LSA 2005).

## Threats

Some common threats to fragrant fritillary are loss of habitat to urban development and agriculture (Corelli and Chandik 1995), competition from invasive exotic species, and grazing (California Natural Diversity Database 2006). In Santa Clara County, additional threats are from recreation and feral pigs (California Natural Diversity Database 2006).

## Data Characterization

Very little information is available for fragrant fritillary. The literature on the species pertains primarily to its taxonomy. The main sources of general information on this species are the *Jepson Manual* (Hickman 1993) and the California Native Plant Society (California Native Plant Society 2006). Specific observations on habitat and plant associates, threats, and other factors are present in the California Natural Diversity Data Base (California Natural Diversity Database 2006).

## Existing Conservation Actions in the Study Area

No conservation actions have been implemented or are planned in the study area that target fragrant fritillary. A recovery plan for the serpentine soil species of the San Francisco Bay Area was compiled in 1998 in which can be found specific management efforts being carried out in the Bay Area. Fragrant fritillary is included as a frequent associate of some of these species (U.S. Fish and Wildlife Service 1998).

## Modeled Habitat Distribution in Study Area

### Model Description

#### Model Assumptions

1. Primary habitat is defined as serpentine bunchgrass grassland between 0 and 1,500 feet elevation on slopes with all degrees of steepness.
2. Secondary habitat is defined as annual grassland, northern coastal scrub/Diablan sage scrub, and all oak woodland land cover types on slopes with all degrees of steepness between 0 and 1,500 feet elevation.

Both types of suitable habitat apply in the following ecoregion subsections: Fremont-Livermore Hills and Valleys, Leeward Hills, Santa Cruz Mountains, Western Diablo Range, and Diablo Range.

## Rationale

Fragrant fritillary occurs primarily on serpentine soils in grasslands (California Natural Diversity Database 2006). The species also occurs on non-serpentine soils in grasslands, oak woodland, and coastal scrub up to 1,345 feet (California Natural Diversity Database 2006; California Native Plant Society 2006).

## Model Results

Figure 2 shows the modeled potential habitat for fragrant fritillary within the study area. Suitable habitat is found in the foothills on the east and west sides of the valley floor. Most of the modeled habitat is secondary habitat for this species. All eight known occurrences in the study area are located on modeled habitat.

## Loma Prieta Hoita (*Hoita strobilina*)

### Legal Status

**State:** California Native Plant Society  
List 1B.1<sup>1</sup>

**Federal:** None

**Critical Habitat:** N/A

**Recovery Planning:** N/A

### Taxonomy

Loma Prieta hoita was originally described in 1838 as *Psoralea strobilina*, based on collections made in California during the expedition led by Captain Frederick Beechey to the Pacific and Bering Strait from 1825 to 1828 (Hooker and Arnott 1838: 332). Rydberg (1919: 11) later transferred the species to *Hoita*. Rydberg's recognition of the genus *Hoita* was not generally accepted until recently (Grimes 1990). Loma Prieta hoita is in the legume family (Fabaceae).

### Description

Descriptions of the species' physical characteristics can be found in Rydberg (1919: 11), Abrams (1944: 554, Figure 2753), Munz (1959: 852), and Grimes (1993: 610). Loma Prieta hoita is herbaceous plant up to three feet tall with three leaflets per leaf and dense terminal clusters of purple flowers. This species is distinguished from other species of *Hoita* by the length and structure of the calyx lobes and flower petals.

### Distribution

#### General

Loma Prieta hoita is endemic to California, where it occurs primarily in the Santa Cruz Mountains of Santa Clara and Santa Cruz Counties (Figure 1). The species also occurs in the Diablo Range in Santa Clara, Alameda, and Contra Costa Counties. There are 26 known occurrences of Loma Prieta hoita (California Natural Diversity Database 2006).

<sup>1</sup> 1B means rare, threatened, or endangered in California and elsewhere; .1 means seriously endangered in California.

## Occurrences within the Study Area

### Historical

Two historic occurrences (California Natural Diversity Database Occurrences #2 and 3) were recorded from near Gilroy (California Natural Diversity Database 2006).

### Extant

Fourteen occurrences of Loma Prieta hoita have been reported from the study area (California Natural Diversity Database 2010). Three occurrences are located in Almaden Quicksilver County Park (California Natural Diversity Database Occurrence #5, #23, and #24). An occurrence consisting of three colonies was reported from Santa Teresa County Park (California Natural Diversity Database Occurrence #6). Two occurrences were reported from the hills east of Coyote Creek, one on private land and one on land of unknown ownership (California Natural Diversity Database Occurrence #10 and #11 respectively). Three occurrences were reported from Rancho Cañada del Oro Open Space Preserve (California Natural Diversity Database Occurrence #13, #25, and #26). One occurrence was reported in the vicinity of Chesbro Reservoir (California Natural Diversity Database Occurrence #16). One occurrence was reported from along Javelina Loop Trail in Calero County Park (California Natural Diversity Database Occurrence #22). Three new occurrences were added from field data collected by Tom Cochrane and John Folkowski at Santa Clara County Parks (2010): One occurrence within Rancho San Vicente and two just east of Almaden Quicksilver Park boundaries.

Two additional occurrences are outside the study area east of Highway 17, including one reported in 2004 at Sierra Azul Open Space Preserve (California Natural Diversity Database Occurrence #12). In addition, collections made on Loma Prieta Peak and at the head of Uvas Creek on lands of unknown ownership (California Natural Diversity Database Occurrence #4) may be within the study area. Figure 2 shows the locations of these occurrences.

## Natural History

### Habitat Requirements

Loma Prieta hoita generally occurs as an understory element of coast live oak forest and woodland, generally in riparian woodland or on shaded slopes, between 100 and 2,000 feet elevation. Coast live oak (*Quercus agrifolia*) is the dominant canopy tree, associated with California bay (*Umbellularia californica*), valley oak (*Quercus lobata*), or white alder (*Alnus rhombifolia*). The understory is often shrubby, composed of poison oak (*Toxicodendron diversilobum*), toyon (*Heteromeles arbutifolia*), big-berry manzanita (*Arctostaphylos glauca*), bush monkeyflower (*Mimulus aurantiacus*), and coffeeberry (*Frangula [Rhamnus]*)

spp.). Although the California Natural Diversity Database reports that the species sometimes occurs in chaparral or on serpentine (California Natural Diversity Database 2006), other sources note that this species primarily occurs on and is a strong indicator species for serpentine soils (Safford et al. 2005, California Native Plant Society 2012). Within the study area it seems to occur primarily on serpentine and secondarily on non-serpentine (J. Hillman pers. comm.). It also often occurs in the riparian zone. Generalized habitat requirements are shown in Table 1.

**Table 1.** Habitat Associations for Loma Prieta Hoita

Land Cover Type	Habitat Designation	Habitat Parameters	Percent Suitable	Rationale
Coast Live Oak Forest and Woodland; Mixed Oak Woodland	Primary	Primarily on serpentine soils on shaded slopes or along streams, between 100 and 2,000 feet elevation	Unknown	California Natural Diversity Database 2006; J. Hillman pers. comm.
Northern Mixed Chaparral/Chamise Chaparral	Secondary	All soil types, including serpentine between 100 and 2,000 feet elevation	Unknown, but possibly low	California Natural Diversity Database 2006

## Population Ecology

Populations generally consist of one to several stands composed of about a hundred plants, sometimes with up to a thousand plants in a stand (California Natural Diversity Database 2006). Key seasonal periods for the species are shown in Table 2.

**Table 2.** Key Seasonal Periods for Loma Prieta Hoita

	Jan	Feb	March	April	May	June	July	Aug	Sep	Oct	Nov	Dec
Germination	✓	✓	✓							✓	✓	✓
Flowering					(✓)	✓	✓	✓	✓	(✓)		
Fruiting							✓	✓	✓	✓	✓	
Seed Dispersal	✓						✓	✓	✓	✓	✓	✓

Notes: Months in parentheses are uncommon periods.

## Population Status and Trends

**Global:** *Unknown* (California Natural Diversity Database 2006)

**State:** *Unknown* (California Natural Diversity Database 2006)

**Within Study Area:** *Unknown* (California Natural Diversity Database 2006)

All but one occurrence of Loma Prieta hoita are presumed to be extant (California Natural Diversity Database 2006). One of the occurrences near Gilroy (California Natural Diversity Database occurrence #2) has possibly been extirpated.

## Threats

Few population threats are known for Loma Prieta hoita. Populations at roadsides or in power line rights-of-way are subject to vegetation clearing. At least one population is reported to be subject to cattle grazing and trampling and feral pig rooting. Wild pigs commonly root under oak canopies in the study area, severely disturbing the soil and uprooting most herbaceous plants. At least one population may be threatened by development.

## Data Characterization

Only 8 occurrences provide sufficient information to characterize the species' general habitat requirements. Very little data is available on the species' population biology, and no data is available on the management needs of the species. More information is also needed on threats to this species in the study area.

## Existing Conservation Actions in the Study Area

There are no known conservation actions in the study area focused on Loma Prieta hoita.

## Modeled Species Distribution in Study Area

### Model Description

#### Model Assumptions

1. Primary habitat is defined as mixed oak woodland and coast live oak forest and woodland between 100 and 2,000 feet in elevation on slopes with all degrees of steepness and in all soil types but primarily on serpentine soils.
2. Secondary habitat is defined as northern mixed chaparral/chamise chaparral and mixed serpentine chaparral between 0 and 2,000 feet in elevation on slopes with all degrees of steepness. Northern mixed chaparral applies in all soil types.

Potential ecoregion subsections include the Fremont-Livermore Hills and Valleys, Leeward Hills, Santa Cruz Mountains, Western Diablo Range, and the Diablo Range (i.e., all ecoregions except the Santa Clara Valley).

## Rationale

Loma Prieta hoita occurs as an understory element of oak woodland between 100 and 2,000 feet elevation, on shaded slopes or in riparian areas. The species associated with Loma Prieta hoita correspond with the coast live oak woodland and mixed oak woodland land cover types. Secondary habitat appears to be mixed northern chaparral and mixed serpentine chaparral.

## Model Results

Figure 2 shows the modeled potential habitat for Loma Prieta hoita within the study area. The potential habitat is spread throughout the study area, with the exception of the valley floor. The known occurrences of this species within the study area fall within the modeled habitat.

## Smooth Lessingia (*Lessingia micradenia* var. *glabrata*)

### Legal Status

**State:** California Native Plant Society  
List 1B.2<sup>1</sup>

**Federal:** None

**Critical Habitat:** N/A

**Recovery Planning:** U.S. Fish and Wildlife  
Service (1998)

© David Tharp

### Taxonomy

Smooth lessingia was originally described by D.D. Keck, based on a collection from the Santa Cruz Mountains between Los Gatos and Almaden, in Santa Clara County (Keck 1958: 105). It was originally described as *Lessingia ramulosa* var. *glabrata*. Keck (1958: 105) characterized var. *glabrata* as “exactly like *L. ramulosa* var. *micradenia*” except that var. *glabrata* lacked glandular hairs. Ferris (1958: 101) subsequently raised var. *micradenia* to species rank and transferred var. *glabrata* to *L. micradenia*, recombining the name as *Lessingia micradenia* var. *glabrata*. Smooth lessingia is in the sunflower family (Asteraceae).

### Description

Descriptions of the species’ physical characteristics can be found in Keck (1958: 105), Munz (1959: 1223), Abrams and Ferris (1960: 379), and Lane (1993: 306). Smooth lessingia is an annual herb that grows up to 60 cm tall. It has deciduous basal leaves less than 6 centimeters (cm) long, and linear leaves along the stem up to only 2 cm long. Smooth lessingia is distinguished from the related Tamalpais lessingia (*Lessingia micradenia* var. *micradenia*) by its three to five flowers per flower head.

<sup>1</sup> 1B means rare, threatened, or endangered in California and elsewhere; .2 means fairly endangered in California.

## Distribution

### General

Smooth lessingia is endemic to Santa Clara County on the eastern slopes of the Santa Cruz Mountains and the hills adjacent to the Santa Clara Valley (Figure 1). There are 39 known occurrences of smooth lessingia (California Natural Diversity Database 2008), all within the study area.

## Occurrences within the Study Area

### Historical

Four historical occurrences of smooth lessingia are known from the study area (California Natural Diversity Database 2006). These include occurrences reported from 1.5 miles southwest of San Martin in 1926 (California Natural Diversity Database Occurrence #1), from the eastern slope of Loma Prieta in 1893 (California Natural Diversity Database Occurrence #2), from north of Morgan Hill near Pigeon Point in 1937 (California Natural Diversity Database Occurrence #5), and from near Almaden in 1941 (California Natural Diversity Database Occurrence #9).

### Extant

There are thirty-nine extant occurrences of smooth lessingia within the study area, twenty-six of which are known from the California Natural Diversity Database (2008). The remaining occurrences were reported from the Santa Clara Valley Water District or Santa Clara County Parks and Recreation. Most of the smooth lessingia occurrences are located west of Highway 101 with the exception of several occurrences that occur directly adjacent to Highway 101 to the east. Occurrences occur primarily on private land although there are several occurrences in Santa Teresa County Park and one occurrence each in Calero and Mt. Madonna County Parks.

## Natural History

### Habitat Requirements

Smooth lessingia occurs on serpentine outcrops and in rocky soils in serpentine bunchgrass grassland. It appears to prefer areas with low vegetation cover, sometimes occurring on roadcuts or at roadsides. The occurrences range in elevation from 400 to 1,600 feet (Table 1).

Species associated with smooth lessingia include bigberry manzanita (*Arctostaphylos glauca*), common yarrow (*Achillea millefolium*), dwarf plantain

(*Plantago erecta*), golden yarrow (*Eriophyllum confertiflorum*), gypsum springbeauty (*Claytonia gypsophiloides*), hayfield tarweed (*Hemizonia congesta*), junegrass (*Koeleria macrantha*), miner's lettuce (*Claytonia perfoliata*), purple needlegrass (*Stipa* [*Nassella*] *pulchra*), serpentine linanthus (*Linanthus ambiguus*), serpentine sunflower (*Helianthus bolanderi*), streambank springbeauty (*Claytonia parviflora*), and yellow star thistle (*Centaurea solstitialis*) (U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2006).

**Table 1.** Habitat Associations for Smooth Lessingia

Land Cover Type	Habitat Designation	Habitat Parameters	Percent Suitable	Rationale
Serpentine Bunchgrass Grassland	Primary	In areas with low vegetation cover, at 400 to 1,600 feet elevation	Unknown, but probably high	California Natural Diversity Database 2006
Serpentine Rock Outcrop	Primary	at 400 to 1,600 feet elevation	Unknown, but probably high	California Natural Diversity Database 2006

## Population Ecology

The ecology and demography of smooth lessingia is unknown and remains unstudied. Population size appears to vary considerably between occurrence sites. Four populations had fewer than 200 individuals, whereas three other populations were reported to contain tens of thousands of plants (California Natural Diversity Database 2006). Estimates of population density at two sites were 10-20 plants per square meter and 40–60 plants per square meter (California Natural Diversity Database 2006). Table 2 shows key seasonal periods for the species.

**Table 2.** Key Seasonal Periods for Smooth Lessingia

	Jan	Feb	March	April	May	June	July	Aug	Sep	Oct	Nov	Dec
Germination	✓	✓	✓	✓								✓
Flowering							✓	✓	✓	(✓)	(✓)	
Fruiting								✓	✓	✓	✓	✓
Seed Dispersal	✓								✓	✓	✓	✓

Note: Periods in parentheses are atypical.

## Population Status and Trends

**Global:** *Unknown* (California Natural Diversity Database 2006)

**State:** *Unknown* (California Natural Diversity Database 2006)

**Within Study Area:** *Unknown* (California Natural Diversity Database 2006)

All documented occurrences of smooth lessingia are presumed to be extant (California Natural Diversity Database 2006).

## Threats

Reported threats to populations of smooth lessingia in the study area include cattle grazing, foot traffic (trampling), competition from invasive exotic plants, and road and trail maintenance (California Natural Diversity Database 2006).

## Data Characterization

Only 8 occurrences provide substantial information on the habitat in which the species has been found, but the available information is not likely to adequately characterize the species' habitat requirements. Very little data is available on the species' population biology, and no data is available on the management needs of the species. More information is also needed on threats to this species in the study area.

## Existing Conservation Actions in the Study Area

There are no conservation actions in the study area that are focused on the conservation of smooth lessingia.

## Modeled Habitat Distribution in Study Area

### Model Description

#### Model Assumptions

Suitable habitat for smooth lessingia is defined as serpentine bunchgrass grassland and serpentine rock outcrops between 0 and 2,000 feet in elevation on slopes with all degrees of steepness. Potential ecoregions include the Fremont-Livermore Hills and Valleys, Santa Clara Valley, Leeward Hills, Santa Cruz Mountains, Western Diablo Range, and Diablo Range.

## Rationale

Smooth lessingia is restricted to serpentine rock outcrops, serpentine roadcuts, and sparsely-vegetated serpentine grassland below 2,000 feet (California Natural Diversity Database 2006).

## Model Results

Modeled potential habitat for smooth lessingia is shown in Figure 2. The habitat is concentrated in the hills east of the Santa Clara Valley floor and north of Anderson Reservoir, and in scattered areas dominated by serpentinite-derived soils in the foothills of the Santa Cruz Mountains to the west of the valley floor. All of the known occurrences are mapped in Figure 2, and are found on modeled habitat (note that in some cases the modeled habitat is smaller than the size of the symbols in Figure 2).

## Metcalf Canyon Jewelflower (*Streptanthus albidus* ssp. *albidus*)

### Legal Status

**State:** California Native Plant Society 1B.1<sup>1</sup>

**Federal:** Endangered (U.S. Fish and Wildlife Service 1995)

**Critical Habitat:** None

**Recovery Planning:** *Recovery Plan for Serpentine Soil Species of the San Francisco Bay Area* (U.S. Fish and Wildlife Service 1998)

© R. Bittman and CNPS

### Taxonomy

Metcalf Canyon jewelflower (*Streptanthus albidus* ssp. *albidus*) was first described by Edward Greene in 1887 (Greene 1887). It was grouped into the subgenus *Euclisia* and changed status with the subgenus. *Euclisia* became its own genus (Greene 1904) until Jepson (1925) moved it back to subgenus status. Jepson (1925) considered Metcalf Canyon jewelflower to be a subspecies of *S. glandulosus*. Kruckberg (1958) determined that *S. albidus* ssp. *albidus* was so distinct both morphologically and based on geologic restrictions that he recognized this species as separate from *S. glandulosus* and divided it into *S. albidus* ssp. *albidus* and *S. albidus* ssp. *peramoenus* (most beautiful jewelflower, another taxa covered by this Plan). These divisions are still recognized as accurate (Integrated Taxonomic Information System 2001; U.S. Fish and Wildlife Service 1998). Metcalf Canyon jewelflower is in the Brassicaceae, or mustard family. The only *Streptanthus* species likely to grow in the same area as Metcalf Canyon jewelflower is its close relative, most beautiful jewelflower, which is distinguished by its dark purple sepals.

### Description

Descriptions of the species' physical characteristics can be found in Buck et al. (1993), Corelli and Chandik (1995), and U.S. Fish and Wildlife Service (1998). Metcalf Canyon jewelflower is a wiry annual herb up to three feet tall possessing small flowers along the stem with white petals with purple veins. It has bristly hairs at the base and glaucous stems and leaves (U.S. Fish and Wildlife Service 1998).

<sup>1</sup> 1B means rare, threatened, or endangered in California and elsewhere; 0.1 means seriously endangered in California.

## Distribution

### General

The range for Metcalf Canyon jewelflower is highly restricted and lies completely within Santa Clara County, extending approximately 20 miles from San José south to Anderson Lake (Figure 1; U.S. Fish and Wildlife Service 1998; California Native Plant Society 2006). Its current range is thought to be the same as its historic range (U.S. Fish and Wildlife Service 1998).

## Occurrences within the Study Area

### Historical

There are four historic reports of Metcalf Canyon jewelflower (California Natural Diversity Database 2006). One occurrence (California Natural Diversity Database occurrence #6) from 1895 may actually be a different species of *Streptanthus*. The second historic occurrence (#5) documented in 1937 has likely been extirpated because it is located in an area now covered by Anderson Lake. A third occurrence (#11) first documented in 1980 at Tulare Hill and updated again in 1995, was extirpated when the plants were covered by fill during construction of a housing development. A fourth occurrence was documented in Gilroy along Llagas Avenue in 1957 and has not been reported since (#16). There is some taxonomic uncertainty about this occurrence (U.S. Fish and Wildlife Service 1998).

### Extant

Eleven occurrences of Metcalf Canyon jewelflower in Santa Clara County are presumed extant (California Natural Diversity Database 2006), 10 of which are within the study area. Most of the occurrences are on the east side of Santa Clara Valley along U.S. 101 (Figure 2).

There are four occurrences on the west side of U.S. 101: CNDDDB occurrence numbers 6, 17, 19, and 21. CNDDDB occurrence 6 is located near Lexington Reservoir, is on Santa Clara County Parks land, and is outside the study area. Occurrence 17 is located on private land in San Jose and is assumed extant by the CNDDDB. Occurrence 19 is on Communication Hill in San Jose and is adjacent to an active quarry. This occurrence is expected to be impacted by activities not covered by this Plan. Occurrence 21 is a non-specific reference from 1992 and is located on private property.

The remaining seven occurrences are found on the eastern side of U.S. 101. CNDDDB occurrence numbers 18 and 20 are located on Type I open space. Occurrence number 15 is located near the Silver Creek Valley Country Club golf course. Occurrence numbers 8 and 4 are located in the Coyote Ridge area and are the two occurrences most likely to be impacted by SCVWD activities on the

Coyote Canal. Occurrence number 8 is located on Type 3 open space and occurrence 4 is located on private property. Occurrences 2 and 12 are also located on private property in the Coyote Ridge area.

## Natural History

### Habitat Requirements

Metcalf Canyon jewelflower is a serpentine endemic that can be found between 200 and 1,200 feet in elevation. It grows in serpentine grasslands and on serpentine outcrops and road cuts that have little soil development and are surrounded by grasslands (California Natural Diversity Database 2005; U.S. Fish and Wildlife Service 1998; Table 1). Commonly associated species are California sage (*Artemisia californica*), California poppy (*Eschscholzia californica*), foothill deer vetch (*Acmispon [Lotus] humistratus*), wild oats (*Avena fatua*) and a variety of other rare plants such as most beautiful jewelflower (*Streptanthus albidus* ssp. *peramoenus*), and Santa Clara Valley dudleya (*Dudleya abramsii* ssp. *setchellii*) (U.S. Fish and Wildlife Service 1998).

**Table 1.** Habitat Associations for Metcalf Canyon Jewelflower

Land Cover Type	Habitat Designation	Habitat Parameters	Percent Suitable	Rationale
Serpentine Bunchgrass Grassland	Primary habitat	Rocky outcrops and roadcuts with little soil development; 200–1,200 feet	High	U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2006; California Native Plant Society 2006
Serpentine Rock Outcrop/Barrens	Primary habitat	200–1,200 feet	High	U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2006; California Native Plant Society 2006

### Population Ecology

Very little is known about its life history stages and reproductive biology (U.S. Fish and Wildlife Service 1998). Metcalf Canyon jewelflower is closely related to most beautiful jewelflower (McCarten 1992 in U.S. Fish and Wildlife Service 1998). Based on chloroplast DNA studies, there is evidence that Metcalf Canyon jewelflower has recently evolved (neoendemic) (Mayer and Soltis 1994 in U.S. Fish and Wildlife Service 1998). Furthermore, studies have shown that there are genetic differences among the various populations of Metcalf Canyon jewelflower, which suggests that all populations are important to monitor and protect (Mayer et al. 1994 in U.S. Fish and Wildlife Service 1998). Key seasonal periods for this species are shown in Table 2.

Herbivory has been recorded on other species of *Streptanthus* in central Texas by white-tailed deer and insects such as pierid butterfly caterpillars. These herbivores can have substantial negative effects on plant growth, survival, reproduction, and population dynamics (Zippin 1997).

**Table 2.** Key Seasonal Periods for Metcalf Canyon Jewelflower

	Jan	Feb	March	April	May	June	July	Aug	Sep	Oct	Nov	Dec
Germination	✓	✓	✓							✓	✓	✓
Flowering				✓	✓	✓	✓					
Fruiting						✓	✓	✓	✓			
Seed Dispersal						✓	✓	✓	✓	✓	✓	✓

## Population Status and Trends

**Global:** Declining (NatureServe 2006)

**State:** Declining (NatureServe 2006)

**Study Area:** Unknown

Nine populations have been documented as having a total of 20,000 to 25,000 plants (McCarten 1992 in U.S. Fish and Wildlife Service 1998). The current status of these populations is unknown. Road construction through serpentine areas may create habitat for this species by exposing serpentine rock that can be colonized by Metcalf canyon jewelflower.

## Threats

Urban development and cattle grazing pose the greatest threats to Metcalf Canyon jewelflower (U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2006). Urban development has already eliminated at least one known population and planned developments have threatened others. Even if no direct impacts on these plants are anticipated, construction activities, human disturbance, and habitat fragmentation can all have a negative impact (U.S. Fish and Wildlife Service 1998). Cattle may trample and eat plants, leading to a decline in the overall population as well as to a decline in the soil seed bank if plants are eliminated prior to setting seed (U.S. Fish and Wildlife Service 1998). Plants found on steep roadcuts or large rock outcrops are likely inaccessible to cattle. Garbage dumping and off-road motorcycles are additional threats (U.S. Fish and Wildlife Service 1998). One site located next to an active quarry could be impacted by quarry-related activities (U.S. Fish and Wildlife Service 1998, California Natural Diversity Database 2006). At another site, expansion of a landfill poses a threat (California Natural Diversity Database 2006). Road maintenance and construction could also impact populations which occur on or near roadcuts and those found along roads (U.S. Fish and Wildlife Service 1998).

## Data Characterization

Very little information about the reproductive biology or demography of Metcalf Canyon jewelflower is available (U.S. Fish and Wildlife Service 1998).

## Existing Conservation Actions in the Study Area

There are no known conservation actions in the study that are focused on Metcalf Canyon jewelflower. However, conservation actions directed at other serpentine species may benefit Metcalf Canyon jewelflower. For example, recent acquisition of mitigation land on Coyote Ridge by the Santa Clara Valley Transportation Authority is protecting suitable habitat for Metcalf Canyon jewelflower. Livestock grazing along Coyote Ridge designed to maintain and improve habitat for the food and nectar plants of Bay checkerspot butterfly (see the account for Bay checkerspot butterfly for more information) may indirectly benefit Metcalf canyon jewelflower by reducing the density and biomass of exotic grasses and herbs that may compete with the jewelflower.

The U.S. Fish and Wildlife Service suggests that surveys should be conducted at the Tulare Hill site to see if appropriate habitat still exists for potential repopulation efforts (U.S. Fish and Wildlife Service 1998).

## Modeled Habitat Distribution in Study Area

### Model Description

#### Model Assumptions

Suitable habitat for Metcalf Canyon jewelflower is defined as serpentine bunchgrass grassland and serpentine rock outcrops between 0 and 1,200 feet in elevation on slopes with all degrees of steepness. Potential ecoregion subsections include the Fremont-Livermore Hills and Valleys, Leeward Hills, Western Diablo Range, and Diablo Range.

#### Rationale

Metcalf Canyon jewelflower is restricted to serpentine rock outcrops and sparsely-vegetated serpentine grassland below 1,200 feet (U.S. Fish and Wildlife Service 1995, 1998).

## Model Results

Figure 2 shows the modeled potential habitat for Metcalf Canyon jewelflower. The habitat is primarily located in the hills east of the Santa Clara Valley floor and north of Anderson Reservoir, and in scattered areas dominated by serpentinite-derived soils in the foothills of the Santa Cruz Mountains to the west of the valley floor. All of the known occurrences are found on modeled habitat (see Figure 2; note that in some cases the modeled habitat is smaller than the size of the symbols on the map).

## Most Beautiful Jewelflower (*Streptanthus albidus* ssp. *peramoenus*)

### Legal Status

**State:** California Native Plant Society  
List 1B.2<sup>1</sup>

**Federal:** Special Concern

**Critical Habitat:** None

**Recovery Planning:** *Recovery Plan for  
Serpentine Soil Species of the San  
Francisco Bay Area* (U.S. Fish and  
Wildlife Service 1998)

© Benjamin C. Hammett,  
California Academy of Sciences

### Taxonomy

Most beautiful jewelflower (*Streptanthus albidus* ssp. *peramoenus*) was first described by Edward Greene in 1887 as *Streptanthus peramoenus* (Greene 1887). It was grouped into the subgenus *Euclisia* and changed status with the subgenus. *Euclisia* became its own genus (Greene 1904) until Jepson (1925) moved it back to subgenus status. Jepson (1925) considered most beautiful jewelflower to be a part of *S. glandulosus*. Kruckberg (1958) determined that *S. albidus* was distinct both morphologically and based on geologic restrictions that he recognized this species as separate from *S. glandulosus* and divided it into *S. albidus* ssp. *albidus* (Metcalf Canyon jewelflower, another taxa covered by this Plan) and *S. albidus* ssp. *peramoenus*.

The taxonomic status of this species is currently under debate. Recent genetic studies raise the possibility that the species concept for most beautiful jewelflower may be broadened by including additional populations of plants currently assigned to other *Streptanthus* species (Mayer et al. 1994; Mayer and Soltis 1999). However, the U.S. Fish and Wildlife Service concluded that current research affirms the uniqueness of this taxon (1998). Therefore, its regulatory status is unlikely to be affected by ongoing taxonomic research. Most beautiful jewelflower is in the mustard family (Brassicaceae).

### Description

Descriptions of the species' physical characteristics can be found in Kruckeberg (1958) and Buck et al. (1993). The species is an annual herb up to 32 inches tall with fleshy and glaucous stems and leaves. The flowers have lilac-lavender

<sup>1</sup> 1B means rare, threatened, or endangered in California and elsewhere; .2 means fairly endangered in California.

sepals and purplish petals. The subspecies is distinguished from the closely-related Metcalf Canyon jewelflower by its lilac-lavender sepals. (Metcalf Canyon jewelflower has greenish-white sepals which are tinged with purple at their base.)

## Distribution

### General

Most beautiful jewelflower is endemic to the northern South Coast Ranges of Contra Costa, Alameda, and Santa Clara Counties (Figure 1) (California Native Plant Society 2006; California Natural Diversity Database 2008). If other species of *Streptanthus* were to be incorporated into the same taxon as most beautiful jewelflower, its range would be expanded to include Mount Hamilton and portions of the Mount Hamilton range, as discussed below.

### Occurrences within the Study Area

There are 39 occurrences of the most beautiful jewelflower in the study area, 35 of which are listed with the California Natural Diversity Database (2012). The other occurrences are known to occur on Santa Clara County Parks and on or adjacent to Santa Clara Valley Water District lands. All occurrences are believed to be extant. Most are of high precision and may be accurately located. Two other occurrences are known that are not recorded in the California Natural Diversity Database; two populations of the dark-flowered form that occur on Mount Hamilton (Mayer et al. 1994; not mapped). Other collections of *Streptanthus glandulosus* from the Mount Hamilton Range (CalFlora 2006) may also represent the dark-flowered form of most beautiful jewelflower.

Occurrences of the species are located in the vicinity of Anderson Lake, Kirby Canyon, and Metcalf Canyon east of Highway 101. West of Highway 101, occurrences are documented in the New Almaden Historic Landmark District, in the vicinity of Coyote Peak and Santa Teresa County Park, in the vicinity of Calero Reservoir County Park and Laurel Hill, in the vicinity of Chesbro Reservoir, and south of Morgan Hill and north of the Carlyle Hills. These occurrences fall on both Santa Clara County land, principally in County parks, and on private land. Two of the occurrences on private land are owned by IBM (California Natural Diversity Database 2006). According to the U.S. Fish and Wildlife Service, IBM intends to preserve these occurrences (U.S. Fish and Wildlife Service 1998).

## Natural History

### Habitat Requirements

Most beautiful jewelflower is almost entirely restricted to serpentinite outcrops or soils derived from serpentinite (Table 1). Serpentine soils are deficient in calcium, but serpentine-endemic jewelflower populations are capable of growing under low levels of calcium (Kruckeberg 1954). Most beautiful jewelflower is generally found in grasslands dominated by native perennial grasses or in open grasslands dominated by nonnative annual grasses with relatively low cover. It is also found on rock outcrops or grassy openings in serpentine chaparral or where serpentine grassland or chaparral habitats transition to oak woodland and it can occur on serpentine roadcuts and road surfaces. It has been found at elevations ranging from 360 to 3280 feet.

Species commonly associated with most beautiful jewelflower include native species such as bigberry manzanita (*Arctostaphylos glauca*), buck brush (*Ceanothus cuneatus*), California poppy (*Eschscholzia californica*), dwarf plantain (*Plantago erecta*), purple needlegrass (*Stipa* [*Nasella*] *pulchra*), as well as non-natives including foxtail chess (*Bromus madritensis* ssp. *rubens*), pampas grass (*Cortaderia jubata*), slender wild oat (*Avena barbata*), soft chess (*Bromus hordeaceus*), and wild oat (*Avena fatua*) (California Natural Diversity Database 2006).

At least one population of the dark-flowered form of most beautiful jewelflower occurs on non-serpentine habitat at Henry Coe State Park (Mayer et al. 1994). A population found in Arroyo Hondo in Alameda County occurs in non-serpentine habitat, where it occurs on rock outcrops in coastal sage scrub dominated by California sagebrush (*Artemisia californica*), bush monkeyflower (*Mimulus aurantiacus*), and golden-yarrow (*Eriophyllum confertiflorum*). Bristly jewelflower (*Streptanthus glandulosus*), to which most beautiful jewelflower is closely related, also has serpentine-tolerant and serpentine-intolerant populations (Kruckeberg 1951).

**Table 1.** Habitat Associations for Most Beautiful Jewelflower

Land Cover Type	Habitat Designation	Habitat Parameters	Habitat Suitability	Rationale
Serpentine bunchgrass grassland	Primary	Shallow soils or where non-native species have low relative cover; 360 to 3280 feet	Moderate	Kruckeberg 1954
Serpentine rock outcrop/barrens	Primary	Includes roadcuts; 360 to 3280 feet	High	Competition from non-natives in serpentine grassland frequently restricts this species to shallow soils near serpentine rock outcrops (Green 2004)
Mixed serpentine chaparral	Primary	Grassy openings; 360 to 3280 feet		Kruckeberg 1954; California Natural Diversity Database 2006
Rock outcrop	Secondary	360 to 3280 feet	Low to Moderate	Non-serpentine populations of the species may be found here (Mayer et al. 1994; California Natural Diversity Database 2006)

## Population Ecology

Population sizes of most beautiful jewelflower vary from less than fifty to tens of thousands (California Natural Diversity Database 2006). Most beautiful jewelflower appears to be insect pollinated. Kruckeberg (1957) reported that members of the *Streptanthus glandulosus* complex, including most beautiful jewelflower, were incapable of self-pollination, and he had observed bees, butterflies, and beetles visiting the flowers. Bees have been observed to be the primary floral visitors in other outcrossing *Streptanthus* species (Dieringer 1991; Preston 1994), although flies and butterflies also visit *Streptanthus* flowers (Moldenke 1976). *Streptanthus* flowers appear to be self-fertile, but a combination of spatial and temporal separation of the stamens and receptive stigmas prevents self-pollination (Preston 1991).

No information on herbivory of most beautiful jewelflower is available; however, other jewelflower species are eaten by herbivorous insects (e.g., Zippin 1997). The larvae of pierid butterflies commonly eat jewelflower leaves, flowers, and developing fruit (Shapiro 1981a, 1981b, 1984; Karban and Courtney 1987; Zippin 1997). The flowers are also eaten by sap beetles and flea beetles (Shapiro 1981a; Karban and Courtney 1987; Preston 1991; Zippin 1997). Some species of serpentine-endemic jewelflowers appear to have “egg-mimics” on the leaves, which inhibit some pierid species from laying eggs there (Shapiro 1981a). Key seasonal periods for the species are shown in Table 2.

**Table 2.** Key Seasonal Periods for Most Beautiful Jewelflower

	Jan	Feb	March	April	May	June	July	Aug	Sep	Oct	Nov	Dec
Germination	✓	✓	✓							✓	✓	✓
Flowering			✓	✓	✓	✓						
Fruiting					✓	✓	✓					
Seed Dispersal					✓	✓	✓	✓	✓	✓	✓	✓

## Population Status and Trends

**Global:** Declining (NatureServe 2006)

**State:** Declining (NatureServe 2006)

**Study Area:** Unknown

Population trends for most beautiful jewelflower are unknown in the study area. There are no known populations in the study area that have been extirpated. Road construction through serpentine areas may create habitat for this species by exposing serpentine rock that can be colonized by most beautiful jewelflower (S. Weiss pers. comm.). However, the small number of populations known, and the known threats to these populations, suggest that protection and management of populations is necessary to ensure the species' long-term survival (U.S. Fish and Wildlife Service 1998).

## Threats

Potential threats to most beautiful jewelflower include cattle grazing, competition from invasive exotic species (notably yellow star thistle [*Centaurea solstitialis*]), and habitat loss from residential development and road construction (California Natural Diversity Database 2006; California Native Plant Society 2006). Non-native species invasion of serpentine grassland threatens occurrences in the study area (Green 2004). Grazing threatens some populations in the study area west of Highway 101 (U.S. Fish and Wildlife Service 1998). Additional threats in the study area include rooting by feral pigs and disturbance from landfill operations.

## Data Characterization

A species profile for most beautiful jewelflower is provided in the *Recovery Plan for Serpentine Soil Species of the San Francisco Bay Area* (U.S. Fish and Wildlife Service 1998). The main sources of general information on most beautiful jewelflower are *The Jepson Manual* (Buck et al. 1993) and the California Native Plant Society (2001). Specific information on the systematics of most beautiful jewelflower is found in Mayer et al. (1994) and in Mayer and Soltis (1999). Specific observations on habitat and plant associates, threats, and

other factors are provided in the recovery plan and in the California Natural Diversity Database (2006). There are relatively many occurrence records for this species, and all are presumed extant and with excellent or good geographic accuracy. Very little information about the reproductive biology or demography of most beautiful jewelflower is available (U.S. Fish and Wildlife Service 1998), but the species' ecology can be inferred from study of other *Streptanthus* species.

## Existing Conservation Actions in the Study Area

There are no known conservation actions in the study that are focused on most beautiful jewelflower. However, conservation actions directed at other serpentine species may benefit the species. For example, recent acquisition of mitigation land on Coyote Ridge by the Santa Clara Valley Transportation Authority is protecting suitable habitat for most beautiful jewelflower. Livestock grazing along Coyote Ridge designed to maintain and improve habitat for the food and nectar plants of Bay checkerspot butterfly (see the account for Bay checkerspot butterfly for more information) may indirectly benefit most beautiful jewelflower by reducing the density and biomass of exotic grasses and herbs that may compete with the jewelflower. Acquisition by the Santa Clara Valley Open Space Authority south of Calero Reservoir is also protecting several occurrences of this species (Cañada de Oro Open Space Preserve). Long-term plans by the Santa Clara County Parks and Recreation Department to reintroduce livestock grazing in Santa Teresa County Park may also benefit most beautiful jewelflower by reducing competition with exotic grasses and herbs.

## Modeled Habitat Distribution in Study Area

### Model Description

#### Model Assumptions

1. Primary habitat is defined as serpentine bunchgrass grassland, serpentine rock outcrops/barren, and mixed serpentine chaparral between 0 and 3,500 feet elevation on slopes with all degrees of steepness.
2. Secondary habitat is defined as non-serpentine rock outcrops between 0 and 3,500 feet elevation on slopes with all degrees of steepness.

Potential ecoregion subsections for both habitat types are the Fremont-Livermore Hills and Valleys, Santa Clara Valley, Leeward Hills, Santa Cruz Mountains, Western Diablo Range, and Diablo Range.

## Rationale

Most beautiful jewelflower is almost entirely restricted to serpentinite outcrops or soils derived from serpentinite (Kruckeberg 1954). The species is found within serpentine grasslands and serpentine chaparral, primarily in grassy openings or at the boundary with oak woodlands (U.S. Fish and Wildlife Service 1998; California Natural Diversity Database 2006). Most beautiful jewelflower is less commonly found in non-serpentine soils on rock outcrops (Mayer et al. 1994; California Natural Diversity Database 2006).

## Model Results

Modeled potential habitat for most beautiful jewelflower is shown in Figure 2. The habitat is concentrated in the hills east of the Santa Clara Valley floor and north of Anderson Reservoir, and in scattered areas dominated by serpentinite-derived soils in the foothills of the Santa Cruz Mountains to the west of the valley floor. Most of the secondary habitat is located in areas that are smaller than the minimum mapping unit of the land cover mapping, so very little of it shows on the habitat model. However, all of the known occurrences are found on modeled habitat (see Figure 2, note that in some cases the modeled habitat is smaller than the size of the symbols on the map).

# Nitrogen Deposition Contribution Estimates in Santa Clara County for the Santa Clara Valley Habitat Plan

## Executive Summary

Atmospheric nitrogen deposition is a complex process by which reactive chemical species of nitrogen (N)—nitrogen oxides (NO<sub>x</sub>), ammonia (NH<sub>3</sub>), and their reaction products—are deposited onto surfaces and enter ecosystems as N-fertilizer. N-deposition estimates (from varied studies) for the Santa Clara Valley range from 8–20 kilograms of nitrogen per hectare per year (kg-N/ha/y).<sup>1</sup> In Santa Clara County, N-deposition threatens serpentine grasslands that support numerous covered species, including the threatened Bay checkerspot butterfly (*Euphydryas editha bayensis*). The added N allows nutrient-poor serpentine soils to be invaded by non-native annual grasses that displace the native forbs that provide caterpillar food and adult nectar for the butterfly. N-deposition is the largest indirect impact of urban development on the serpentine grassland ecosystem.

The effects of N-deposition on non-serpentine annual grasslands and the grassland understory of oak woodlands are similar to those on serpentine grassland—increased annual grass growth displaces native forbs. Non-serpentine annual grasslands and oak woodlands in the study are extensive (310,875 acres, or 60% of the study area<sup>2</sup>), so these adverse effects could be widespread.

For this study, ICF International (ICF) analyzed nitrogen deposition using several modeling approaches in order to estimate the sources that contribute to deposition in the study area for the Santa Clara Valley Habitat Plan (Habitat Plan). In order to estimate contributions from individual roadways and to assess the increase in deposition due to increases in traffic, Gaussian models for a limited domain were applied to receptors centered on serpentine habitat that supports populations of the threatened Bay checkerspot butterfly (called *habitat areas* in this report). Serpentine habitat receptors were selected because of the sensitivity of these areas to N-deposition. The much more complex Community Multiscale Air Quality modeling system (CMAQ) was also used to simulate the area's more complex nitrogen transport processes, and, using the Particle and

---

<sup>1</sup> One hectare = 2.47 acres. 1 kg-N/ha/y = 0.93 lb-N/acre/y.

<sup>2</sup> The “study area” as referenced in this report includes State Parks lands.

Precursor Tagging Methodology (PPTM) source apportionment technique, to estimate contributors to deposition on a broader scale. The Gaussian models are relatively simple to apply but give results only within a few kilometers of the sources being modeled. The Gaussian models simulate the complex atmospheric chemistry that affects the deposition of nitrogen. The CMAQ model treats the complex transport, chemistry, and deposition processes required to simulate nitrogen deposition in detail. Because development of databases for CMAQ is a large undertaking, existing databases were acquired from the California Air Resources Board (CARB) and from the Bay Area Air Quality Management District (BAAQMD).

Estimates of overall deposition based on observations of nitrogen dioxide (NO<sub>2</sub>) concentration and modeling using CMAQ both give estimates of total nitrogen deposition of about 6 kg-N/ha/y, which is consistent with other studies such as Weiss (2006). In general, modeling estimates may be biased high or low relative to estimates made on other bases. Given modeling estimates in reasonable agreement with other methods, however, modeling methods can be used in order to compare effects of different sources in a relative sense. Modeling with CMAQ also provides estimates of increases in deposition using emissions extrapolated to future years. Modeling with Gaussian models, while not providing an estimate of overall deposition, provides an estimate of deposition from individual roadways and the increases in deposition from those roadways with emissions extrapolated to the future.

Reliable future year emissions were not available when the CMAQ modeling was conducted. Future year emissions were extrapolated from the base year based on population growth which may overestimate emissions. Based on the CMAQ modeling, total nitrogen deposition in the Bay checkerspot butterfly habitat areas could increase to 8 kg-N/ha/y in 2035 and almost 10 kg-N/ha/y in 2060 using the extrapolated emissions. Using extrapolated emissions, Gaussian modeling indicates that contributions to nitrogen deposition from major roadways could increase by almost a factor of two by 2030 and by more than a factor of 4 by 2060.

The amount that various sources contribute to deposition was assessed with different modeling approaches. The most complete of these methods was the use of the PPTM tagging approach in CMAQ. In addition, however, Gaussian modeling provided estimates of the relative contributions of several major roadways to nitrogen deposition.

In the base year, the CMAQ PPTM simulation attributes 30% of the total nitrogen deposition to mobile sources within the study area. Another 16% of the nitrogen deposition comes from stationary sources in the study area. Therefore, 46% of nitrogen deposition on the habitat areas comes from existing development and vehicle traffic generated locally within the study area. The remainder of Santa Clara County contributes 17% of the nitrogen deposition while the remaining Bay Area counties account for about 11% of the deposition. The CMAQ simulation indicates that the remaining 26% of the N-deposition comes from anthropogenic emissions in the remainder of the modeling domain

(i.e., most of the remainder of California other than Bay Area counties and a portion of Nevada), initial and boundary concentrations (i.e., effects from outside of the modeling domain), and biogenic emissions within the Bay Area counties. Impacts of nitrogen deposition from Morgan Hill and Gilroy were not explicitly identified in our modeling, but are part of the contribution referred to as the remainder of Santa Clara County. In the emissions inventory used to prepare emissions for CMAQ, municipalities are not identified separately from the county in which they are located. Estimates of emissions for Morgan Hill and Gilroy were made based on the overlap of boundaries of these cities with grid cells in the modeling domain (see Table E-15). Because grid cells resolve emissions only to areas measuring 16 square kilometers ( $\text{km}^2$ ), this is necessarily an approximation. However, based on these estimates, Gilroy emissions make up 2% of the Santa Clara County  $\text{NO}_x$  emissions, Morgan Hill emissions make up 3% of the Santa Clara County  $\text{NO}_x$  emissions, San José emissions make up 79% of the Santa Clara County  $\text{NO}_x$  emissions, and the remainder of Santa Clara County emissions make up (16%) of the county  $\text{NO}_x$  emissions. (Note that these relative amounts of emissions in Santa Clara County should not be confused with the estimates of contributions to deposition that are derived from the CMAQ model results.) It is reasonable to assume that the contribution to nitrogen deposition from Gilroy and Morgan Hill would be roughly in proportion to their emissions. Of the 17% contribution to nitrogen deposition noted for the remainder of Santa Clara County, therefore, we could expect Gilroy to make up about 1.5% (9% of 17%) and Morgan Hill to make up about 2.7% (16% of 17%).

Increases in nitrogen deposition in future years were simulated for Bay Area counties. The emissions data files used in this study were available with only grid cell-by-grid cell emissions in the part of the domain outside of the Bay Area. Because county-by-county emissions projections are not readily made for files in this format, future-year emissions extrapolations were not made for the remainder of the domain. Within the Bay Area, future emissions were extrapolated from the base year based on population growth which does not taken into account expected improvements in emission control technology for motor vehicles. The extrapolations could therefore overestimate the emissions in the future years. Contribution of mobile source emissions in the habitat area are estimated to increase by about 0.6 kg-N/ha/y in 2035 over the base year and by another 0.5 kg-N/ha/y in 2060. The San José contribution to nitrogen deposition in the habitat areas is estimated to be 38% in 2035. Gaussian modeling of major roadways near the habitats indicates an increase in nitrogen deposition of about 0.25 kg-N/ha/y in 2030 over the base year (a 4% increase in total deposition). The increase in 2060 relative to 2030 could be from 0.4 kg-N/ha/y to more than 1 kg-N/ha/y (at the Hale Avenue site) depending on location (a 7% to 17% increase in total deposition).

Only growth in emissions in Bay Area counties was considered in the CMAQ PPTM simulations because future-year emissions were not available for the remainder of the modeling domain. Estimates of future-year nitrogen deposition could be even higher if growth in the rest of the state were included. Gaussian modeling was limited to an area in the immediate vicinity of the habitats due to the limitations in scale of this type of model.

The contribution of emissions outside of the study area but within Santa Clara County are estimated to grow from 1.1 kg-N/ha/y in the base year to 1.5 kg-N/ha/y using emissions extrapolated to 2035 and 1.7 kg-N/ha/y using emissions extrapolate to 2060. The contribution of emissions from all other Bay Area counties are estimated to grow from 0.7 kg-N/ha/y in the base year to 0.9 kg-N/ha/y using emissions extrapolated to 2035 and 1.0 kg-N/ha/y extrapolated to 2060.

## Background

Urban development and rural development covered under the Habitat Plan are expected to increase air pollutant emissions due to an increase in passenger and commercial vehicle trips and other new industrial and nonindustrial sources. Emissions from these sources are known to increase airborne reactive nitrogen, of which a certain amount is converted into forms that can fall to the ground as depositional nitrogen.

It has been shown that increased nitrogen in serpentine soils can favor the growth of nonnative annual grasses over native serpentine species (Weiss 1999, 2006). These nonnative species, if left unmanaged, can overtake the native serpentine species, including dwarf plantain (*Plantago erecta*), the primary host plant for Bay checkerspot butterfly, a threatened species and a key covered species in the Habitat Plan. Nonnative plants may also compete with native plants for water, nutrients, light, and sites for germination, crowding out plants covered by the Habitat Plan (e.g., Metcalf Canyon jewelflower [*Streptanthus albidus* ssp. *albidus*], most beautiful jewelflower [*Streptanthus albidus* subsp. *peramoenus*], and fragrant fritillary [*Fritillaria liliacea*]).

The amount of available nitrogen in Santa Clara County serpentine grasslands is a function of biological uptake and generation, abiotic chemical transformation mechanisms, and transport of chemical nitrogen compounds (known as chemical “species”) into and out of the region. Nitrogen transport within the region is likely to be a function of farming and agricultural processes and atmospheric deposition from point and mobile sources. This report documents how nitrogen is transported into and within the region by atmospheric processes. A special emphasis is placed on characterizing the upwind sources of nitrogen that ultimately deposit on the serpentine grasslands in the Habitat Plan study area. Progressively more complex modeling techniques are used to estimate the amount of nitrogen deposition likely to affect serpentine grasslands in the study area.

## Purpose

The primary purpose of this report is to quantify the expected increases in nitrogen deposition in Santa Clara County as a result of the urban and rural growth covered by the Habitat Plan to:

- 1) extrapolate changes in deposition rates over time; and
- 2) estimate the percentage of nitrogen deposition in the study area that results from air pollution emissions within the Habitat Plan study area, as opposed to air pollution that is transported from other regions to the study area.

The Habitat Plan addresses growth over a 50-year period in the cities of San José, Morgan Hill, Gilroy, and unincorporated Santa Clara County within the Habitat Plan study area (519,506 acres, approximately 62% of the county; see Figure 1-2 in the Habitat Plan).

A large fraction of the vehicle trips within the study area originate outside the study area. This report also quantifies expected increases in nitrogen deposition within the study area from projected growth outside the study area. Although this outside growth is not addressed by the Habitat Plan, it contributes to the cumulative impact of nitrogen deposition on habitats and covered species within the Habitat Plan study area. Knowing the expected increases in nitrogen deposition outside the study allows us to put the impacts of the Habitat Plan covered activities into the proper context of growth in the entire region.

Another purpose of this report is to link the deposition of nitrogen from mobile and point sources to impacts on natural communities and the covered species addressed by the Habitat Plan. This report therefore provides technical background for the impact analysis in Chapter 4 of the Habitat Plan. The report also provides technical justification for the approval of new local fees on public and private development to help fund the Habitat Plan.

## Summary of Past Analyses

Three recent quantitative assessments of anticipated nitrogen deposition on serpentine grassland in Santa Clara County have been conducted for local projects (CH2M Hill 2000; U.S. Fish and Wildlife Service 2001; City of San José 2007). These assessments used relatively rudimentary techniques for estimating nitrogen deposition that were appropriate for each project. These methods could not be used in our study because of the complexity (e.g., many mobile sources) and large area over which the covered activities in the Habitat Plan occur. Because of the time scale involved (50 years), the Habitat Plan also needs to put the nitrogen deposition impacts of its covered activities into the context of impacts that will occur outside the study area, something these projects did not assess. These past analyses are briefly described below for context.

### Metcalfe Energy Center

The Metcalfe Energy Center is a 600 MW natural gas-fired power plant built by the Calpine Corporation at the north end of Coyote Valley, adjacent to Tulare Hill, in the City of San José. The site is located on approximately 20 acres.

Construction of the plant and its associated transmission line, gas line, and water and wastewater lines began in 2002. The plant began operating in 2005.

Modeling of nitrogen deposition from the Metcalf Energy Center used the U.S. Environmental Protection Agency's (EPA) Industrial Source Complex—Short Term (ISCST3) model. The ISCST3 model was widely used at the time of the analysis. ISCST3 model does not account for the partitioning of nitrogen into gas phase versus aerosol species (Davis et al. 2003) which limits the applicability of the modeling results to determine relationships between nitrogen emissions and nitrogen deposition in Santa Clara County. Consequently, the Metcalf Energy Center model arrived at theoretically maximum nitrogen deposition levels by assuming complete and immediate conversion of nitrogen emissions to depositional nitrogen, overestimating the deposition of nitrogen from Metcalf Energy Center on adjacent serpentine grasslands, and underestimating the fraction of NO<sub>x</sub> emissions that would be deposited in other locations, including nonserpentine areas in the Central Valley (CH2MHill 2000; Don Ballanti pers. comm.; Edith Allen pers. comm.). Because this facility was a stationary source of emissions, its model was not appropriate for the analysis used in this report.

## Coyote Valley Research Park

The Coyote Valley Research Park is approximately 385 acres and is located in the North Coyote Valley, in the southern end of San José. The Coyote Valley Research Park is located immediately southwest of the Metcalf Energy Center. Development permits are currently in place to build out over six million square feet of office space.

The U.S. Fish and Wildlife Service (USFWS) quantitatively analyzed impacts of nitrogen deposition associated with the Coyote Valley Research Park (U.S. Fish and Wildlife Service 2001) based on the nitrogen deposition analysis conducted for the Metcalf Energy Center analysis described above. Based on this extrapolation, USFWS outlined a proposed quantitative regional impact analysis methodology (Nagano pers. comm.). As part of the analysis, USFWS made the following assumptions.

- **Extrapolation from power plant (Metcalf Energy Center) emissions to emissions from development is appropriate.** The USFWS method entails comparing NO<sub>x</sub> emissions from the CVRP with NO<sub>x</sub> emissions from the Metcalf Energy Center, and quantifying acreage affected on the basis of the comparison. Accordingly, if the CVRP were expected to emit twice as much NO<sub>x</sub> as the Metcalf Energy Center, twice the area of serpentine grassland affected by Metcalf Energy Center would be affected by the CVRP.
- **The modeling approach used for Metcalf Energy Center emissions is appropriate for current analyses.** The USFWS model assumes that all of the assumptions applied for the Metcalf Energy Center are also appropriate for application to the Coyote Valley Research Park, except as noted below.

- **Ammonia emissions from the Metcalf Energy Center can be excluded from the calculation of overall Metcalf Energy Center emissions in considering the relative contribution of development to nitrogen deposition.** In comparing expected emissions from the CVRP and the Metcalf Energy Center, USFWS did not include expected  $\text{NH}_3$  emissions.
- **A multiplier of two (2) applied to the expected CVRP emissions (as described in the first bullet above) can be used to account for local and regional contributions to nitrogen deposition.** Emissions from CVRP are expected to be relatively greater than emissions from the Metcalf Energy Center project due to contributions to nitrogen deposition from local development projects and regional use of U.S. Highway 101 (US 101). In making this comparison, the nitrogen emissions expected from the CVRP development were multiplied by 2 to account for regional use of US 101 and additional projects occurring in the region.
- **The same impact level should be applied to all critical habitat units in the county, regardless of location and habitat quality.** The USFWS analysis method assumed an equal distribution of impacts on some of the critical habitat in the county and did not account for likely differences in impacts based on location of critical habitat. For example, the Santa Teresa Hills are located west of US 101, and would therefore be expected to receive lower levels of nitrogen from increased traffic than Coyote Ridge (Kirby/Andersen critical habitat unit), as noted in the USFWS 2001 BCB critical habitat designation (66 FR 83, 21450).

In summary, the USFWS biological opinion quantifies the acreage of serpentine grassland expected to be affected by nitrogen deposition due to development of the CVRP by extrapolating from estimated impacts of the Metcalf Energy Center. The USFWS method compares extrapolated  $\text{NO}_x$  emissions from the CVRP (based on extrapolation of Metcalf Energy Center emissions) with  $\text{NO}_x$  emissions from the Metcalf Energy Center, and quantifying acreage affected on the basis of the comparison. In making this comparison, the nitrogen emissions expected from the CVRP development were multiplied by 2 to account for regional use of US 101 and additional projects occurring in the region.

USFWS quantified impacts from the CVRP on nearby Bay checkerspot butterfly (BCB) critical habitat units<sup>3</sup> (Kirby/Anderson, Santa Teresa, Morgan Hill, Kalana, and Tulare) but did not discuss impacts on other Bay checkerspot butterfly critical habitat in Santa Clara County.

## Coyote Valley Specific Plan

During development of the *Coyote Valley Specific Plan Draft Environmental Impact Report*, the City of San José was required to develop a quantitative assessment of nitrogen deposition impacts related to development of Coyote Valley. The methods and assumptions used in this analysis were based on the

---

<sup>3</sup> Bay checkerspot butterfly critical habitat units are serpentine grassland areas.

Metcalf Energy Center and Coyote Valley Research Park analyses described above. In this analysis, the impacts of nitrogen emissions associated with the Coyote Valley Specific Plan were estimated by comparing extrapolated nitrogen emissions from the Coyote Valley Specific Plan Area with the nitrogen emissions from Coyote Valley Research Park and then scaling the Coyote Valley Specific Plan emissions accordingly. A similar analysis was prepared to analyze potential impacts to serpentine grasslands due to increased nitrogen emissions from the Coyote Valley Specific Plan Area (City of San José 2007).

Only the three analyses described above have attempted to quantify impacts of nitrogen deposition on serpentine land covers in Santa Clara County. Of these three, only the Metcalf Energy Center analysis was an original analysis (i.e., was not extrapolated from pre-existing analyses). As described above, the Metcalf Energy Center analysis likely overestimated impacts from that project. Furthermore, newer models have since been developed and are replacing the ISCST3 model used in the Metcalf Energy Center analysis. Finally, the type and extent of impacts associated with the covered activities proposed in the Santa Clara Valley Habitat Plan are very different than those activities for which the Metcalf Energy Center Analysis was conducted. Therefore, an entirely new approach and analysis is needed to assess the nitrogen deposition impacts associated with implementing the covered activities of the Santa Clara Valley Habitat Plan.

## Background on Modeling Methods Considered for this Study

The goal of this study is to make quantitative estimates of nitrogen deposition to the Bay checkerspot butterfly habitat using established modeling techniques. There are several different techniques available to make such estimates. In the sections below we first give general descriptions of available techniques and then give a description of the techniques chosen for this study.

## Review of Common Air Quality Modeling Techniques and Nomenclature

In air quality literature, *source apportionment* refers to the process of determining the upwind source of pollutants in an air sample. Typically, one categorizes the methodology of source apportionment as either “receptor based” or “source based.”

In a receptor-based analysis, one uses an air quality sample obtained at the location of interest and back-calculates the upwind source using a statistical model such as a chemical mass balance (CMB) model. The CMB model is relatively easy to apply because it has a low computation burden and does not require information about meteorological conditions or emissions inventories.

CMB calculations have been carried out in numerous studies around the world. Limitations of CMB include the need for a relatively high amount of detail in data used in the analysis (including, for instance, measurements of a broad spectrum of hydrocarbon species). In order to differentiate sources, CMB modeling also requires that the sources have identifiable differences in speciation profiles. It is difficult, for instance, to ascertain through CMB modeling if impacts come from a particular region.

Source-based models use spatially and temporally variable emission rate information—combined with modeling of atmospheric transport, chemical transformations, and deposition processes—to determine the concentration and deposition of pollutant in a study domain. Source-based approaches require significantly more input data and modeling resources in comparison to receptor-based models. Examples of source-based models are Gaussian models, such as the CALINE series of roadway transport models and the EPA’s ISCST3 and AERMOD models (AERMOD is being phased in to replace the ISCST3 model), and Eulerian grid models, such as EPA’s Community Multiscale Air Quality modeling system (CMAQ).

One goal of this study is to determine the amount of nitrogen deposition that comes from new and existing transportation sources within the study area as compared to sources further upwind, outside the study area. Because the pollution profile of nearby and distant roadway emissions will likely be indistinguishable from a CMB modeling perspective, it is unlikely that a receptor-based methodology can determine the exact source of nitrogen transport to serpentine grasslands. Consequently, a source-based model was used for nitrogen source apportionment to the serpentine grasslands in the study area.

When adequate input data are available, the CMAQ model is likely to provide the most accurate characterization of atmospheric transport in the region because it allows for non-uniform atmospheric conditions and multiphase chemical transformations. However, complex models such as the CMAQ model require extensive data that are sometimes difficult to prepare. Improper preparation of data can result in the simulation being overly sensitive to initial and boundary conditions or other modeling complications. For instance, if winds are not accurately represented in the CMAQ input fields, inaccurate transport and deposition fields could be simulated. Furthermore, depending on the location of the domain boundaries and the size of the modeling domain, boundary conditions can dominate study results, making it difficult to interpret the simulated nitrogen deposition patterns. For a study such as this one, it is desirable to have existing meteorological and emissions databases available in order to avoid having to invest in developing and evaluating these data.

Gaussian models such as the CALINE series of models and ISC and AERMOD are much simpler than the CMAQ model. However, these models do not account for the complex chemical transformations and transport processes in the atmosphere. Gaussian models perform best when the meteorological site used to supply input data for the model is in close proximity to the sources and receptors of interest. Unfortunately, routinely available meteorological data are not always

ideally located for all studies. In this study, the sites used to supply meteorological data were located up to 50 kilometers (km) from the sources and receptor areas considered. Although not ideal, this relative spacing between meteorological sites and study area is typical of most studies using Gaussian models.

The spatial scale appropriate for application of the Gaussian models versus that for the Eulerian models is quite different. The formulations of Gaussian models are valid up to a few km from the sources simulated. The formulation used in Eulerian models was developed for horizontal grid spacing ranging from a couple of kilometers up to much larger spacing. Practically speaking, developed databases for Eulerian models with resolution finer than about 4 km are rarely available.

The modeling techniques considered for this study share the following in their methodology. Air concentrations of nitrogen species are calculated by the models. Deposition is calculated using a deposition velocity expressed in units of meters per second (m/second), such that the deposited mass can be calculated using the following equation:

$$D = C * V_d * t$$

where  $D$  is the deposited mass in  $\mu\text{g}/\text{m}^2$ ,  $C$  is concentration in  $\mu\text{g}/\text{m}^3$ ,  $V_d$  is deposition velocity in m/second,  $t$  is the time interval considered in seconds. The units employed for the various quantities in this equation may vary among the models (and therefore could require the inclusion of conversion factors), but this basic calculation is made in the case of all the models considered here.

## Air Quality Modeling Approaches Employed in this Study

For this study, ICF analyzed nitrogen deposition using several modeling approaches. One of the principal goals of the project is to estimate the sources that contribute to deposition in the habitat areas. In order to estimate contributions from individual roadways and to assess the increase in deposition due to increases in traffic, Gaussian models for a limited domain were applied around the habitats. The much more complex CMAQ model was also used to simulate the area's more complex nitrogen transport processes, and, using the PPTM source apportionment technique, to estimate contributors to deposition on a broader scale. Meteorological data for the Gaussian models are readily available. Gaussian models are commonly used to characterize overall air quality transport trends, but because they are very simplified, results from Gaussian models are best taken in context with more comprehensive modeling techniques such as the CMAQ model. For instance, a Gaussian model requires that the wind field is uniform speed at all elevations and across the entire area of interest.

In this application, meteorological data for several recent years were used in the Gaussian model simulations. On the other hand, treating all of the various area,

mobile, and point source emissions (regional and local), is difficult in the Gaussian models. Gaussian models were used to investigate the impacts of local roadways on the habitat areas, but characterizing the overall deposition was not attempted with these models given the simplicity of the models and their inability to capture certain transport and fate processes.

Due to the development time required to prepare the various meteorological and emissions inputs required for CMAQ modeling, we were constrained in this project to use existing modeling databases for CMAQ. Therefore existing CMAQ modeling databases from the California Air Resources Board (CARB) and the Bay Area Air Quality Management District (BAAQMD) were used as the starting point for modeling. The modeling databases available used a 4-km-square grid resolution for the modeling region and are populated with data from a winter episode period. Annual simulations available from CARB use 12-km resolution, which is not adequate to resolve the areas of interest around the target habitats. The areas of interest in this study are the serpentine bunchgrass grasslands shown in Figure E-8.

## Background on Future Emissions Estimates

Emissions for the base year Gaussian modeling were based on traffic counts for highways and roads in 2005, as described below in more detail. For CMAQ modeling, base year emissions were acquired from BAAQMD. At the time the modeling was conducted, however, no future year emissions projections were available. In the sections below, we include extrapolations of emissions to future years based on projected growth in the Bay Area. Over the time period for which emissions projections are now (as of 2011) available, NO<sub>x</sub> emissions are expected to decrease in the Bay Area. NO<sub>x</sub> emissions in the Bay Area, dominated by on-road mobile emissions in 1990, are expected to be dominated by non-road mobile sources by 2025 (Bay Area Air Quality Management District 2011). Given the current trends, further reductions in NO<sub>x</sub> emissions from turnover in the on-road mobile fleet will be smaller than in the past since NO<sub>x</sub> emissions from this sector will already be small by 2025. Note that from 2022 to 2025, Bay Area NO<sub>x</sub> emissions are projected to increase slightly over 2021 levels (Bay Area Air Quality Management District 2011).

Looking beyond the available projections to the years 2030 and 2060, emissions in the Bay Area would not be expected to continue to increase. Some additional benefit will be seen from fleet turnover, and additional regulation will likely curb growth in other areas. However, in order to assess the potential for impact on the habitat should emissions continue to grow, we have included deposition estimates in the sections below based on extrapolation of emissions. In all likelihood, these deposition estimates overestimate impacts, but show that increases in NO<sub>x</sub> emissions lead to roughly proportional increases in deposition to habitat areas.

## Gaussian Modeling

Gaussian modeling provides relatively high spatial resolution modeling that can estimate impacts from individual roadways or point sources. In contrast with Eulerian grid models such as CMAQ (see following section), which resolve spatial features down to about a 4-km scale, Gaussian models are applicable within a few km of the simulated sources and can differentiate receptors located only a few meters apart. For this study, Gaussian modeling was used to simulate the deposition from some major roadways that are located near the target habitat and to estimate future increases in deposition from these roadways.

Because of its limited spatial range, Gaussian modeling is not well suited to characterizing the effects of sources outside of the limited area considered in this study. Hence, observations of  $\text{NO}_x$  concentrations were used to estimate the overall amount of ambient  $\text{NO}_x$  and the overall contribution to deposition. Vehicular sources of  $\text{NH}_3$  were not considered in the Gaussian modeling but will be discussed later.

In this section the sources of data used as input to the Gaussian modeling are described, chemical conversion processes affecting the deposition of nitrogen emissions are discussed, the specifics of the setup for the Gaussian modeling are described, and estimates of nitrogen deposition based on the Gaussian modeling are provided.

## Meteorological Data

Gaussian modeling requires meteorological data to specify local temperature, wind speed, wind direction, and relative humidity. Upper air sounding data are also needed to characterize atmospheric mixing. For this application, surface meteorological data were acquired from the National Climatic Data Center (NCDC) for the surface site at the San José Airport. The upper air data were acquired from NCDC for the Oakland sounding. Both sets of data were acquired for the years 2005, 2006, and 2007.

Data were prepared for input to CAL3QHCR using the RAMMET preprocessor. For AERMOD simulations, the data were prepared using the AERMET processor.

## Atmospheric Chemistry of Nitrogen

A complete treatment of nitrogen deposition must include all the various compounds in which nitrogen appears in the atmosphere. These compounds are treated in detail in models such as CMAQ, but Gaussian models treat only the directly emitted compound, perhaps including a single transformation or decay reaction. In order to support our discussion below of compounds to be considered in the Gaussian modeling, we present a highly abbreviated discussion of the

atmospheric chemistry of nitrogen. For further detail, the reader can refer to any of a number of available textbooks treating the atmospheric chemistry of smog formation.

Compounds of concern emitted from anthropogenic sources, either mobile or stationary, are primarily NO and NO<sub>2</sub>, collectively referred to as NO<sub>x</sub>. The composition of NO<sub>x</sub> emissions is generally 90%–95% NO, with the remainder being NO<sub>2</sub>. Chemical processes in the atmosphere, particularly the reaction of NO with ozone, rapidly convert the NO to NO<sub>2</sub>. The effects of atmospheric chemistry do not end here, however, as the action of hydrocarbons and short-lived species called radicals continue to convert the NO<sub>2</sub> to a variety of additional compounds that have very different properties from the original NO<sub>x</sub> emissions.

Among others, these compounds include nitrous acid (HONO), nitric acid (HNO<sub>3</sub>), peroxyacetyl nitrate (PAN), and organic nitrates. Nitric acid will further react with NH<sub>3</sub> in the atmosphere to form ammonium nitrate (NH<sub>4</sub>-NO<sub>3</sub>). When examining the fate of emitted nitrogen (as we are in estimating nitrogen deposition), we must also consider the fate of these derivative compounds. After some hours or days of the action of atmospheric chemistry, what remains of the emitted NO<sub>x</sub> will be primarily in the form of NO<sub>2</sub>. A significant amount of nitrogen mass may also appear in the form of the derivative compounds above. The discussions below consider ways in which we might be able to augment the Gaussian modeling of NO<sub>2</sub> to include the effects of these other compounds on nitrogen deposition.

## Background Levels of NO<sub>x</sub>

In order to estimate the fraction of deposition due to a particular source, some estimate of the overall concentrations (and, hence, deposition) is necessary. Because the Gaussian modeling is not well suited to estimating the overall concentrations, we look to monitoring data to make this estimate. The EPA archives data from monitors around the country in order to assess trends in pollutant concentrations. Hence, we refer to these as “trends monitors.” Trends monitors in San José show ambient NO<sub>x</sub> at around 20 parts per billion (ppb) over the past several years, so this value was used as the background NO<sub>x</sub> concentration. Because this is an aged air mass, it was assumed this is primarily NO<sub>2</sub>. In addition to NO<sub>2</sub>, there will also be some other nitrogen compounds present in the atmosphere. Monitoring of the makeup of nitrogen compounds in the atmosphere has been undertaken for several sites in southern California (Buhr et al. 2005). At the more urban sites reported in the Buhr study (Fresno and Bakersfield), the nitrogen appears mostly as NO<sub>x</sub> (nitrogen oxide [NO] and NO<sub>2</sub>). Contribution from PAN is quite small. The contribution from nitrate is not insignificant, however. For the Fresno site, nitrate accounts for about 10% of the nitrogen. At Bakersfield, the nitrate is a little higher at about 20% of the total nitrogen.

In order to make estimates of overall nitrogen deposition (independent of the Gaussian modeling), a concentration of 20 ppb of NO<sub>2</sub> was used and a factor of

0.15 times the  $\text{NO}_2$  was used as nitrate concentration. (See <http://www.arb.ca.gov/adam/> and <http://www.epa.gov/airtrends/nitrogen.html>, data for San José Jackson Street site, 2005.) These figures are based on a review of monitoring data in the South Bay. Nitrate derives from nitric acid, and for ambient air (an aged air mass), it was assumed the nitric acid would all appear as particulate nitrate.

## Conversion of $\text{NO}_x$ to Nitric Acid

The primary focus of this study is deposition of nitrogen. Although most emissions are initially introduced into the atmosphere as  $\text{NO}$  and  $\text{NO}_2$ , chemical processes in the atmosphere rapidly convert these emissions to other forms. Nitric acid is of particular concern among these conversion products because it deposits much more rapidly than the emitted species. Gaussian models do not treat the products of atmospheric chemistry, so in this section we consider how much of the emitted  $\text{NO}_x$  might be converted to nitric acid and how that might affect the Gaussian model estimates of nitrogen deposition.

Treating the emissions as inert  $\text{NO}_2$  would likely underestimate the near source deposition because the deposition velocity for the emitted species is low. Therefore, the amount of emitted  $\text{NO}_x$  converted to nitric acid was estimated using box model simulations. Box model simulations treat an individual parcel of air, calculating chemical transformations and diurnal variations in temperature and solar radiation. Mixing with surrounding air is not included, and, for our purposes, emissions are limited to the initiation of the simulations. These box model simulations made it possible to make an alternate calculation of nitrogen deposition assuming that some fraction of the emissions were converted to nitric acid.

Box model runs were made with the Ozone Isopleth Plotting Package (Revised) OZIPR model (Gery and Crouse), using the SAPRC97 chemical mechanism. The model was configured as a box model by maintaining a constant mixing height throughout the simulation. No deposition was simulated. The location, which allows the model to calculate the solar radiation intensity, was set to the latitude and longitude of San José.

Four different sets of meteorological conditions were used representing the four seasons: winter—January 15, 2005; spring—April 15, 2005; summer—July 15, 2005; fall—October 15, 2005. The meteorological differences include the ambient temperature, relative humidity, and amount of solar radiation (calculated by OZIPR based on the location and the date). (Since these OZIPR simulations are used only to obtain a rough estimate of the conversion rate to nitric acid, an exhaustive characterization of meteorology was not made for the OZIPR simulations. Although the data for temperature and humidity collected from these dates is not necessarily typical of the entire season in which they were collected, the solar radiation calculated for these mid-season dates is representative of the unattenuated seasonal values. This limitation on the detail in the meteorology does not apply to the Gaussian model simulations discussed later which used

hourly meteorology. More complete treatment of chemical effects is included in the CMAQ model simulations that are discussed later in this report.)

As expected, the rate at which  $\text{NO}_x$  is converted to nitric acid is strongly dependent on the amount of hydrocarbon and  $\text{NO}_x$  in the system. The choice of ambient levels of hydrocarbon and  $\text{NO}_x$  is therefore very important. The emissions from an individual source cannot be considered without regard to background because the rate of conversion is determined by the overall hydrocarbon and  $\text{NO}_x$  in the atmosphere near the source.

Based on annual average NMHC concentrations at the San José central monitor operated by BAAQMD (the only monitor available in the area) for the years available (2006 onward) and adjusted downward to account for non-reactive fraction, initial volatile organic compound levels for this study were set to 80 parts per billion of carbon. Trends monitors in San José show ambient  $\text{NO}_x$  at around 20 ppb over the past several years, so this was selected as the initial  $\text{NO}_x$ .

Figures E-1 through E-4 below show the fraction of the initial  $\text{NO}_x$  converted to  $\text{HNO}_3$  as a function of distance from the starting point. Each of the lines on each chart represents a different hour of the day, and each line is identified by the time in 2400 hour military time (e.g., 800, 8 AM; 1400, 2 PM). ( $\text{NO}_x$  is also converted to other species such as PAN and HONO (nitrous acid), but these are relatively small contributors to total mass of nitrogen.) The percent  $\text{HNO}_3$  is expressed as a function of distance from the source by using a wind speed of 3.7 km/hour. The lowest wind speed (other than calm) reported in each of the three years (2005, 2006, and 2007) of met data used in the Gaussian modeling is 3.6 km/hour. A wind speed of 3.7 km/hour is therefore a small but reasonable value of the wind speed. The choice of this wind speed in one sense make this a “worst case” analysis because the low wind speed allows more of the  $\text{NO}_x$  to be converted to nitric acid within the range of the habitat area. Lower wind speeds are, of course, possible though and are reported in our data files as calm. The choice of a wind speed for this calculation that is lower than the smallest value in the data would be difficult to justify, though, since it cannot be verified based on routinely available observations.

The figures extend to 8 km because the largest segment of Bay checkerspot butterfly habitat is roughly in the range of 0 to 8 km from US 101 and this range roughly matches the domain used in the Gaussian modeling. Using a higher wind speed would result in less conversion to nitric acid within this distance while a lower wind speed (e.g., calm conditions) would result in greater conversion in this range.

Simulations were started at several different times of day, as indicated on the legend for the charts. Midday start times in summer result in almost 25% of the initial  $\text{NO}_x$  being converted to nitric acid within 8 km of the source. There is a strong seasonal variation, the result of reduced solar radiation and lower temperatures in the winter.

In addition to the results in the displays, simulations were also run at several different initial  $\text{NO}_x$  levels. For comparable conditions, the percentage of  $\text{NO}_x$  that was converted to  $\text{HNO}_3$  ranged from over 30% for an initial  $\text{NO}_x$  of 5 ppb to only about 7% for an initial  $\text{NO}_x$  of 60 ppb. Hence, there is a great deal of uncertainty regarding how much  $\text{NO}_x$  would be converted to nitric acid at any distance from a source.

Given the amount of  $\text{NO}_x$  that might be converted to nitric acid within a relatively short distance from the source, it is important to make some attempt to estimate how much deposition might be enhanced by considering the nitric acid concentrations. Considering the amount of uncertainty in these estimates and the need to keep the treatment simple for compatibility with the Gaussian model output, there will be uncertainties inherent in any treatment selected. Estimated nitric acid for daylight hours was based on a linear function of distance from the source. In each of the charts, the line for 1400 hours represents a roughly middle-of-the-road case, representing neither the highest percentage of nitric acid nor the lowest percentage of nitric acid. For each season, therefore, the linear function that was used to calculate the fraction of nitric acid was the percent conversion curve for 1400 hours.

## Modeling Using the CAL3QHCR Gaussian Model

The modeling domain used for the CAL3QHCR modeling was centered on 37.19N/121.69W and extended 15 km in each direction from that point. This domain extends from southern San José to northern Gilroy and includes several of the habitat areas (See Figure E-5 where habitat areas are shown as colored outlines on the map). Many roadways are located in proximity to the habitat units, the most important of these being US 101, State Route (SR) 85, Monterey Highway/Route 82, Santa Teresa Boulevard, and Hale Avenue. Simulations of Santa Teresa Blvd. and Hale Avenue were combined, so references to Santa Teresa Blvd. include the combined effects of Santa Teresa Blvd. in the north and Hale Avenue in the south. Simulations were run with CAL3QHCR for each of these roadways separately in order to assess their deposition impact separately, and deposition estimates for the base year (2005), 2035, and 2060 were made. Deposition estimates for an assumed overall average  $\text{NO}_2$  air concentration of 20 ppb were also made based on a review of trends monitors in the San José area. (See <<http://www.epa.gov/airtrends/nitrogen.html>>.)

**Figure E-5. Modeling Domain Included in the Gaussian Model Simulations**

The highways listed above were broken up into segments for the purpose of modeling with CAL3QHC. The intersections defining the intervals on the

highways are shown in Table E-1. Traffic volume between each of the intervals defined by these intersections were acquired from the San José Department of Transportation (Ma pers. comm.) and from summaries of traffic volumes from the California Department of Transportation (State of California 2006). Traffic counts for a base year (2005) and for a projected future year (2030) are provided. Recognizing this may be an overly simplistic methodology, projected traffic counts to 2060 based on the ratio of traffic counts in 2030 to traffic counts in 2005 are also provided. Average traffic counts for each roadway are presented in Table E-2. Note that the traffic counts in Table E-2 implicitly include contributions from projects that have or may have already taken action to accomplish N-deposition mitigation. Our analysis included these trips because we did not have access to data that excluded these projects, nor would it be feasible to exclude those projects consistently. The model results that use these traffic counts do not alter the assumptions used in the fee analysis, but rather provide justification for imposing the fee.

Variation of traffic counts (and hence emissions) during the day was imposed by applying a diurnal profile which varied by hour. The profile was derived from mobile emissions profiles used in the Sparse Matrix Operator Kernel Emissions (SMOKE) Modeling System<sup>4</sup>. The profile is presented in Figure E-6.

**Figure E-6. Diurnal Variation in Traffic Counts (Normalized to Sum to 1)**

Based on EMFAC2007 simulations, an average emissions rate of 0.915 g/veh-mile of NO<sub>x</sub> emissions was used in order to estimate emissions for the major highway segments (US 101 and SR 85). This rate is based on the assumption of a

<sup>4</sup> SMOKE is a standard processing package used for preparation of emissions for CMAQ and other Eulerian grid models. For more information, see [www.cmascenter.org](http://www.cmascenter.org).

60 mph average speed, a temperature of 70 F and 50% humidity. An average speed of 60 mph is reasonable for this type of road. Note that emissions are not a strong function of speed (see Figure E-7). Temperature and humidity choices represent neither of the extremes of either range and give emissions estimates in roughly the middle of the range predicted by the EMFAC model. The most extreme choices for these parameters could result in only a 50% increase or decrease in emissions. For the Monterey Highway and Santa Teresa Blvd. segments, a lower average speed of 45 mph was used giving an emissions rate of 0.777 gram/vehicle-mile. For reference, the variation of emissions as a function of speed is shown in Figure E-7. Note that the available speed curve does not go above 65 mph. Travel speeds on US 101 and SR 85 could exceed this speed at times which might affect the emissions estimates.

Twenty-one receptors were placed around the domain. Some of these were included to allow a general spatial distribution to be inferred. Others were specifically located in order to characterize effects on the habitat areas (habitat units) of the Bay checkerspot butterfly. Receptors were located in each of the disjoint habitat areas. Several of the receptors are located along the important Coyote Ridge, as noted in Table E-3. The receptors that are directly associated with a habitat area are shown in Table E-3 with the habitat unit that the receptor represents.

**Figure E-8.** Receptor Locations (Deposition estimates are presented in Figures E-10 through E-24)

The CAL3QHCR code was modified to write hourly concentration estimates and meteorological data to an output file. Deposition velocities were then applied to the simulated concentrations in order to calculate deposition mass at each hour for each of the simulated years. The deposition velocities were derived from the AERMOD deposition algorithm using a diagnostic option available in the model. The deposition velocities vary in time and range from about 0.02 cm/s to 0.4 cm/s, with an average of about 0.2 cm/s. Surface characteristics were developed by the AERSURFACE preprocessor using a center location consistent with the center of the domain used for the Gaussian modeling. The CAL3QHCR model does not calculate deposition. Deposition was calculated after the fact by applying a deposition velocity to the concentrations predicted by CAL3QHCR. Had the model included the deposition calculation internally, the predicted concentration would have been lower due to the effects of deposition. Therefore, the external calculation of the deposition velocities overestimates the amount of deposition. Note that we have not considered ammonia deposition in the Gaussian modeling. Ammonia deposition could add measurably to the total nitrogen deposition because it deposits more readily than NO<sub>2</sub>.

On page 10, we used monitoring data to estimate total ambient NO<sub>2</sub> concentrations to be about 20 ppb. Nitrate concentrations were estimated to be about 0.15 times the NO<sub>2</sub> concentrations. We can make an estimate of the overall nitrogen deposition from all sources by applying the deposition velocities calculated by AERMOD to these ambient NO<sub>2</sub> and nitrate concentrations. The application of the deposition velocities to the 20 ppb estimate of ambient NO<sub>2</sub> results in the total annual deposition listed in Table E-4 for each of the three meteorological years considered. The second line assumes additional deposition due to contribution from nitrates containing 0.15 times the mass of nitrogen in the ambient NO<sub>2</sub>. Appropriate particulate deposition velocities, again derived from AERMOD, were used for estimating the deposition of nitrates. The estimates for nitrates combined with NO<sub>2</sub> give overall deposition in the range of 5.9 to 6.4 kg-N/hectare [ha]/year. This overall estimate of deposition will be useful for comparison to the individual link estimates to be presented later. Based on figures presented by Tonnesen et al. (2007) (See Figure E-9) which showed total nitrogen deposition between 8 to 11 kg-N/ha/year, this overall estimate of deposition is consistent with their modeling based estimates.

**Figure E-9.** Nitrogen Deposition Simulated at 4-km Resolution using the CMAQ as Presented by Tonnesen et al. (2007)

**Table E-4.** Estimated Deposition (kg-N/ha/yr) from Ambient NO<sub>2</sub>

Year	2005	2006	2007
Deposition from NO <sub>2</sub>	4.5	4.8	4.9
Deposition from nitrate	1.4	1.5	1.5
<b>Estimated total</b>	<b>5.9</b>	<b>6.3</b>	<b>6.4</b>

Deposition estimates were made for each receptor (for each of the roadways noted above) and for each of the three meteorological years. The resulting annual total deposition estimates for each receptor for 2005 emissions averaged over the three meteorological years are shown in Figure E-10 and in Table E-5. These estimates use only deposition of NO<sub>2</sub> (i.e., no conversion to nitric acid is considered). At most sites, the simulated deposition from US 101 is higher than the simulated deposition from any other the other roadway links that were simulated. There are some comparable contributions from SR 85 for some of the more northerly receptor locations (e.g., Santa Teresa North). The magnitude of the simulated deposition is less than 0.1 kg-N/ha/y for any single roadway link at any of the receptors. This is only a small fraction of the approximately 6 kg-N/ha/y estimated above based on ambient NO<sub>2</sub> levels. The impact of roadways located some distance from US 101, even though comparable in traffic load such as SR 85, is low compared to US 101. This implies that the traffic on additional roadways not simulated here would not increase the simulated deposition to a level comparable to the ambient calculation. The lower deposition simulated in the CAL3QHCR runs warrants some discussion.

We have alluded to, but not explicitly stated, some potential reasons for lower deposition in the Gaussian model simulations. The Gaussian model simulations consider sources from only a limited area surrounding the habitats. That area includes only a small part of San José and part of Santa Clara County and does not include the remainder of the Bay Area or the rest of the state. We expect (and this expectation is corroborated by the CMAQ tagging simulations presented later) that sources outside of this limited area will also contribute to nitrogen deposition in the habitat area. Only selected, heavily traveled roadways are considered in our simulations. Other roadways not simulated here will contribute to nitrogen deposition, although we expect to a lesser extent than the roadways we are simulating. Chemical transformations may enhance nitrogen deposition. We attempt to account for the chemical effects by assuming some conversion to nitric acid, but it is possible that our necessarily simple approach may still underestimate the effects of these chemical transformations. (The effect of including nitric acid is presented next.)

We must therefore accept that the Gaussian model simulations cannot give an estimate of overall nitrogen deposition. Nevertheless, the comparison of the Gaussian model simulations for different sites and roadway links can give us an indication of which roadways could have the greatest impact on particular habitat areas.

The total annual deposition differs somewhat depending on which of the three meteorological years is considered. The variation among the meteorological years can be expressed as the maximum percent difference among the results for all receptors. The variation in simulated deposition depending on the meteorological year is largest for the simulation of Santa Teresa Blvd and smallest for the US 101 simulation. The range of variation in deposition due to choice of meteorological year depending on receptor is summarized in Table E-6 for the 2005 emissions. The large variation for Santa Teresa Blvd. is most likely due to differences in prevailing wind direction resulting in very low impacts in some areas for some years but more significant impacts in others.

**Table E-6.** Minimum and Maximum Variation among Meteorological Years for the Roadways Simulated Using the CAL3QHCR Model

Santa Teresa Blvd.	0.004	2	1245

Earlier in this report, it was noted that chemical effects, in particular conversion of NO<sub>2</sub> to nitric acid, could enhance deposition of nitrogen. Using the methodology described in the earlier section, deposition was calculated assuming some conversion of NO<sub>2</sub> to nitric acid. Deposition velocities for nitric acid were

derived from AERMOD. The estimates of deposition of nitrogen, including the effects of conversion to nitric acid, are presented in Figure E-11 and Table E-7. The estimates of nitrogen deposition increase by more than a factor of 2 when the effects of nitric acid are included. The maximum simulated deposition from US 101 emissions is slightly more than 0.2 kg-N/ha/y.

When the emissions are extrapolated to 2030 reflecting projected increases in traffic volume, estimated deposition increases at all receptors (see Figure E-12 and Table E-8). Note that the relative increase is larger for the (currently) less-traveled roadways than for US 101. In particular, note that when nitric acid is included, the increase in deposition due to Santa Teresa Boulevard is considerable (see Figure E-13 and Table E-9). Traffic volumes are projected to increase several times between 2005 and 2030 on Santa Teresa Blvd. (a larger percent increase than any of the other simulated roadways), so the increase in deposition is consistent with the increased traffic.

Using the extrapolation of emissions to 2060 shows even greater increases in the deposition estimates. Impacts from US 101 alone reach levels greater than 0.2 kg-N/ha/y (see Figure E-14, and note change in scale for 2060, and see Table E-10). Including nitric acid further increases the estimated deposition (see Figure E-15 and Table E-11). Impacts from US 101 are for some receptors three times the 2005 levels. The extremely large increase in impact from Santa Teresa Boulevard may be an overestimate. Because these emissions were extrapolated, the rate of increase between 2005 and 2030 might not be maintained until 2060.

In order to provide a sense of the development of deposition over time, Figures E-16a–d presents stacked bar charts showing all three emissions years and the contributions from the simulated roadways for several habitat areas: Hale Avenue, Silver Creek Hills Central, Santa Teresa Main, and Pound Site. Pound Site and Silver Creek Hills Central, which are located along the Coyote Ridge area east of Highway 101, receive the largest increase in deposition from Highway 101. These sites also see increases in the contribution from other roadways in the area. Sites like Santa Teresa Main which originally saw contributions from several roadways, see increases in all these contributions. The Hale Avenue site sees a dramatic increase in deposition, coming primarily from the Santa Teresa Blvd. simulation. (Recall that the Santa Teresa Blvd. simulation included both Santa Teresa Blvd. and Hale Avenue.) This increase in deposition is due to the relatively larger projected percentage increase in traffic volume on roadways in the southern part of the modeling domain. On all roadways, increases in deposition using emissions extrapolated to 2060 are several times current deposition levels. Keep in mind, however, that the 2060 emissions are extrapolated from projected increases in 2030 and could be overestimated.

## Modeling with the AERMOD Gaussian Model

AERMOD simulations were conducted over the same area and for the same meteorological and emissions years as the CAL3QHCR simulations. The emissions for AERMOD were prepared as area sources, using the length of each highway segment as one dimension of each area and an estimated width of the roadway for the width of each segment. Total emissions for each of the roadways within the simulated area is shown in Table E-12.

**Table E-12.** Total Emissions Simulated as Area Sources AERMOD for Each Roadway

Roadway	Total daily emissions (tpd)		
	2005	2030	2060
US 101	2.71	4.26	8.06
Route 85	0.43	0.69	1.32
Monterey Highway	0.31	0.77	2.27
Santa Teresa Blvd.	0.07	0.78	9.73

The AERMOD simulation included gaseous dry deposition of NO<sub>2</sub>. In addition, as a post-processing step, we calculated the enhanced deposition due to inclusion of conversion to nitric acid. The same methodology was used to estimate the conversion as was used for the CAL3QHCR simulations.

The variation among meteorological years (see Table E-13) is similar for AERMOD to CAL3QHCR for Highway 101 and for Route 85. Maximum variation for Monterey Highway and Santa Teresa Blvd. is smaller using AERMOD than using CAL3QHCR.

**Table E-13.** Minimum and Maximum Variation of Simulated Nitrogen Deposition among Meteorological Years for the AERMOD Simulations

Roadway	Mean Deposition (Averaged over all receptors) (kg/ha/y)	Minimum Variation (%)	Maximum Variation (%)
Highway 101	0.088	4	26
Route 85	0.018	14	96
Monterey Highway	0.012	9	28
Santa Teresa Blvd.	0.004	6	75

The deposition simulated by AERMOD is presented in Figure E-17 and Table E-14 for the 2005 emissions and the average of the three meteorological years. In most cases, the AERMOD simulations produce higher deposition estimates than the CAL3QHCR simulations did. The differences between the two models range from a few percent to over 100% using base emissions and including only NO<sub>2</sub> deposition. The percent differences are smaller when deposition from nitric acid is included. The percent difference between the two models using 2005 emissions levels, with and without nitric acid deposition, is shown in Figure E-17. The maximum deposition estimates for 2005 using AERMOD are about 0.15 kg-N/ha/y.

**Figure E-18.** Percent Differences in Simulated Annual Nitrogen Deposition between the AERMOD Simulation and the CAL3QHCR Simulation with 2005 Emissions Levels Averaged over Three Meteorological Years (2005, 2006, 2007) due to Deposition of NO<sub>2</sub> and due to Deposition of NO<sub>2</sub> and Nitric Acid

Including the effects of nitric acid conversion increases the estimated dry deposition of nitrogen in the AERMOD simulation results (See Figure E-19 and Table E-15). Estimated deposition is increased at each roadway and each receptor. Deposition estimates from AERMOD show somewhat more similarity to the CAL3QHCR than when only NO<sub>2</sub> deposition is considered. The maximum simulated deposition at any receptor is greater than 0.2 kg-N/ha/y.

The simulated deposition for 2030 using AERMOD are again higher at many sites than using CAL3QHCR for Highway 101 (see Figure E-20 and Table E-16). A few sites, however, have higher simulated values using CAL3QHCR than using AERMOD for the smaller roadways. Including nitric acid deposition increases the deposition estimates from AERMOD (see Figure E-21 and Table E-17). With only a few exceptions, the simulated values from the two models are more similar when nitric acid deposition is included. The maximum simulated deposition using AERMOD with 2030 emissions and including nitric acid is greater than 0.35 kg-N/ha/y.

The simulations using emissions extrapolated to 2060 result in the greatest increases for Santa Teresa Blvd. Maximum simulated deposition due to Santa Teresa Blvd. using AERMOD with these emissions is greater than 1.0 kg-N/ha/y (see Figure E-22 and Table E-18). (Please note the change in scale for the 2060 plots.) When deposition of nitric acid is included, the simulated deposition using AERMOD is considerably higher for Santa Teresa Blvd. than the CAL3QHCR simulations, reaching a maximum of more than 1.9 kg-N/ha/y (see Figure E-23 and Table E-19). The CAL3QHCR simulation results are higher for the next most important roadway in 2060, Highway 101. The reader is once again cautioned that the extrapolation of the emissions to 2060 may not be valid.

Summaries of the overall deposition simulated in the AERMOD simulations for the Hale Avenue, Silver Creek Hills Central, Santa Teresa Main, and Pound Site habitat areas are shown in Figures E-24a–d. Overall deposition is in general slightly higher than the simulated values from the CAL3QHCR simulations. There is, however, a larger increase in the AERMOD simulations due to the increase in traffic in the southern part of the domain than was predicted by the CAL3QHCR simulations. In the AERMOD simulations, the contributions to deposition at the Hale Avenue site from the simulated roadways are estimated to increase by a factor of more than 10 using the extrapolated 2060 emissions relative to the base year emissions.

## Summary of Gaussian Modeling Results

Two Gaussian models were applied: CAL3QHCR and AERMOD. Nitrogen deposition was calculated from the CAL3QHCR results using deposition velocities derived from AERMOD. AERMOD simulations included dry deposition. For both models, an additional calculation was made to estimate the effects of nitric acid formation on nitrogen deposition. The two Gaussian models produce deposition estimates that are of the same order of magnitude. Maximum deposition from Highway 101 is estimated to be on the order of 0.1 kg-N/ha/y to 0.2 kg-N/ha/y using 2005 emissions. Using emissions extrapolated to the future, estimated deposition is projected to increase considerably, particularly for the currently less traveled roadways. Nitrogen deposition estimates larger than 0.5 kg-N/ha/y were simulated for several roadway receptor combinations using future-year emissions. Ammonia deposition was not simulated using the Gaussian models. Given the nature of Gaussian models, the ammonia deposition will be (to the first order) a linear multiplier of the  $\text{NO}_2$  results. However, the higher deposition velocity of  $\text{NH}_3$  may lead to sharp roadside gradients. Areas close to US 101 in particular may be subject to larger deposition due to the effects of ammonia.  $\text{NO}_x$  deposition for the Coyote Ridge area may be inferred from the results for Pound Site and for Kirby Landfill. Note that these results include only the mobile source contribution from the highways modeled and do not represent overall deposition. Note also that these estimates include only deposition resulting from  $\text{NO}_x$  emissions and do not include ammonia deposition.

For particular roadways and emissions years, one or the other model may produce higher estimated deposition, but both models produce estimates substantially lower than the estimate from the ambient calculation and the CMAQ modeling estimates in the following section (on the order of 6 kg-N/ha/y).

## CMAQ Modeling

This section describes the application of the CMAQ model to simulate nitrogen deposition in the study area. The CMAQ model is an EPA recommended model for regulatory air applications and includes state-of-the-science algorithms for transport, chemistry, deposition, particulate formation, and other atmospheric processes. CMAQ is a data intensive modeling system that requires vastly greater resources to run than the Gaussian models used in the previous sections. Application of CMAQ requires considerable specialized expertise.

## Source Apportionment Methodology

ICF has recently enhanced the CMAQ model to include source attribution capabilities for ozone and particulate matter with the implementation of the Oxidant and Precursor Tagging Methodology (OPTM) and the PPTM. The tagging methods are designed to provide detailed, quantitative information about the *contribution* of selected sources, source categories, and/or source regions to simulated ozone and particulate matter 2.5 microns in diameter or less (PM<sub>2.5</sub>) concentrations, respectively. Emissions of precursor pollutants from selected sources, source categories, or source regions are numerically tagged (i.e., labeled) and then independently tracked throughout a simulation. The contribution from each tag to the resulting simulated concentration of ozone, PM<sub>2.5</sub>, or any of the PM<sub>2.5</sub> component species for any given location within the CMAQ modeling domain can be quantified. By tracking the emissions from selected sources or source locations, the methodology also provides information on the fate of the emissions from these sources, including the contribution of each tagged source to deposition.

The tagging methodology differs from the use of air quality model sensitivity simulations in which the emissions are modified or eliminated (zeroed-out). Sensitivity simulations typically provide information about the effects of changes in the emissions on the simulation results. In contrast, tagging provides information about the contribution of the emissions from the tagged sources, relative to the unmodified simulated conditions. Identifying and quantifying source contributions from certain sources or source sectors can inform air quality planning and aid the identification of effective control strategies.

Applying CMAQ with PPTM provides the same estimate as a standard PPTM run for the overall concentration of each species, but in addition the amount of nitrogen originating from each tagged emissions source or category can be derived from the model outputs. For instance, the amount of nitrogen associated with motor vehicle emissions could be ascertained by setting up a tag of mobile source emissions.

PPTM is implemented in CMAQ with a level of detail consistent with the model. PPTM tracks individual species, taking into account different particle size modes and tracking changes at the process and subprocess level. For example, PPTM

has a separate tracer (or tag) for each nitrogen species (e.g., NO, NO<sub>2</sub>, NO<sub>3</sub>, N<sub>2</sub>O<sub>5</sub>) and each is advected as a separate species using the model algorithms. For sulfate, PPTM tracks each specific change in sulfate due to, for instance, the reaction sulfur dioxide (SO<sub>2</sub>) with OH in the gas phase or the reaction with peroxide or ozone in the aqueous phase. PPTM tracks the changes separately for Aitken mode and accumulation mode aerosols. The level of detail is similar for all particulate matter components.

In this study, CMAQ/PPTM was used to quantify the contributions from selected source regions, which consist primarily of Santa Clara County and other neighboring San Francisco Bay Area (Bay Area) counties, to simulated deposition of nitrogen species to sensitive habitat areas in Santa Clara County.

Within the CMAQ model, PPTM requires the addition of duplicate model species variables for each source, source category, or source region that is to be tagged. The duplicated species may include PM-related sulfur, nitrogen, and secondary organic compounds, as well as primary organic carbon, elemental carbon, and other inorganic particulates. The tagged species have the same properties and are subjected to the same processes (e.g., advection, chemical transformation, deposition) as the actual (or base) species. For this study, the tagged species included all nitrogen species.

CMAQ numerically simulates the physical processes that determine the magnitude, temporal variation, and spatial distribution of the concentrations of each particulate species, including each tagged species. The simulation processes include advection, dispersion (or turbulent mixing), chemical transformation, cloud processes, and wet and dry deposition.

At each time step in the simulation, calculations are performed for the base species and the tagged species. Because the tagged species are separate from the base species, tagging does not alter or affect the base simulation results. The effects of linear processes, such as advection and dry deposition, are calculated directly for all tagged species. Potentially nonlinear processes, such as gas-phase chemistry, aqueous chemistry, and particle dynamics are calculated for the overall (or base) species and apportioned to the tagged species. The results for the tagged species are not normalized to ensure that the sum of the tagged species equals the total. Thus, the difference between the sum of all tags and the overall concentration gives an estimate of the numerical uncertainty in the contribution estimates. The tagged species are included as additional species in the model output files. A discussion of how PPTM is applied for each species and simulation process is provided in the user's guide (Douglas et al. 2007).

## Modeling Databases

The habitat areas of interest in this study are located within an area of approximately 400 km<sup>2</sup>. In order to distinguish the effects of sources local to the habitat areas from sources outside that area, a modeling database with a resolution on the order of 4 km is desirable. Databases with resolution more

resolved than 4 km are not available for this area. Resolution coarser than 4 km would make it difficult to resolve the area of interest and the emissions within that area. The identification of individual highways such as US 101 within the area surrounding the habitat is not attempted with the CMAQ modeling. The organization of emissions used in the CMAQ modeling does not allow the ready identification of individual roadways. Roadways are tagged collectively within Santa Clara County and within sub-areas of Santa Clara County. The effects of individual nearby roadways have been estimated using Gaussian models (see *Gaussian Modeling* section above).

CMAQ modeling databases for this study were acquired from CARB and from BAAQMD. The databases acquired from CARB included CMAQ-ready input files for an annual simulation of the year 2000 using a domain covering most of California. The results of this simulation were used solely to develop boundary conditions for a higher resolution simulation covering the Bay Area.

The BAAQMD provided a recently developed emissions inventory for the Bay Area counties. This inventory allowed preparation of CMAQ emissions files at 4-km resolution. For the portion of the modeling domain outside of Bay Area counties, emissions were derived from the model-ready files acquired from the CARB. Meteorological inputs for this domain were developed by CARB for a winter episode period covering December 17, 2000, through January 7, 2001, based on the California Regional PM10/PM2.5 Air Quality Study (CRPAQS) monitoring program. As a result of the limited availability of model-ready meteorological data, this was the only period modeled. A high-pressure system moved over central California late in the month of December. A front moved through during the period January 4–5, 2001. During the episode, therefore, the weather was dominated by high pressure. Winds were relatively light, and because it was winter, mixing heights were comparatively low. There was measurable rainfall in the San José area on only two days during the episode. The San José area is semi-arid and hence these conditions are fairly representative of average conditions in the area. Simulation of wet deposition is hindered by the lack of rainfall, but dry deposition is expected to dominate in this area due to the dry climate. Conversion of NO<sub>x</sub> to nitric acid would likely be more rapid during summer months, but mixing heights would be higher which would dilute emissions more rapidly. These effects would apply to all source categories similarly, however, so estimates of relative contributions to deposition would not be greatly altered by the simulation of a longer time period. The modeling domain is shown in Figure E-25.

**Figure E-25.** Modeling Domain for the CMAQ Simulations

Emissions were prepared from the BAAQMD emissions inventory using standard emissions processing procedures and the SMOKE Modeling System<sup>5</sup>. This processing provided emissions for the portion of the modeling domain made up of the Bay Area counties. Bay Area biogenic emissions were prepared using the BEIS3 processor. An emissions inventory consistent with the SMOKE software was not available for the rest of the modeling domain. Therefore, the

<sup>5</sup> SMOKE is a standard processing package used for preparation of emissions for CMAQ and other Eulerian grid models. For more information, see [www.cmascenter.org](http://www.cmascenter.org).

CMAQ model ready emissions files acquired from the CARB were used to define emissions in any grid cell outside of the Bay Area.

## Definition of Tags

Tags were defined to calculate the deposition from local sources in Santa Clara County, sources in the remainder of Santa Clara County, neighboring counties, and elsewhere in the modeling domain. The specific definitions of the tags are as follows.

**Table E-20.** Definition of Tags for Base-Year Modeling

Tag	Tag Description
Tag 1	Anthropogenic emissions originating in San Mateo County.
Tag 2	Anthropogenic emissions originating in Alameda County.
Tag 3	Anthropogenic emissions originating in Contra Costa County.
Tag 4	Anthropogenic emissions originating in San Francisco County.
Tag 5	Anthropogenic emissions originating in other Bay Area counties (Marin, Napa, Sonoma, and Solano).
Tag 6	Area source emissions for Santa Clara County originating in the Bay checkerspot butterfly habitat study area. (see Table E-9).
Tag 7	Mobile source emissions (road and nonroad) for Santa Clara County originating in the Bay checkerspot butterfly habitat study area.
Tag 8	Point source emissions for Santa Clara County originating in the Bay checkerspot butterfly habitat study area.
Tag 9	Anthropogenic emissions for Santa Clara County originating outside of the Bay checkerspot butterfly habitat study area (i.e., Santa Clara County emissions not included in Tags 6 through 8).
Tag 10	Initial and boundary concentrations for the 4-km modeling domain.
Tag 11	Biogenic emissions originating in the 8 Bay Area counties.
Tag 0	All emissions (anthropogenic and biogenic) for rest of the 4-km modeling domain not identified in tags 1–10.

The emissions for each tagged category are summarized in Table E-21. Although several different gaseous and particulate species are listed in the table, only the nitrogen containing species (NO<sub>x</sub>, NH<sub>3</sub>, and the particulate nitrate fraction of PM<sub>2.5</sub>) were subject to the tagging treatment. For reference, the emissions originating in San José are presented in Table E-22. (These emissions can be compared to the emissions for 2030 which are presented in the future-year tagging section. See Table E-25 in that section.)

**Table E-21.** Emissions Summary for Base Year (Average Daily Emissions for the Episode Period)

Tag	Tag Description	CO (tpd <sup>1</sup> )	NO <sub>x</sub> (tpd)	VOC (tpd)	NH <sub>3</sub> (tpd)	SO <sub>2</sub> (tpd)	PM2.5 (tpd)	PMC (tpd)

## Simulation Results

The simulated total nitrogen deposition (wet and dry combined) plot for the 22-day episode from December 17, 2000, through January 7, 2001, is presented in Figure E-26. This display presents a portion of the Bay Area which does not include the entire 185-by-185 grid cell modeling domain. The distribution shows peaks in deposition around the urban areas in the domain, including the San José area in the southern part of the Bay Area. These results are generally consistent with results from other studies such as Tonnesen and others (2007). It must be kept in mind, however, that these studies used different emission inventories and meteorological data files. The modeling also covered different time periods.

**Figure E-26.** Simulated Total Nitrogen Deposition (Wet and Dry) for the 22-Day Episode December 17, 2000 through January 7, 2001

The CMAQ simulation using PPTM provides estimates of the nitrogen deposition from each of the tagged sources of nitrogen listed in the previous section. Nitrogen deposition in all forms (ammonium, particulate nitrate, gaseous species such as NO, NO<sub>2</sub>, etc.) is included in the simulation, but, in the summaries provided here, species have been combined into overall total nitrogen. For the episode period simulated, the sources contributing to nitrogen deposition in the vicinity of Bay checkerspot butterfly habitats are summarized in Figure E-27. It should be noted that because the resolution of the model run is 4 km, the summary does not provide a deposition estimate specifically for the habitat area but rather an average over a 16 km<sup>2</sup> area that includes both habitat area and surroundings. In this case, we refer to the specific grid cell centered at latitude 37.19 N and longitude 121.68 W, which is marked on the map by a pink square.

**Figure E-27.** Simulated Contributions from Tagged Sources of Nitrogen Deposition in the Vicinity of Bay Checkerspot Butterfly Habitat (grid cell at latitude 37.19 N and longitude 121.68 W)

The simulated contributions to nitrogen deposition are spread across many different source categories, but the most important category is mobile source emissions in the vicinity of the habitat areas, contributing almost one-third of the total nitrogen deposition. Other source categories in the vicinity of the habitat also contribute to the total, with 13% coming from area sources within about 20 km of the habitat and 3% from point sources within about 20 km of the habitat. Sources in the remainder of Santa Clara County other than those near the habitat area contribute another 17% to the total nitrogen deposition. When all sources in Santa Clara County are considered, therefore, more than 60% of the total nitrogen deposition is accounted for.

Of the sources outside of Santa Clara County, the largest contributor at 20% is the tag representing sources in the modeling domain that are not in one of the Bay Area counties. This tag includes emissions from most of California (other than the Bay Area counties) except for a portion of southern California. This tag also includes a portion of Nevada.

Bay Area counties other than Santa Clara also contribute to nitrogen deposition in the habitat area. The contributions range from less than 1% (northern Bay Area counties are tagged collectively as other Bay Area counties) to 6% for Alameda County in this episodic simulation. Each of the other tagged counties (San Francisco, San Mateo, and Contra Costa) contributes 1–2% of the nitrogen deposition. The contributions simulated here for these individual counties could be dependent on the meteorological conditions during the episode that was simulated, and the relative contributions among these counties might vary for other time periods.

Figure E-28 shows the breakdown between simulated wet and dry deposition of nitrogen in the vicinity of the habitats. Deposition is dominated by dry deposition, which is consistent with the observed rainfall data during the episode period. Only two days during the episode had measurable rainfall. Annual deposition would likely be dominated by dry deposition, so the limited rainfall is not detrimental to our interpretation of the contributors to nitrogen deposition. Tonnesen et al. (2007) conducted annual CMAQ modeling that included the San José area. Tonnesen's simulations indicate annual dry deposition of between 47 and 811 kg-N/ha/y with less than 2 kg-N/ha/y of wet deposition. Monthly plots presented in their reports show a ratio of dry to wet deposition of at least 4:1 in January and at least 10:1 in July.

**Figure E-28.** Relative Contributions of Wet and Dry Deposition to the Total Nitrogen Deposition in the Vicinity of Bay Checkerspot Butterfly Habitat

The simulated contribution of various species to total nitrogen deposition in the vicinity of the habitats is summarized in Figure E-29. Nearly half of the deposition is from nitrate (including both particulate nitrate and nitric acid) with about 10% from ammonium. The remainder comes from other nitrogen species such as gaseous dry deposition of NO and NO<sub>2</sub>.

**Figure E-29.** Simulated Contributions of Species to Total Nitrogen Deposition in the Vicinity of Bay Checkerspot Butterfly Habitat

Because this is an episodic simulation, it does not directly provide an estimate of annual total nitrogen deposition. For the episode period (22 days), the simulated nitrogen deposition in the vicinity of the habitats is 0.40 kg-N/ha. In order to compare to other studies, we can scale this to a per annum figure by multiplying by the ratio of the number of days in a year to the 22 days in our simulation. This scaling yields an estimate of 6.6 kg-N/ha/y for the 16 km<sup>2</sup> area around Coyote Ridge. Other modeling estimates of deposition in the area such as *Impacts of Nitrogen Deposition on California Ecosystems and Biodiversity* (Weiss 2006), which conducted CMAQ modeling at 36-km resolution, present annual deposition estimates of a similar magnitude (6 kg-N/ha/y in the South Bay). The annual estimate of 6.6 kg-N/ha/y is also consistent with the estimate made on page 25 (5.9–6.4 kg-N/ha/y) in the section on Gaussian modeling based on current ambient NO<sub>2</sub> concentrations in the San José area. As noted above, the 4-km resolution CMAQ modeling by Tonnesen et al. (2007) showed nitrogen deposition in the range of 7–11 kg-N/ha/y.

## Future-Year Simulations

Projections were made for two future years for simulation with CMAQ: 2035 and 2060. The year 2035 was used because that is farthest out that the Association of Bay Area Governments projects population growth in the study area and the Bay Area. The year 2060 was used as the estimate of the end of the permit term for

the Santa Clara Valley Habitat Plan. The year 2060 thus represents the final “build out” in the study area of urban and rural development covered by the Habitat Plan.

Extrapolations of emissions were made for each of the Bay Area counties, for Santa Clara County minus the study area, for the San José area, and for the study area minus the San José area based on projected population growth. Projected population growth for 2035 for each of the counties and for the San José area (includes the San José sphere of influence) was taken from the Association of Bay Area Governments *Projections 2007: Forecasts for the San Francisco Bay Area to the Year 2035* (Association of Bay Area Governments 2006). Projected population growth for the study area was derived from census tract-level data provided by the Association of Bay Area Governments *Projections 2007* data. Tracts that fell entirely within the study area were fully included, and tracts that fell partially inside the study area were divided proportional to the amount of tract falling within the study area. Population projections for Santa Clara County minus the study area and for the study area minus the San José area were derived by subtraction of the study area population from the total population of Santa Clara County and by subtraction of the San José area from the study area population, respectively. All 2060 populations were calculated by identifying the annual average rate of population change from 2010 to 2035 and extrapolating out to 2060. The assumed growth projections are shown in Table E-23.

**Table E-23.** Growth Factors for Bay Area Counties Used to Extrapolate Emissions to 2035 and 2060

County	2035 Growth Factor	2060 Growth Factor
Alameda	1.34	1.60
Contra Costa	1.37	1.62
Marin	1.14	1.24
Napa	1.25	1.38
San Francisco	1.23	1.42
San Mateo	1.22	1.39
Solano	1.48	1.82
Sonoma	1.24	1.37
Santa Clara County Minus Study Area	1.29	1.50
San José Projection	1.51	1.90
Study Area Minus San José	1.34	1.45
Source for 2035 projections: Association of Bay Area Governments 2006.		

The area and mobile sources within each county were extrapolated. Point source growth was not projected because the supply of increased power demands due to factors such as population growth and increases in industrial activity would not necessarily be distributed proportionally to the increases in population. In addition, point sources were already estimated to be one of the smaller contributors to nitrogen deposition compared to mobile and area sources. Because a detailed emissions inventory outside of the Bay Area was not

available, projections were not made for other areas of the domain. The emissions outside of the Bay Area therefore remain at the base level in the future-year simulations. For this reason, and because the mobile source and area source projections do not take into account improvements in emissions control technologies or regulatory actions, the contributions estimated in this analysis may overestimate the role of local area and local mobile sources in the future. It is not clear whether overestimates of local increases in the total future nitrogen deposition might be offset by underestimates of increases due to sources outside of the Bay Area.

The tags for the future-year simulations were redefined in order to differentiate San José from the remainder of Santa Clara County. The tags used in the future-year simulations are shown below.

**Table E-24.** Tag Definitions for Future-Year (2035 and 2060) Simulations

Tag	Tag Description
Tag 1	Anthropogenic emissions originating in San Mateo County.
Tag 2	Anthropogenic emissions originating in Alameda County.
Tag 3	Anthropogenic emissions originating in Contra Costa County.
Tag 4	Anthropogenic emissions originating in San Francisco County.
Tag 5	Anthropogenic emissions originating in other Bay Area counties (Marin, Napa, Sonoma, and Solano).
Tag 6	Area source emissions originating in San José area.
Tag 7	Mobile source emissions (road and nonroad) originating in San José area.
Tag 8	Point source emissions originating in San José area.
Tag 9	Anthropogenic emissions originating in Santa Clara County minus study area.
Tag 10	Area source emissions originating in (non–San José) study area.
Tag 11	Biogenic emissions originating in Bay Area counties.
Tag 12	Mobile source emissions (road and nonroad) originating in (non–San José) study area.
Tag 13	Point source emissions originating in (non–San José) study area.
Tag 14	Initial and boundary concentrations for the 4-km modeling domain.
Tag 0	Emissions (anthropogenic and biogenic) for rest of the 4-km modeling domain.

The extrapolated future-year emissions are summarized in Tables E-25 and E-26 for 2035 and 2060, respectively.

<b>Total</b>		<b>12,349.3</b>	<b>2,854.8</b>	<b>2,654.7</b>	<b>673.2</b>	<b>203.7</b>	<b>819.2</b>	<b>1,796.1</b>

The overall simulated nitrogen deposition for the future simulations is displayed in Figure E-30 for 2035 and Figure E-31 for 2060. Note the increases in deposition in the Bay Area counties relative to the base simulation in Figure E-32. Deposition in other portions of the domain is relatively unaffected by the changes in Bay Area emissions.

**Figure E-30.** Simulated Total Nitrogen Deposition (Wet and Dry) for the 22-Day Episode December 17, 2000 through January 7, 2001 Using Bay Area Emissions Extrapolated to 2035

**Figure E-31.** Simulated Total Nitrogen Deposition (Wet and Dry) for the 22-Day Episode December 17, 2000 through January 7, 2001 Using Bay Area Emissions Extrapolated to 2060

For the episode period (22 days), the simulated nitrogen deposition in the vicinity of the habitats is 0.50 kg-N/ha in the 2035 simulation and 0.58 kg-N/ha in the 2060 simulation. These represent 25% and 45% increases relative to the base year. Scaled to per annum figures, these give 8.3 kg-N/ha/y in 2035 and 9.6 kg-N/ha/y in 2060.

Simulated contributions from the projected source categories in Santa Clara County to deposition are summarized in Figure E-32 for the base year (2005), 2035, and 2060. Deposition from each of the projected categories increases by about 30% in 2035 relative to the base and by about 50% in 2060 relative to the base. These increases are consistent with the extrapolated increases in emissions for these categories of sources. Similarly, the Bay Area counties other than Santa Clara (see Figure E-33) show increases in deposition in proportion to the increases in emissions.

In the base-year simulation, Santa Clara County sources within the study contributed 46% of the nitrogen deposition. This contribution increases to 49% in

2035 and 51% in 2060. The contributions from other Bay Area counties remain at about the same percentages as in the base year, while the percent contribution from sources outside of the Bay Area decreases to about 15% by 2060. Note that no growth was estimated for emissions outside of the Bay Area, so given the increase in Bay Area emissions, the relative contribution from sources outside the Bay Area would go down. It is therefore not known if these other sources would keep pace with the growth in Bay Area counties or not.

**Figure E-32.** Simulated Contributions from Tagged Sources to Nitrogen Deposition in the Vicinity of the Santa Clara County Bay Checkerspot Butterfly Habitat for the Santa Clara County Emission Categories (kg-N/ha/day)

**Figure E-33.** Simulated Contributions from Tagged Sources to Nitrogen Deposition in the Vicinity of the Santa Clara County Bay Checkerspot Butterfly Habitat for the tagged Bay Area counties (kg-N/ha for the 22-Day Episode Period)

The tags included in the base year simulation did not treat San José sources separately from other sources. In the future-year simulations, tags were added to separate San José emissions from other Santa Clara County emissions within the study area. The simulated contributions of these separate categories of sources are presented in Figure E-34. San José area sources, point sources and mobile sources combined, account for 57% of the nitrogen deposition within the Santa Clara County share of deposition. Of all nitrogen deposition sources (inside and outside Santa Clara County), San José point and mobile sources account for 38% of nitrogen deposition in 2035. Other areas within the study area account for 16% of the nitrogen deposition while the portion of Santa Clara County outside of the study area accounts for 27% of the nitrogen deposition. These relative contributions remain essentially unchanged in the 2060 simulation.

**Figure E-34.** Simulated Relative Contributions from Separate Santa Clara Source Categories to the Santa Clara County Share of Nitrogen Deposition in 2035<sup>6</sup>

<sup>6</sup> Impacts on nitrogen deposition from Morgan Hill and Gilroy were not explicitly identified in our modeling, but are part of the contribution referred to as the remainder of Santa Clara County. See discussion on p. 68 regarding impacts from these cities.

The relative contribution of wet versus dry deposition and from various species is similar in the future-year simulations relative to the base-year simulations (Figures E-35 through E-38). This is to be expected because the relative contributions of wet and dry deposition is driven by meteorological conditions during the period simulated. The distribution among species in the emissions files would be relatively unchanged in the future-year simulations because emissions of all species were extrapolated based on the same factors.

## Limitations and Uncertainty

Before considering the analytical approaches available to determine the effects of nitrogen deposition, one must understand the uncertainties associated with these methods. The amount and location of nitrogen deposition depends on many factors, which can be difficult to characterize precisely. Rates of nitrogen deposition vary with the location of nitrogen sources and the amount and

chemical form of nitrogen they emit, as well as on meteorological conditions (e.g., prevailing wind direction, precipitation), topography, and vegetation structure. The location, amount, and type of nitrogen emissions in the study area in the future are difficult to predict and characterize because of the complex combination of additional point and mobile emission sources that will result from urban and rural development and road construction under the Habitat Plan. An important example is the uncertainty of additional automobile emissions, which would be the primary source of new nitrogen deposition in the study area as a result of covered activities.

Emissions per vehicle can be expected to decrease over time as technology and emissions standards improve. However, the amount of this reduction is difficult to estimate because technological improvements are uncertain and may have unexpected effects. For example, the introduction of three-way catalytic converters in automobiles has reduced overall emissions of  $\text{NO}_x$ , but has increased emissions of  $\text{NH}_3$ , which has a higher deposition velocity and shorter transport range than  $\text{NO}_x$  (CH2M Hill 2004). The reader must bear in mind that the future year simulations reported here used emissions that were extrapolated from the base year without taking into account the expected improvements in motor vehicle emission control technologies, but also without the postulated, accompanying increase in ammonia emissions.

In addition to the uncertainties associated with the amount of nitrogen deposition that will occur as a result of covered activities, there is uncertainty associated with the degree of impact on covered species. Although it is clear that elevated rates of nitrogen deposition degrade serpentine communities, it is not clear to what extent the incremental addition of nitrogen over current levels will affect these communities and, ultimately, populations of covered species (Weiss 2006).

The CMAQ modeling reported here used a comparatively short time period. However, this time period is fairly representative of the average conditions in the area. In addition, use of a longer time period would not be likely to greatly alter the relative contributions of sources to nitrogen deposition.

The modeling analyses conducted here rely on established models that have been reviewed by the scientific community and evaluated in numerous applications in the past. Nevertheless, the representation of physical and chemical processes in the models can only be as good as current scientific understanding and may include unknown errors or shortcomings. In addition, the models rely on estimates of emissions, meteorological simulations, and limited sets of meteorological measurements as input data. As noted above, these meteorological and emissions estimates include some uncertainty. In this study, however, the model results were not used in an absolute sense to determine nitrogen deposition. Rather, we have used the models in a relative sense to assess the portion of the nitrogen deposition that is attributable to various categories of sources and the relative increase in nitrogen deposition that might be expected due to growth.

## Conclusions

In this study we have used several modeling approaches in order to estimate nitrogen deposition to the Bay checkerspot butterfly habitat area. Deposition based on the line source modeling can only provide estimates of deposition from the highways that were modeled. Estimates based on observed data includes contributions from all sources, but, since the monitors considered are not at habitat locations, the estimates may not be representative for specific habitats. Estimates based on CMAQ include all sources but are averaged over an area that includes both habitat areas and non-habitat areas. Estimates of overall deposition based on observations of NO<sub>2</sub> concentration and modeling using CMAQ both give estimates of total nitrogen deposition of about 6 kg-N/ha/y, which is consistent with other studies such as Weiss (2006). Modeling with CMAQ also provides estimates of expected increases in deposition in future years. Modeling with Gaussian models, while not providing an estimate of overall deposition, provides an estimate of deposition from individual roadways and the expected increases in deposition from those roadways in the future.

Based on the CMAQ modeling, should increases in NO<sub>x</sub> emissions occur in proportion to growth within the study area, within Santa Clara, and within the region, total average nitrogen deposition in the area around and including the habitat areas could increase to 8 kg-N/ha/y in 2035 (a 33% increase) and almost 10 kg-N/ha/y in 2060 (a 66% increase). Gaussian modeling indicates that, when emissions are extrapolated based on projected growth, contributions to nitrogen deposition from major roadways could increase by almost a factor of two by 2030 and by an even larger amount by 2060.

## Contributors to Deposition

The amount that various sources contribute to deposition was assessed with different modeling approaches. The most complete of these methods was the use of the PPTM tagging approach in CMAQ. In addition, however, Gaussian modeling provided estimates of the relative contributions of several major roadways to nitrogen deposition.

## Nitrogen Deposition from Santa Clara Valley Habitat Plan Covered Activities

In the base year, the CMAQ PPTM simulation attributes 30% of the total nitrogen deposition to mobile sources within the study area. Another 16% of the nitrogen deposition comes from stationary sources in the study area. Therefore, 46% of nitrogen deposition on the habitat areas comes from existing development and traffic generated locally within the study area. The remainder of Santa Clara County contributes 17% of the nitrogen deposition while the other eight Bay Area counties account for about 11% of the deposition.

The CMAQ simulation indicates that the remaining 26% of the N-deposition comes from anthropogenic emissions in the remainder of the modeling domain (i.e., most of the remainder of California other than Bay Area counties and a portion of Nevada), initial and boundary concentrations (i.e., effects from outside of the modeling domain), and biogenic emissions within the Bay Area counties.

Impacts on nitrogen deposition from Morgan Hill and Gilroy were not explicitly identified in our modeling, but are part of the contribution referred to as the remainder of Santa Clara County. In the emissions inventory used to prepare emissions for CMAQ, municipalities are not identified separately from the county in which they are located. Estimates of emissions for Morgan Hill and Gilroy were made based on the overlap of boundaries of these cities with grid cells in the modeling domain (see Table E-27). Since grid cells resolve emissions only to areas measuring 144 km<sup>2</sup>, this is necessarily an approximation. However, based on these estimates, the values in Table E-27 indicate that Gilroy contributes 2% of the Santa Clara County NO<sub>x</sub> emissions, Morgan Hill contributes 3%, San José contributes 79%, and the remainder of Santa Clara County contributes the remainder of the NO<sub>x</sub> emissions (16%). It is reasonable to assume that the impacts from Gilroy and Morgan Hill would be roughly in proportion to their emissions. Of the 17% contribution to nitrogen deposition noted for the remainder of Santa Clara County, therefore, we could expect Gilroy to make up about 1.5% (9% of 17%) and Morgan Hill to make up about 2.7% (16% of 17%).

**Table E-27.** Estimated NO<sub>x</sub> Emissions for Cities in Santa Clara County

City or Area	NO <sub>x</sub> Emissions (tpd)	Santa Clara NO <sub>x</sub> Emissions (%)	Non-San José NO <sub>x</sub> Emissions (%)
San José	52.07	79	
Gilroy	1.20	2	9
Morgan Hill	2.20	3	16
Santa Clara County, other than above	10.20	16	75
<b>Total</b>	<b>65.68</b>		

Increases in nitrogen deposition based on extrapolation of emissions to future years were simulated for Bay Area counties. Future-year emissions projections were not available for the remainder of the domain. The simulated nitrogen deposition in the area around and including the Bay checkerspot butterfly habitats (once scaled to per annum values) is 8.3 kg-N/ha/y in 2035 and 9.6 kg-N/ha/y in 2060, a 25% and 45% increases relative to the base year, respectively.

Contribution of mobile source emissions in the Bay checkerspot butterfly habitat areas are estimated to increase by about 0.6 kg-N/ha/y in 2035 over the base year (a 10% increase) and by another 0.5 kg-N/ha/y in 2060 (an 18% increase). The

San José contribution to nitrogen deposition in the habitat areas is estimated to be 38% in 2035.

Gaussian modeling of major roadways near the habitats indicates an increase in nitrogen deposition of about 0.25 kg-N/ha/y using emissions extrapolated to 2030 over the base year (a 4% increase in total deposition). The increase using emissions extrapolated to 2060 relative to 2030 could be from 0.4 kg-N/ha/y to more than 1 kg-N/ha/y depending on location (a 7% to 17% increase in total deposition).

## **Nitrogen Deposition from Outside Growth**

Only growth in emissions in Bay Area counties was considered in the CMAQ PPTM simulations because future-year emissions were not available for the remainder of the modeling domain. Gaussian modeling was limited to an area in the immediate vicinity of the habitats due to the limitations in scale of this type of model.

The contribution of emissions outside of the study area but within Santa Clara County are estimated to grow from 1.1 kg-N/ha/y in the base year to 1.5 kg-N/ha/y based on emissions extrapolated to 2035 (36% increase) and 1.7 kg-N/ha/y based on emissions extrapolated to 2060 (55% increase). The contribution of emissions from all other Bay Area counties are estimated to grow from 0.7 kg-N/ha/y in the base year to 0.9 kg-N/ha/y in 2035 (29% increase) and 1.0 kg-N/ha/y in 2060 (43% increase).

## **Effects of Nitrogen Deposition**

### **Effects on Serpentine Grassland**

The major effect of N-deposition on serpentine grassland is to promote invasion of nonnative annual grasses in the absence of grazing (Weiss 1999). Additional studies have been done since Weiss's study and are included in the Metcalf Energy Center Annual Monitoring reports (CH2M Hill 2002–2008), monitoring reports for the VTA mitigation lands (Harvey and Associates 2007), and USFWS funded research on Adaptive Management of Serpentine Grasslands in Santa Clara County (Weiss et al. 2007).

The effect is illustrated in the photo below (Figure E-39), taken in 1995 at the base of Coyote Ridge, just north of the Kirby Canyon Landfill. The right side of the fence was grazed, and the left side was ungrazed for 9 years (since 1986). Similar invasions have been noted and documented in the Silver Creek Hills, Tulare Hill, Santa Teresa County Park, and other sites (including small experimental plots).

The invasion occurs rapidly. Annual grasses build up over two to three years, eventually developing a thick layer of thatch that effectively smothers the native forbs. Native species cover and richness plummet across all but the thinnest soils. The major invasive grass species include Italian ryegrass (*Lolium multiflorum*) and soft brome (*Bromus hordeaceus*), with localized stands of common barley (*Hordeum*) spp. and compact brome (*Bromus madritensis*).

It is likely that invasions of barb goatgrass (*Aegilops triuncialis*) into serpentine soils are enhanced by N-deposition, but this species will invade serpentine soils in the absence of N-deposition.

Grazing management is essential. Grazing cattle select N-rich annual grasses and create bare soils that favor annual forbs. The existing grazing systems, documented elsewhere in the Habitat Plan and other management plans, have served well to maintain native diversity of serpentine grasslands. Typical stocking rates and seasonality include 1 cow-calf per 10–15 acres for winter-spring (rainy season) or summer-fall (dry season), with small modifications according to short-term seasonal variations. Cattle are moved from pastures that no longer supply enough grass to maintain cattle weight. Cattle can also keep barb goatgrass from completely dominating serpentine grassland if grazing occurs before the awns harden but after the other annual grasses have dried out.

Recovery with the reintroduction of grazing may take many years, as evidenced in the Silver Creek Hills (Wetlands Research Associates 2008). On Tulare Hill, Weiss and colleagues have noted that seedbanks from the final large cohort of native forbs in 2004 (3 years after the cessation of grazing) provided for dense native forb cover following a June 2004 fire on Tulare Hill (Metcalf Energy Center 2006). Once the native seedbank is depleted, restoration of high-quality serpentine grassland requires recolonization from forb-rich patches of thin soils, which is a much slower process.

The long-term effects of N-deposition are unknown, but the working hypothesis is that existing grazing regimes will be able to maintain diversity. However, recent research suggests that current levels of grazing may not be effective at maintaining native biological diversity or reducing invasive grass impacts under on-going nitrogen accumulation in serpentine grasslands (J. Pasari, pers. comm.).

It is estimated from roadside gradient studies at Edgewood that the critical load for intense grass invasions is on the order of 5 kg-N/ha/y (Weiss et al. in preparation). This level will likely be exceeded for several decades in Santa Clara County (where similar passive sampler methods estimate 10–20 kg-N/ha/y), with the higher levels in hotspots near freeways and urban fringe (Fenn et al. 2010).

**Figure E-39.** Invasion of Non-Native Annual Grasses due to Nitrogen Deposition at Coyote Ridge

## Effects on Bay Checkerspot Butterfly

Dense stands of dotseed plantain (*Plantago erecta*) across many slopes and soil depths is an essential condition for Bay checkerspot butterfly populations. Loss of host plants and nectar sources due to grass invasions leads to rapid declines and eventual local extinction of populations. Numbers in the Silver Creek Hills rapidly declined from tens of thousands to near extinction over a 3-year period (Weiss 1999). A population of 1,000–2,000 butterflies on Tulare Hill in 2002 dropped following cessation of grazing in 2001 over two-thirds of the hill and reduced the number of checkerspot to a tiny remnant population (1 adult sighted in each of the three years from 2006 through 2008).

## Effects on Serpentine Covered Plants

The main effect on covered plants to consider is their vulnerability to annual grass overgrowth. Brief assessments of these effects on covered plants are discussed below.

Santa Clara Valley dudleya (*Dudleya setchellii*) lives on rock outcrops and is relatively immune from grass invasions except when extremely tall grasses smother small rock outcrops. The species persists on medium to large rock outcrops in ungrazed areas (Weiss et al. 2008).

Metcalf Canyon jewelflower and most beautiful jewelflower (both subspecies of covered *Streptanthus albidus*) can be poor competitors against dense annual grasses (Green 2005), and some degree of grazing appears necessary to maintain populations. The two known populations of Tiburon paintbrush (*Castilleja affinis neglecta*) persist in grazed areas but likely would get overrun by dense grass growth if grazing were removed.

Mt. Hamilton thistle (*Cirsium fontinale* var. *campylon*) is a perennial that dominates serpentine seeps and persists in both grazed and ungrazed drainages. The annual grasses do not readily invade the active stream channels and the plant thrives in a variety of grazing regimes. Cattle avoid the sharp-spined leaves, but the physical disturbance in wet soils appears to encourage thistle recruitment.

Smooth lessingia (*Lessingia micradenia* var. *glabrata*) may be vulnerable to grass invasions but may have different dynamics because of its late-season (summer-fall) flowering.

Coyote ceanothus (*Ceanothus ferrisae*) is itself a nitrogen fixer and once established, is able to compete well with annual grasses. Fragrant fritillary (*Fritillaria liliacea*) is vulnerable to overgrowth by annual grasses but may persist as a bulb or vegetative state for many years before going locally extinct.

## Effects on Other Natural Communities

The effects of N-deposition on non-serpentine annual grasslands and the grassland understory of oak woodlands are similar to those on serpentine grassland—increased annual grass growth displaces native forbs. Non-serpentine annual grasslands and oak woodlands in the study are extensive (310,875 acres, or 60% of the study area), so these adverse effects could be widespread. Vernal pools appear to be particularly susceptible to overgrowth by grasses (Marty 2005), although vernal pool habitats have largely disappeared from the study area. Increased grass growth also increases fuel loads and subsequent fire intensity. Other grassland weeds such as yellow star thistle likely react positively to increased N-availability, since weeds have high growth potential and can rapidly respond to increased nutrient availability. Growth and spread of weeds are major issues for biodiversity conservation.

Appropriate grazing management to control annual grass biomass is necessary in these habitats. Increased weed management costs are likely for those weeds that cannot be controlled by grazing.

Long-term effects on shrublands, denser woodlands, and forests have not been locally observed, but these habitats should be more resistant to effects of N-deposition than are grasslands. Increased grass growth in sparse shrublands can change fire frequency and lead to conversion to annual grassland following short-interval fires. However, all ecosystems can be subject to N-saturation given long-term deposition loads, with the results being increased rates of N-cycling leading

to leaching of nitrate, gaseous emissions of NO, nutrient imbalances, and changes in composition as more nitrophilous species gain competitive advantage.

The leaching of nitrate from N-saturated systems may have impacts on local aquatic systems, but have not been studied in depth. For example, the Llagas aquifer and Llagas Creek are under a set of nitrate Total Maximum Daily Load (TMDL) limits. Initial calculations by Weiss (2008) using the 4 km CMAQ run (Tonnesen et al. 2007) suggest that total atmospheric N-deposition directly on the Llagas Basin (the Santa Clara Valley floor from Cochrane Road south, not including tributary streams) is similar to agricultural N-fertilizer inputs (150 vs. 120 tons/year). However, no direct links have been made at present and further research is needed.

## Effects on Water Quality

Water quality effects have not been studied in the region, but high nitrate has been observed in high deposition watersheds (20–50 kg-N/ha/y) in the Los Angeles basin (Fenn et al. 2003).

Appendix F

# **Climate Change and the Santa Clara Valley Habitat Plan**

## Appendix F

# Climate Change and the Santa Clara Valley Habitat Plan

Climate change is defined as any significant change in climate metrics, including temperature, precipitation, and wind patterns, over a period of time. Climate change—broadly speaking—may result from natural or human activities that change atmospheric composition. There is now broad scientific consensus that humans are changing the chemical composition of the earth’s atmosphere. Activities such as fossil-fuel combustion, deforestation, and other changes in land use are resulting in the accumulation of greenhouse gases (GHGs) such as carbon dioxide (CO<sub>2</sub>) in the atmosphere. An increase in GHG emissions is said to result in an increase in the earth’s average surface temperature, commonly referred to as *global warming*. Global warming is expected, in turn, to affect weather patterns, average sea level, ocean acidification, chemical reaction rates, precipitation rates, and other climatic conditions; such changes, taken collectively, are commonly referred to as *climate change*. Because climate change is predicted to have potential adverse effects on the natural environment, the effects of climate change in the context of the Santa Clara Valley Habitat Plan (Plan) are discussed in this appendix.

## Regulatory Context

To date there have been no significant environmental regulations enacted in the United States at the national level specifically designed to address climate change. However, several federal and state court decisions and pending cases anticipate the need for addressing climate change in future regulatory processes as a “changed circumstance.” Recent case law suggests that plan developers ignore climate change at their peril. In *Massachusetts v. Environmental Protection Agency* (2007), the Supreme Court sided with the petitioners, upholding that the potential threats of carbon dioxide (CO<sub>2</sub>) are sufficiently understood and should be regulated by the Clean Air Act, despite scientific uncertainty. Similarly, in *Natural Resources Defense Council v. Kempthorne* (2007), the courts contended that the uncertainty associated with climate change was not a reason to fail to address it in the context of a Biological Opinion under Section 7 of the federal Endangered Species Act (ESA) (Bernazzani et al. 2012).

In addition, some state and federal regulations and policies provide a framework within which climate change can be addressed. Below is a summary of these regulations and policies.

## **Endangered Species Act and No Surprises Policy**

Habitat Conservation Plans (HCPs) are required to address any changed circumstances that are reasonably foreseeable within the HCP permit term (63 Federal Register [FR] 35, February 23, 1998). Changed circumstances are defined by the U.S. Fish and Wildlife Service (USFWS) in the No Surprises Policy (63 FR 35, February 23, 1998) as “changes in circumstances affecting a species or geographic area covered by a conservation plan that can reasonably be anticipated by plan developers and the Service and that can be planned for.” The No Surprises policy ensures that no additional land-use restrictions or financial compensation will be required of the permit holder as long as the plan is being properly implemented.

## **Natural Community Conservation Planning (NCCP) Program**

Like the ESA, the Natural Community Conservation Planning (NCCP) program is tasked with sustaining species and their habitat and maintaining viability of listed species. The NCCP Act is broader in its orientation and objectives than both its federal counterpart and the California Endangered Species Act. The NCCP Act includes provisions to contribute to the recovery of listed species and to specifically address natural communities and ecological processes.

“Changed circumstances” are also a component of NCCPs and are defined by the NCCP Act as “reasonably foreseeable circumstances that could affect a Covered Species or geographic area covered by the plan.” Accordingly, an NCCP must “incorporate a range of environmental gradients (such as slope, elevation, aspect, and coastal or inland characteristics) and high habitat diversity to provide for shifting species distributions due to changed circumstances.” [Section 2820(a)(4)(D)].

Prior to 2010, approved HCPs or NCCPs did not typically address climate change as a changed circumstance (Bernazzani et al. 2012). However, as general scientific consensus emerges regarding human-induced changes to the atmosphere, it can be assumed that climate change is now “reasonably anticipated” and must therefore be addressed along with measures that would be taken by the Permittees to respond to those changes. USFWS regulations require that HCPs and NCCPs take potential “changed circumstances” into account in the Plan, along with measures to address these changed circumstances.

## California Assembly Bill 32

In 2006, the State of California passed into law the Global Warming Solutions Act of 2006, commonly referred to as Assembly Bill 32 (AB 32), which is designed to significantly reduce short- and long-term greenhouse gas emissions generated by California. AB 32 states that global warming poses a serious threat to the environment of California.

## Guidance

Over the past decade, there has been a growing recognition at national, state, and local levels of the need to consider climate change in natural resource management and conservation planning. Nationally, federal agencies such as the USFWS, Government Accountability Office (GAO), the U.S. Global Change Research Program (GCRP), and the U.S. Environmental Protection Agency (EPA) have released reports calling for natural resource management that increases the resilience of ecological resources to climate change (Global Change Research Program 2009; U.S. Environmental Protection Agency 2009). Resilience refers to the amount of change or disturbance that an ecological system can absorb without undergoing a fundamental shift to a different set of structures and functions (Julius et al. 2008). A fundamental goal of climate change adaptation is to reduce the risk of adverse environmental outcomes by increasing the resilience of ecological systems.

In 2009, Congress asked the White House Council on Environmental Quality (CEQ) and the U.S. Department of the Interior (DOI) to develop a national strategy for helping the nation's natural resources adapt to climate change. This draft strategy, released in January 2012 (Council on Environmental Quality and U.S. Department of the Interior 2012), is the first joint federal, state, and tribal effort to identify adaptation strategies. It identifies some of the key actions that agencies should consider implementing over the next five to ten years.

Even prior to the release of federal guidance, the State of California developed its *Climate Adaptation Strategy*, which focuses on a multi-sector approach to respond to the current and future impacts of climate change. California was one of the first states to pursue a multi-sector state wide adaptation strategy and many of the objectives are being implemented today. The California Department of Fish and Game (CDFG) has created a Climate Science and Renewable Energy Branch with a climate science program that specifically works to plan for and respond to the effects of climate change on the state's fish and wildlife and their habitats. In September 2011, the CDFG released their vision for confronting climate change in California, which highlights an approach centered around 1) Unity: creating and maintaining vital climate change partnerships and collaborations, 2) Integration: integrating climate change into CDFG activities, and 3) Action: meeting conservation objectives for maintaining healthy ecosystems while taking into account climate change threats and impacts. In addition, within this vision the CDFG has detailed multiple mechanisms for incorporating climate change into natural resource planning, including national,

regional and local coordination, particularly around Landscape Conservation Cooperatives; California's Wildlife Action Plan; and the NCCP program. The NCCP program is one of the few existing planning programs put into law that addresses climate change adaptation.

## Observed Climate Change

The Earth's climate varies naturally over many temporal and spatial scales as a result of meteorological processes such as changes in atmospheric circulation patterns. *Climate variability* refers to deviations from the average climate, whereas *climate change* refers to changes in the long-term average, generally based on averages of twenty to thirty years.

Climate change is occurring as a result of high concentrations of greenhouse gases in the Earth's atmosphere (National Research Council 2010; Intergovernmental Panel on Climate Change 2007). Greenhouse gases include water vapor, carbon dioxide, methane, nitrous oxide, chlorofluorocarbons, and ozone. These gases absorb energy emitted by the Earth's surface, and then re-emit some of this energy back to Earth, warming the Earth's surface, and influencing global and local climates. As more and more greenhouse gases are emitted into the atmosphere from human activities such as the burning of fossil fuels, the Earth's energy balance is disrupted, resulting in a number of changes to the historical climate. Evidence of long-term changes in climate over the twentieth century includes the following (Intergovernmental Panel on Climate Change 2007; National Research Council 2010; Global Change Research Program 2009):

- An increase of 0.74 degree Celsius (°C) (1.3 degrees Fahrenheit [°F]) in the Earth's global average surface temperature;
- An increase of 0.17 meter (6.7 inches) in the global average sea level;
- A decrease in arctic sea-ice cover at a rate of approximately 4.1% per decade since 1979, with faster decreases of 7.4% per decade in summer;
- Decreases in the extent and volume of mountain glaciers and snow cover;
- A shift to higher altitudes and latitudes of cold-dependent habitats;
- Longer growing seasons; and
- More frequent weather extremes such as droughts, floods, severe storms, and heat waves.

# Observed Climate Change in California

## Temperature

The western United States has warmed at a faster rate compared to the national average (Moser et al. 2009). From 1949–2005, California's average annual mean temperature was approximately 12°C (56°F). Over the twentieth century, California has experienced an increase in this average of roughly 0.8°C (1.5°F), with some variability in the rate of warming within the state (see Figure F-1).<sup>1</sup> The warming trends are asymmetrical, with nighttime minimum temperatures rising faster than daytime maximum temperatures, and winter/spring seasonal temperatures experiencing greater warming compared to summer/fall (Nemani et al. 2010; Gershunov et al. 2009). Some locations within California are no longer frozen at night during winter (Moser et al. 2009).

**Figure F-1.** Change in Annual Mean Temperature (°F) for California for the Twentieth Century Relative to 1949–2005 Baseline

<sup>1</sup> The Western Regional Climate Center provides monthly, seasonal, and annual averages of temperature and precipitation for California and subregions within the state. The monthly station data, taken from cooperative observers (COOP), along with gridded data from the PRISM database, are used to assess climate across the state. Note that a limited number of stations were reporting prior to 1918.

In spring, summer, and fall the pattern of twentieth-century warming has been similar, according to an analysis available from the Western Regional Climate Center presented in **Table F-1** below (Abatzoglou et al. 2009). Across California, spring has been arriving earlier in the year and fall has occurred later (Moser et al. 2009). The frequency of heat waves also has been increasing, and it is generally becoming more humid (Gershunov et al. 2009).

**Table F-1.** Seasonal Temperatures (°F, 1949–2005) and Twentieth Century Trends (Δ°F) for California

Season	Seasonal Temperature (°F, 1949-2005) and Twentieth Century Trends (ΔF, in Parentheses)		
	Minimum Temperature	Maximum Temperature	Mean Temperature
Winter (DJF)	32 (1.4)	53 (1.0)	43 (1.2)
Spring (MAM)	41 (1.8)	66 (1.4)	53 (1.6)
Summer (JJA)	55 (2.6)	86 (0.6)	70 (1.6)
Fall (SON)	44 (2.2)	71 (0.9)	58 (1.5)

## Precipitation

Over the twentieth century, California, however, has experienced a statewide increase in annual precipitation of approximately 3.5 inches (Abatzoglou et al. 2009). Figure 2 shows the year-to-year variability of annual precipitation compared to the 1950–2005 average of 23 inches (indicated by the dashed line). **Table F-2** provides the seasonal precipitation averages and twentieth-century trends.

## Projected Climate Change in California

Scientists use global climate models to simulate current climatic conditions and to project the future climate. The models incorporate state-of-the-science understanding of earth processes (e.g., biogeochemistry of ecosystems on land and in the ocean) and are based on fundamental physical, atmospheric and oceanographic principles. Overall, scientists have greater confidence in the ability of climate models to simulate changes in temperature and less confidence about precipitation, especially regional precipitation patterns and other climatic

variables that are affected by local conditions such as topography (Global Change Research Program 2009), which is not accounted for in current models (Intergovernmental Panel on Climate Change 2007).

By mid-century, the average annual mean temperature in California is projected to rise from 1.1°C (2°F) to more than 2.8°C (5°F), with little to no change in total annual precipitation (Luers et al. 2006). There is significant variability in the precipitation projections by individual model and emissions scenario. Individual simulations suggest that there could be up to a 10 to 20% decrease in total annual precipitation (Luers et al. 2006).<sup>2</sup>

## Effects of Climate Change on Ecological Processes in the Study Area

Both land cover types and covered species within the study area are vulnerable to climate change based on their ecology and natural history. While temperature rise in itself will have direct consequences on species viability and natural community distribution and composition, the effects of global warming on the amount and timing of precipitation and the frequency of severe weather and related disturbance events are also likely to affect the study area and, as a result, the natural communities, covered species, and the Plan's proposed conservation strategy. These potential effects of climate change are discussed below.

### Precipitation

Several of the land cover types in the study area will be influenced by continuing shifts in the amount and timing of precipitation, with effects on soil moisture available for plants, runoff and ground water recharge, and sediment movements from the hillsides to the watershed drainage areas. Two climate models and predictions of climate change for Northern California are widely accepted by scientists (Suttle and Thomsen 2007; Dukes and Shaw 2007). Both models predict increases in the annual total amounts of precipitation and in each rainfall event, but differ in timing changes. In one model, the typical mid-winter rain-free period would decrease. Changes in precipitation patterns would affect land cover types differently. In grasslands, mature native bunchgrasses have deep roots and can access water during short dry periods (Holmes and Rice 1996), but seedlings with shallow roots may not be able to survive during these periods. Therefore, a reduction in the mid-winter rain-free period could favor seedling establishment of native grasses. Woody plant seedling establishment could be similarly favored (Dukes and Shaw 2007). This could improve the native grass component of the

<sup>2</sup> The California Climate Change Center report summarizes projections using the National Center for Atmospheric Research Parallel Climate Model (PCM1), Geophysical fluids Dynamic Laboratory (GFDL) CM2.1, and the United Kingdom Met Office Hadley Centre Climate Model, version 3 (HadCM3) under the Intergovernmental Panel on Climate Change (IPCC) Special Report on Emission Scenarios (SRES) B1 (low emissions), A2 (moderately-high emissions), and A1Fi (high emissions).

grasslands, increase shrub encroachment into the grasslands, and increase oak regeneration. However, increases in annual precipitation may favor the encroachment of mixed evergreen forests on areas of chaparral and oak woodlands (Lenihan et al. 2003). Redwoods and close-coned pines would expand from remnant, fragmented groves into surrounding oak woodlands and chaparral land covers.

In the second model, the rainy season would be extended from spring to summer, thus potentially benefiting native grasses and summer annual forbs, including summer wildflowers and the pest plant, yellow starthistle (*Centaurea solstitialis*). Increased herbaceous and woody biomass growth in response to increased precipitation would pose the risk of higher fire hazards. More frequent drought years are also predicted which in combination with more intense rainfall events would pose higher risks of soil erosion and drops in ground water levels. Temperatures are also predicted to increase (Dukes and Shaw 2007). As temperatures increase, non-native grasses would become more dominant and invasive.

## Increased Risk of Fire, Flooding, and Drought

California could experience a 55% increase in wildfire risk by mid-century (Luers et al. 2006). Many factors influence the likelihood of fires, including precipitation, winds, temperature, and vegetation. For some locations, increasing precipitation and temperatures may stimulate increased vegetation growth through a portion of the year, creating more fuel to burn later; other locations may experience decreasing precipitation and increasing temperatures, creating dry vegetation that can burn easily (Luers et al. 2006). Simulations indicate that the probability of fires greater than 500 acres increases under wetter conditions and decreases under drier conditions (Westerling and Bryant 2008).

The distribution and composition of vegetation communities may change due to increased fire activity (Brown and Hebda 1998). In the study area this could result in an increase in grasslands over woody land cover types (Lenihan et al. 2003).

Increased drought and flooding could also occur. Drought would reduce water availability for covered species and could in and of itself change natural community composition and distribution. Flooding could result from extreme rainfall events. Increased flooding could compromise the ability to restore streams and riparian areas and would have an unknown effect on aquatic species and natural communities.

# Effects of Climate Change on Species, Natural Communities, and Ecosystems

Several ecological responses to climate change have occurred during the past century. Most studies use species response to changes in temperature as the indicator of the effects of climate change. These responses, in concert with historic and predicted climatic changes, serve as the basis for identifying species, natural community and ecosystem vulnerabilities and predicting how individual species, natural communities, and the ecosystem will be affected by climate change in the study area. Four broad mechanisms of biological response to climate change are discussed below.

## Phenology

Phenology is the timing of seasonal events such as migration, flowering, and egg laying. Changes in phenology are reflected in shifts in the timing of events, potentially leading to phenological mismatch—that is, events that previously occurred at the same time would occur at different times. An example of phenological mismatch is the hatching of butterfly larvae *after* the peak flowering of host plants. Many studies have confirmed that the timing of biological events has shifted with changes in climatic conditions during the past few decades (Walther et al. 2002; Root et al. 2003; Root et al. 2005; Forister and Shapiro 2003). In general, species have demonstrated a phenological shift of  $4.2 \pm 0.2$  days/decade earlier at the middle latitudes ( $32^{\circ}$ – $49.9^{\circ}$ ) and  $5.5 \pm 0.1$  days/decade earlier at the higher latitudes ( $50^{\circ}$ – $72^{\circ}$  N) (Root et al. 2003). Phenological shifts are expected to increase as global climate change intensifies.

## Range and Distribution

Range is the area over which a species occurs or can potentially occur; distribution refers to where a species is located within its range. Range shifts can occur when a species moves from one location to another or expands its area due to changes in the environment (e.g., climatic variables, availability of food sources). A species' distribution can change in location and the number of disjunct populations within its range. Documented changes over the past century include shifts in dominant vegetation and in the documented ranges of butterflies and birds (Parmesan 1999; Pimm 2001; Walther et al. 2002; Easterling et al. 2000). Changes in range and distribution are especially problematic given the present fragmented character of species habitats. Shifts in range or distribution can isolate populations from one another, making them more vulnerable to genetic drift or local extinction. The shifting range of a species can also make previously protected areas unsuitable. Finally, narrowly distributed species (e.g., Bay checkerspot butterfly, Mount Hamilton thistle) and natural communities that already have restricted ranges due to urban growth, altitudinal gradients, or dependence on narrow environmental gradients are particularly vulnerable

because they likely have nowhere to move if their habitat becomes less suitable (Shainsky and Radosevich 1986; Murphy and Weiss 1992; Parmesan 1999; Pimm 2001; Walther et al. 2002; Easterling et al. 2000; Hillman pers. comm.).

## Abundance

Abundance is the number or density of individuals found in a particular location. Shifts in abundance can occur when climatic variables alter microhabitats, juvenile survival, resource availability, competition, and species dominance (Martin 1998; Walther et al. 2002; Millar et al. 2006). Documented changes include shifts in species density due to changes in resource availability and climatic gradients, decrease in species abundances due to increases in diseases and pests, and decrease in native species abundance due to increased competition from invasive species (Dukes and Mooney 1999; Millar et al. 2006; Pounds et al. 2006).

## Morphology and Genetics

Morphology is the study of form and structure in organisms; genetics is the internal code that governs morphology and behavior. Over very long time horizons, evolution changes morphology (and genetic frequency) to enhance species survival. Because these adaptations typically occur more slowly than do the environmental changes anticipated to result from climate change, many species will have difficulty adapting to climate change, resulting not only in a loss of genetic variability but in extinction of some populations and entire species as well (Davis and Shaw 2001).

## Land Cover Types

Land cover types with isolated ranges are most susceptible to climate change. In the study area, these land cover types are ponderosa pine woodlands, knobcone pine woodlands, redwood forest, lower-elevation scrub, and serpentine grassland. With the exception of lower-elevation scrub, regeneration of these land cover types is disturbance driven. Most commonly, fire frequency and intensity determine each community's ability to regenerate. Rises in sea level could restrict the range of lower-elevation scrub by flooding out lower elevations. Changes in fire regime and rise in sea level, along with other climatic variables that may increase or decrease environmental stressors, will either lead to expansion or reduction of these land cover types with isolated ranges.

## Ponderosa Pine Woodlands

Ponderosa pine woodlands have a limited distribution in the study area, occupying approximately 419 acres, or 0.1% of the study area. The stands are relics of a wider historic distribution during a cooler climatic period. Increased fire frequency could benefit the ponderosa pine community because the species is fire adapted. However, temperature rise is likely to further restrict the range of ponderosa pines by favoring species that thrive under warmer conditions. Ponderosa pine woodlands provide modeled habitat for three covered animal species (California tiger salamander, California red-legged frog, and western pond turtle).

## Knobcone Pine Woodlands

Knobcone pine woodlands occur only on the Santa Cruz Mountain ridgetops, often on serpentine-derived soils, at the western edge of the plan area, where they occupy approximately 711 acres, or 0.2% of the study area. The climatic conditions of marine fog, along with the water-retaining properties of serpentinite, allow continued persistence of knobcone pines in these locations (Vogl 1973). As an obligate fire-climax species, knobcone pines depend on periodic fires for regeneration. Fire allows for the release of seeds from the serotinous<sup>3</sup> cones, as well as creation of the bare mineral soil required for seed germination. Knobcone pine woodlands are bordered by chaparral at lower elevations and redwood or Douglas-fir at higher elevations. An increase in fire frequency and favorable climatic conditions could benefit knobcone pine. Conversely, if fires are too frequent, there is a risk that knobcone pine seedlings would be killed before producing seeds, thus jeopardizing the viability of the natural community. Knobcone pine woodlands provide habitat for three covered animal species (California tiger salamander, California red-legged frog, and western pond turtle).

## Redwood Forest

Redwood forest occupies approximately 9,693 acres, or 2% of the study area, in the Santa Cruz Mountains along creeks and valleys and on lower north- and east-facing slopes in the foothills. Although found in moist microclimates like knobcone pine woodland, redwood forest depends on fog to fulfill its moisture needs (Dawson 1998) and on fire for regeneration. In addition to fire, disturbances such as tree fall gaps and flooding also favor regeneration. Expansion of redwood forests could occur with increased fire frequency, although it is unclear how fire would affect the mosaic of redwood forest, knobcone pine, chaparral, and ponderosa pine, all of which are fire-adapted communities. Redwood forest provides habitat for four covered animal species:

---

<sup>3</sup> Serotinous cones require fire to open and release the seeds they contain.

California tiger salamander, California red-legged frog, foothill yellow-legged frog, and western pond turtle.

## Serpentine Grassland

The presence of serpentine soil limits the distribution of serpentine grassland, which includes serpentine bunchgrass grassland, serpentine outcrops, and serpentine seeps. Serpentine soils provide habitat for a number of native grassland species because the extreme soil conditions allow natives to outcompete invasive European grasses. While changes in climatic conditions may not affect the extent of serpentine grassland as a whole, changes in microclimate conditions could lead to changes in species composition and dominance. Serpentine bunchgrass grassland occupies approximately 10,308 acres, or 2% of the study area. Serpentine outcrops occupy approximately 260 acres, 0.1% of the study area and provide habitat for four covered plants (Metcalf canyon jewelflower, most beautiful jewelflower, smooth lessingia, and Santa Clara Valley dudleya). Serpentine seeps—small wetlands located within serpentine grasslands and coastal scrub—occupy approximately 34 acres, or 0.01% of the study area and provide habitat for seven covered animal species (Bay checkerspot butterfly, California tiger salamander, California red-legged frog, western burrowing owl, western pond turtle, tricolored blackbird, and San Joaquin kit fox) and three covered plant species (smooth lessingia, most beautiful jewelflower and Mt. Hamilton thistle), of which one—Mt. Hamilton thistle—is restricted solely to serpentine seeps.

## Lower-Elevation Northern Coastal Scrub/Diablan Coastal Scrub

In the study area, northern coastal scrub/Diablan coastal scrub (coastal scrub) is found throughout the Santa Cruz Mountain and the Diablo Range, usually below elevations of 300 feet on south-facing slopes (California Partners in Flight 2004). Increases in sea level would decrease the range and distribution of this natural community if climatic conditions and habitat connectivity did not allow for upslope expansion. Coastal scrub occupies an estimated 10,306 acres, or 2% of the study area. Covered plants that may be found in this community include fragrant fritillary, and coyote ceanothus. Coastal scrub provides habitat for California red-legged frog and western burrowing owl.

## Covered Species

Life history, behavioral characteristics, and habitat requirements predispose certain covered species to be more susceptible to climate change than others. Within the study area, the species most vulnerable to climate change are those with limited dispersal ability, slow reproductive rate, specific habitat or soil

requirements, and limited habitat connectivity, as well as those already at the extreme of their range. Moreover, those species for which the study area includes a high proportion of their range or those for which critical habitat has been designated within the study area are of particular concern. For this analysis, covered species have been grouped into four categories on the basis of these characteristics and the ecological responses discussed above: butterflies, amphibians, reptiles, and plants. The four groups comprise a total of 10 species: Bay checkerspot butterfly, California red-legged frog, California tiger salamander, foothill yellow-legged frog, western pond turtle, coyote ceanothus, Santa Clara Valley dudleya, Metcalf Canyon jewelflower, Mount Hamilton thistle, and smooth lessingia (**Table F-3**). This analysis discusses the life history, behavioral characteristics, and habitat requirements that predispose these species groups are to be particularly susceptible to climate change.

## Butterflies

Butterfly species are sensitive to climate change due to their larval host plant and nectar-source dependence (Murphy and Weiss 1992). If the timing of host-plant availability changes without equal shifts in life-cycle timing, the phenological mismatch could affect reproductive success. In addition, the narrow habitat requirements of butterflies and host plants may lead to shifts in range, distribution, and abundance as a result of climate change.

In the study area, climate change has the potential to affect Bay checkerspot butterfly, a covered species under the Plan (**Table F-3**). This species occurrence is restricted to narrow environmental gradients, with the majority of its habitat located in the study area. Additionally, 16,601 acres or 91% of designated critical habitat for the species is located within the study area (66 FR 21450–21489).

## Amphibians

Amphibians' permeable skin, biphasic life cycles, and unshelled eggs make them sensitive to small changes in temperature and moisture (Carey and Alexander 2003). In most cases, amphibians in temperate climates can tolerate wide variations in temperature, but their dependence on aquatic environments for reproductive success could be comprised by changes in seasonal and regional climatic patterns. Decreases in precipitation or shifts in timing of precipitation would have an effect on reproductive success and adult survivorship due to increased risk of desiccation, reduced food supply, and increased predation due to reduced habitat availability. Such changes could lead to a range shift and changes in distribution and abundance. Increased evaporation of aquatic habitat due to increased temperatures could have indirect effects, such as the concentration of toxic chemicals that could lead to increased mortality and decreased reproductive success (Davidson et al. 2001; Carey and Alexander 2003).

In the study area, climate change has the potential to affect three covered amphibian species: California red-legged frog, California tiger salamander, and foothill yellow-legged frog (**Table F-3**). California red-legged frog and California tiger salamander both have limited dispersal ability and are dependent on the proximity and connectivity of aquatic environments with their upland habitat for reproductive success. Of the designated critical habitat for California red-legged frog, 150,962 acres (9%) is within the study area. Critical habitat for the Central population of California tiger salamander encompasses 28,096 acres, or 14% of the study area. Because foothill yellow-legged frog is not federally listed, critical habitat has not been designated. Nevertheless, the species has limited dispersal ability and is restricted to aquatic environments. Reproductive success is dependent on a narrow range of in-stream environmental gradients (e.g., temperature and stream flow velocity).

## Reptiles

The potential effects of climate change on reptiles are less well studied than its effects on amphibians. Some reptiles exhibit temperature-dependent sex determination, whereby increased air temperatures skew the sex ratio to favor females over males (Janzen 1994). If such a phenomenon applies to covered reptile species in the study area, global warming could result in a preponderance of females in the study area.

In the study area, climate change has the potential to affect western pond turtle (**Table F-3**). Gender shifts would not be notable until later in the permit term as this species is long lived and does not reach sexual maturity until at least 10 years of age. No critical habitat has been designated for this species and its range extends well beyond the study area.

## Plants

Even more than wildlife, plants are vulnerable to climate change. Changing the habitat conditions that are necessary for persistence of a given sensitive plant species (e.g., increased temperature, increased or decreased moisture) could result in extinction if the species' minimal habitat requirements are not met, or if the habitat becomes more favorable for other species (Hillman pers. comm.). Day length, temperature, moisture conditions, and the presence of the appropriate pollinators all play a critical role in reproductive timing and success. The dependence of plants on seed dispersal for movement across habitats and climatic gradients prevents them from moving quickly in the face of changing climatic conditions and habitat suitability. In addition, the specific soil requirements and physiological tolerance limits of plants along with limited habitat connectivity make plants particularly susceptible to climate change. All of the covered species in the study area have some degree of affinity for serpentine soils and most are dependent on serpentine soils for their habitat requirements (**Table F-3**).

## Conservation Strategy

Conservation biology is the basis of the conservation strategy, and the proposed reserve design anticipates some effects of climate change using a multi-scale approach. As such, it is designed to reduce species vulnerability and provides opportunities for species and natural communities to adapt in responses to climate changes. Biological goals and objectives were developed at the *landscape level* to encompass ecological processes, environmental gradients, biological diversity, and regional wildlife linkages. Conservation actions were developed to implement these goals and objectives. Landscape-level objectives and actions are generally developed at the scale of miles or tens of miles. By working at the landscape level, flexibility for climate change–driven shifts in range and distribution of species and natural communities is allowed. This landscape level approach allows for replication of ecosystems and populations to achieve a balance representation of natural communities and species habitats, support multiple species within the Reserve System, and protect of key ecosystem features. Land acquisition will target properties that provide connectivity within the Reserve System and among existing protected areas within and outside the study area and rural private lands. This will allow for northward and upslope movement, maintain and restore habitat linkages, and reduce fragmentation. In addition, habitat types across environmental gradients (topographic diversity) are targeted to provide topographic diversity and reduce the chance of population extinction (Murphy and Weiss 1992). Protection of a range of environmental gradients allows natural communities and species to adapt to changes in temperature and precipitation. It provides an opportunity for movement to areas where environmental conditions remain favorable for their persistence if climate change causes their current location to become unfavorable. Protection of key ecosystem features (i.e., riparian, aquatic) throughout the study area ensures that vulnerable species such as amphibians will have available habitat across a variety of environmental gradients. In addition, removal of barriers (i.e., fences and medians) and creation of safe passage ways (i.e., culverts under roads) within the study area will increase the permeability of the landscape to allow for species movement through and within the study area. Both increased landscape connectivity and permeability allow for species migration to occur across the landscape. Consequently, some species and natural communities within the study area would be able to “move” in response to climate change, allowing for shifts in range and distribution.

Conservation actions were also developed to address natural communities primarily through the enhancement, restoration, and management of vegetation types (i.e., land cover types). This medium scale is called the *natural community level*. Enhancement, restoration and other land management actions would increase the resilience of natural communities in the face of climate change. For example, grazing can be managed to provide some control of increasing shrub encroachment and pest plants, but an integrated program including non-grazing methods will be needed. Specific actions that would increase resilience include controlling invasive species and diseases through integrated pest and vegetative management, and improving habitat quality to increase resource availability for native species.

Finally, the specific needs for protection and enhancement of individuals, populations, and groups of populations of covered species were addressed. *Species-level* conservation actions were developed to supplement and focus actions developed at the broader scales and to ensure that all the needs of each covered species are addressed. Species-level conservation measures have a habitat focus. Examples include protection of specific habitat elements to allow for plant population expansion and creation. These species-specific actions would ensure that populations of each covered species are maintained, and monitoring would identify any early negative trends caused by climate change.

While the conservation strategy can help to ensure the movement of some communities across the landscape and can address through management actions, some of the effects of climate change are beyond the control of management or land acquisition. The conservation strategy cannot address changes in phenology, nor in morphology and genetics. For example, the serpentine communities are adapted to persist on serpentine soils. It is outside the scope of the conservation strategy to genetically modify these plants so that they can outcompete nonnative grasses on other soil types. Additionally, some responses, in terms of connectivity, are needed at scales greater than the Plan can provide and would necessitate planning in multiple counties. While the Plan can combat small shifts in range, distribution, and abundance at the landscape, natural community, and species levels, larger shifts due to climate change would extend outside the study area.

## Adaptive Management and Monitoring

The Adaptive Management and Monitoring Program enables the conservation strategy to respond to the effects of climate change. Landscape-level monitoring is designed to detect large-scale changes, such as changes in ecosystem processes, shifts in natural community distribution, and the integrity of landscape linkages. Community-level monitoring, in turn, is designed to detect changes in the composition and function of natural communities, populations of key predator or prey populations, invasive species, and other important habitat factors for covered species. Finally, species-level monitoring measures the effects of management actions on covered species abundance and distribution, as well as, the status and trends of covered species in the Reserve System. Collectively, these monitoring actions will allow for early detection and response to the effects of climate change, such as early identification of stressors (i.e., fire, flood, drought, pollution), increased abundance and distribution of invasive species, and changes in range, distribution, and abundance of natural communities and covered species. Both the conservation and monitoring actions described above will help to buffer the effects of climate change in the study area.

## Covered Activities and Climate Change

The Plan will provide endangered species permits to development in the study area. Accordingly, the covered activities may contribute to climate change by allowing increased emissions that result from urban expansion and vegetation removal. The covered activities listed below are expected to have the greatest potential effect on GHG emissions.

- **Urban Development.** All projects related to urban growth within designated urban areas. This covered activity will facilitate population growth in the study area and will likely result in increased motorized vehicle use, which in turn contributes to climate change. Increased energy use driven by population growth is also predicted.
- **Rural Capital Projects.** Projects related to new road construction in rural areas. As with urban development, any project that facilitates increased motorized vehicle use qualifies as a potentially significant contributor to climate change.
- **Rural Development.** Projects related to development outside designated urban areas. This covered activity will facilitate population growth in the study area, and will likely result in increased motorized vehicle use. Increased energy use driven by population growth is also predicted.

This impact analysis does not quantify the impacts from covered activities due to climate change. Predictions of how much covered activities will contribute to climate change cannot be made and it will be up to those projects to develop and implement their own mitigation for their future effects.

## Conclusions

The Plan will not be implemented independent of global climate change. The conservation strategy and Monitoring and Adaptive Management Program are designed to ensure that lands are acquired and managed in a way that preserves flexibility and increases resilience and that adverse impacts on the natural communities and covered species will be detected early. As the requirements of natural communities and species shift over time, the flexible nature of the plan and the perpetuity of funding will allow for management to occur throughout implementation and beyond the permit term. Accordingly, the Plan will change with the climate, ensuring species persistence to a much greater extent than would be afforded by other alternative approaches such as project-by-project mitigation.

## Personal Communication

Hillman, Janell M. Botanist. Santa Clara Valley Water District. San Jose, CA.  
December 12, 2007—email to Terah Donovan, Conservation Planner, Jones & Stokes, Oakland, CA.

**Table F-3.** Potential Climate Change Effects on Selected Covered Species

	Potential Climate Change Effects during Permit Term				
Species	Phenological Mismatch	Range and Distribution Shift	Change in Abundance	Morphology and Genetics	Rationale
<b>Butterflies</b>					
Bay checkerspot butterfly	X	X	X		Dependence on larval host plant presence restricts current range to serpentine soils with a suitable microclimate. Change in timing or intensity of seasonal event could have an effect on plant abundance and availability during the critical species reproductive period, as well as macro- and microclimatic suitability, leading to phenological mismatch and decrease in species abundance. Changes in microclimate suitability could further restrict species range and distribution.
<b>Amphibians</b>					
California red-legged frog	X	X	X		Life history and physical characteristics of amphibians make them dependent on climatic variables for reproductive success and species perseverance. Change in precipitation timing and quantity could change habitat availability during the breeding season, leading to a phenological mismatch, shift in range and distribution, or change in abundance. Increases in precipitation and lengthening of the rainy season could favor an increase in range and distribution and abundance. Decreases in precipitation and/or decreases in length or delayed timing of the rainy season could lead to phenological mismatches, range and distribution shifts, and decrease in abundance.
California tiger salamander	X	X	X		
Mountain yellow-legged frog	X	X	X		
<b>Reptiles</b>					
Western pond turtle			X	X	Turtles have exhibited temperature dependent sex-ratios. Temperature increases in the study area could result in skewed sex ratios, favoring females over males. An extreme decrease in males could lead to decreased abundance due to reduced mating frequency.
<b>Plants</b>					
Coyote ceanothus	X	X	X		Serpentine plant distribution is restricted to highly specialized and localized habitat requirements that include species-specific microclimate conditions coincident with serpentine soil occurrence. Restriction to serpentine soils limits species range and distribution to this soil type. Climate change could change microclimate conditions so that species can no longer persist within their current range. Increase in favorable microclimate conditions could lead to an expansion of distribution and increase in abundance, both in terms of number of populations and number of plants within each population. Change in timing or intensity of seasonal events could have an effect on
Santa Clara Valley dudleya	X	X	X		
Metcalf Canyon jewelflower	X	X	X		
Mount Hamilton thistle	X	X	X		
Smooth lessingia	X	X	X		

**Table F-3. Continued**

Species	Potential Climate Change Effects during Permit Term				Rationale
	Phenological Mismatch	Range and Distribution Shift	Change in Abundance	Morphology and Genetics	
Tiburon Indian paintbrush	X	X	X		pollinator reproductive and plant flowering periods leading to phenological mismatches.
Fragrant fritillary	X	X	X		
Loma Prieta hoita	X	X	X		
Most beautiful jewelflower	X	X	X

## **Cost Model**

Santa Clara Valley Habitat Plan  
Implementation Budget Data and Assumptions

Aug-2012

**Final Plan**

## **Santa Clara Valley Habitat Plan Implementation Budget**

### **G-0a Assumptions / Notes**

### **G-0b Acres acquired by location and size**

### **G-0c Acres restored - land cover**

### **G-0d Reserve area managed - land cover**

### **G-0e Reserve area monitored - species**

### **G-1 Program Administration**

- a. Reserve staff
- b. Office space
- c. Utility cost for office space
- d. Office furniture, equipment, and supplies
- e. General office equipment
- f. Technology equipment / services
- g. Passenger vehicles and fuel
- h. Vehicle mileage allowance
- i. Overnight travel
- j. Insurance
- k. Staff training
- l. Staff uniforms
- m. Legal assistance
- n. Financial analysis assistance
- o. JPA meeting stipends
- p. Law enforcement / Public safety
- q. Public education/outreach

### **G-2 Shared Staff and Overhead (allocated to management, restoration, and monitoring)**

- a. Reserve staff
- b. Office furniture, equipment, and supplies
- c. Passenger vehicles and fuel
- d. Vehicle mileage allowance
- e. Overnight travel

### **G-3 Land Acquisition**

- a. Land acquisition costs over 50 years
- b. Cost assumptions: fee title by location and parcel size
- c. Due diligence
- d. Pre-acquisition surveys
- e. Site improvements: demolition, road obliteration and stabilization/abandonment, fences, gates, signs

## **Santa Clara Valley Habitat Plan Implementation Budget**

### **G-4 Habitat Restoration / Creation**

- a. Land cover type restored / created
- b. Cost of restoration / creation construction (contractors and reserve staff)
  - Design
  - Plans and specifications
  - Bid assistance
  - Pre-construction surveys
  - Construction
  - Construction oversight & monitoring
  - Post-construction oversight and monitoring
  - Restoration repair
  - Contingency
- c. Environmental compliance for restoration projects (CWA 404/401, CDFG 1602)
- d. Reserve staff
- e. Office furniture, equipment, and supplies
- f. Passenger vehicles and fuel
- g. Vehicle mileage allowance
- h. Overnight travel
  - i. Long-term management on restored lands
  - j. Long-term biological monitoring on restored lands

### **G-5 Reserve Management and Maintenance**

- a. Reserve staff
- b. Office furniture, equipment, and supplies
- c. Overnight travel
- d. Passenger vehicles and fuel
- e. Vehicle mileage allowance
- f. Other vehicles, maintenance, and fuel
- g. Leased vehicles and equipment
- h. Special equipment and materials
  - i. Field facilities, including permanent seed bank
  - j. Maintenance and utilities for facilities
- k. Wells and water pumping
  - l. Invasive species control (reserve staff and contractors)
- m. Existing open space
- n. Contractors: management, maintenance, construction services for roads and bridges
- o. Environmental compliance for reserve management projects (NEPA/CEQA, NHPA)
- p. Remedial measures

## **Santa Clara Valley Habitat Plan Implementation Budget**

### **G-6 Monitoring, Research, and Scientific Review**

- a. Reserve staff
- b. Office furniture, equipment, and supplies
- c. Passenger vehicles and fuel
- d. Vehicle mileage allowance
- e. Overnight travel
- f. Biological monitoring by species and land cover (contractors)
- g. Natural communities biological monitoring (contractors)
- h. California Tiger Salamander breeding habitat (contractors)
- i. Enhanced monitoring on existing open space (contractors)
- j. Directed research
- k. Scientific review - Conservation Assessment Team and Science Advisors panel

### **G-7 Western Burrowing Owl Conservation Strategy**

- a. Grazing on managed land
- b. Equipment and tools cost, capital, operations, and annual maintenance
- c. Targeted studies - Baylands Region
- d. Monitoring of Western Burrowing Owl compensation sites (reserve system or other managed lands)
- e. Optional tasks, operational

### **G-8 Contingency Fund**

- General operating
- Land acquisition and site improvements

### **G-9 Post-permit Budget**

- a. Program administration
- b. Shared staff and overhead
- c. Reserve management and maintenance

## Legend

red numbers are assumptions or data entered directly into the worksheet

blue numbers are links from other worksheets in the workbook

black numbers are calculations based on the above numbers

Numbers provided by Santa Clara County Parks

Numbers provided by Santa Clara Valley Water District

Numbers provided by Santa Clara County Open Space Authority

Numbers provided by California Department of Parks & Recreation

Numbers provided by California Department of Fish & Game

Numbers provided by Valley Transportation Authority

Average of multiple sources

Numbers provided by ICF and HEG

Guesstimated numbers

Input tables/values pasted into budget model workbook

Indicates species or land cover for which management and monitoring costs are shifted upon restoration

Indicates input value or formula sensitive to time period, i.e., % of activity or number of acres per period/year

Indicates input value not yet available or placeholder value awaiting confirmation

Enter year for constant dollar values:

**2010 dollars**

Enter Plan Draft Status:

**Final Plan**

Enter Model Date:

**Aug-2012**

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-0a: Master list of assumptions used to develop Habitat Plan Implementation budget**

**G-1, G-2, and G-5 Staffing/Personnel Costs**

G-1a, G-2a, and G-5a: Salaries and Benefits, Travel

Salary per employee per year	Benefit multiplier (percent of salary)		G-2e: Days of overnight travel per FTE per year	G-2d: Mileage allowance per year per FTE (miles)	Number of FTEs, per year

50%	Admin-Secretary time allocated to program administration/public outreach
50%	Admin-Secretary time allocated to reserve management
\$186	Travel allowance per diem
3.00	Per diem multiplier for executive director to cover additional travel expenses such as airfare
\$0.514	Cost per mile for travel allowance

Assumes Administrative Director uses implementing entity-owned passenger car and field staff use owned trucks, see G-2c and G-5f

**Overhead cost allocation**

10%	Proportion of shared staff, equipment, vehicle, and travel costs allocated to program administration
35%	Proportion of shared staff, equipment, vehicle, and travel costs allocated to management
35%	Proportion of shared staff, equipment, vehicle, and travel costs allocated to restoration
20%	Proportion of shared staff, equipment, vehicle, and travel costs allocated to monitoring and research
100%	

**G-1, G-2, and G-5 Equipment and Vehicles**

**G-2b: Office Furniture and Equipment per employee**

Cost per FTE per replacement period	Cost of service contract per year	Equipment type	Replacement Period (years)
\$2,120		Common office furniture	20
\$2,120		Cubicle furniture	20
\$530		Office supplies (annual)	1
\$2,650	\$265	Computers	3
\$636	\$127	Cell phones	2
\$954	\$191	Mobile radios	3
2		unit of common office furniture purchased every 20 years	
1		Mobile radio per vehicle	

**G-1e: General Office Equipment**

Cost per year (leased items) / cost per item (purchased items)	Cost of service contract per item per year	Type of Equipment	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50
\$11,660	\$0	Color printer/copy machine/scanner (lease)	-	1	1	1	1	1	1	1	1	1	1
\$6,360	\$0	Office telephone systems (lease)	-	1	1	1	1	1	1	1	1	1	1
\$1,590		Books and journals (purchase)	-	5	5	5	5	5	5	5	5	5	5
\$265		New fax machines purchased	-	1	1	1	1	1	1	1	1	1	1
		Old fax machines retired	-	-	1	1	1	1	1	1	1	1	1
	\$0	Total fax machines	-	1	1	1	1	1	1	1	1	1	1
\$1,484		New printers purchased	-	2	2	2	2	2	2	2	2	2	2
		Old printers retired	-	1	1	2	2	2	2	2	2	2	2
	\$0	Total printers	-	1	2	2	2	2	2	2	2	2	2
\$514		New digital cameras purchased	-	4	4	4	4	4	4	4	4	4	4
		Old digital cameras retired	-	2	4	4	4	4	4	4	4	4	4
	\$0	Total digital cameras	-	2	2	2	2	2	2	2	2	2	2
\$2,650		Radio base station purchased	-	1	-	1	-	1	-	1	-	1	-
		Radio base station retired	-	-	-	1	-	1	-	1	-	1	-
	\$106	Total radio base stations	-	1	1	1	1	1	1	1	1	1	1
\$6,360		Trunked radio system (shared tower and repeaters)	-	1	1	1	1	1	1	1	1	1	1

Assumes printer and phone maintenance/service contracts provided at no cost by Permittees.

5	year replacement period for fax machine and printer.
3	year replacement period for digital cameras.
10	year replacement period for radio base station.

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-0a: Master list of assumptions used to develop Habitat Plan Implementation budget**

G-1f: Technology Equipment/Services			Number of items leased, purchased, or retired, by period											
Cost per item	Cost of software update or service contract per 5-year period	Type of Equipment	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50	
\$10,600		New GIS/database servers purchased	-	-	-	-	-	-	-	-	-	-	-	
	\$1,060	Old GIS/database servers retired	-	-	-	-	-	-	-	-	-	-	-	
		Total GIS/database servers	-	-	-	-	-	-	-	-	-	-	-	
\$5,300		New tablet PC purchased	-	2	2	2	2	2	2	2	2	2	2	
		Old tablet PCs retired	-	-	2	2	2	2	2	2	2	2	2	
	\$530	Total tablet PCs	-	2	2	2	2	2	2	2	2	2	2	
\$11,130		New plotters purchased	-	1	-	1	-	1	-	1	-	1	-	
		Old plotters retired	-	-	-	1	-	1	-	1	-	1	-	
	\$424	Total plotters	-	1	1	1	1	1	1	1	1	1	1	
\$4,240		New GPS units purchased	-	2	2	2	2	2	2	2	2	2	2	
		Old GPS units retired	-	-	2	2	2	2	2	2	2	2	2	
	\$742	Total GPS units	-	2	2	2	2	2	2	2	2	2	2

		Old GIS software retired	-	-	-	-	-	-	-	-	-	-	-	
	\$1,590	Total GIS software	-	-	-	-	-	-	-	-	-	-	-	
\$3,180		New computer software purchased	-	2	2	2	2	2	2	2	2	2	2	
		Old computer software retired	-	-	2	2	2	2	2	2	2	2	2	
	\$742	Total computer software	-	2	2	2	2	2	2	2	2	2	2	
\$31,800		annual cost of contract GIS services, years 1 - 25												
\$21,200		annual cost of contract GIS services, years 26 - 50												
5		year replacement period for GIS and database equipment purchased.												
3		year software upgrade cycle												

**Assumptions/Notes:**

GIS services contracted with local partners or other entities.

**G-2c and G-5f: Passenger Vehicles and Fuel**

G-2c and G-5f: Passenger Vehicles and Fuel				Number of vehicle purchased, or retired											
Purchase price per vehicle	Fuel cost per vehicle per year		Maintenance cost per vehicle per year	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50	
\$21,624		New passenger cars purchased, per period	\$1,248	-	1	-	2	-	2	-	2	-	2	-	
		Old passenger cars retired, per period		-	-	-	2	-	2	-	2	-	2	-	
	\$1,590	Total passenger cars, per year, per period		-	1	1	1	1	1	1	1	1	1	1	
\$31,800		New 4WD trucks purchased, per period	\$2,080	-	2	2	3	3	3	3	3	3	3	3	
		Old 4WD trucks retired, per period		-	-	2	3	3	3	3	3	3	3	3	
	\$2,120	Total 4WD trucks, per year, per period		-	2	2	2	2	2	2	2	2	2	2	
\$8,480		New ATVs and trailers purchased, per period	\$520	-	1	1	2	1	2	1	2	-	1	1	
		Old ATVs and trailers retired, per period		-	-	1	1	2	1	2	1	2	-	1	
	\$424	Total ATVs and trailers, per year, per period		-	1	1	2	2	2	2	2	1	1	1	
		Total vehicles		-	4	4	5	5	5	5	5	4	4	4	

**G-5g: Leased Vehicle/Equipment**

Daily Lease Cost	Average days of use per 1,000 acres per year	Type of Vehicle / Equipment
\$244	2	Tractor
\$138	2	Small tractor
\$207	2	Dump truck
\$104	2	Fire truck

**G-1 Other Program Administration**

**G-1b: Office Space**

Assumes Implementing Entity will lease office space.

2,000	Total space leased per period (square feet)
\$2.12	Cost per square foot per month, including utilities

**G-1c: Utility Costs**

Utility costs included in office lease costs, above.

\$0.00	Annual cost per sq. ft. of office space
--------	---

**G-1j: Insurance**

\$1,858	Automobile insurance cost per year per vehicle
\$5,830	Directors' and officers' insurance cost per year
\$5,830	General liability insurance cost per year
\$8,745	Professional liability insurance cost per year

**G-1k: Staff Training**

\$318	Annual cost of training per staff member (excluding travel)
-------	---

**G-1l: Uniforms**

\$0	Annual cost for t-shirts and polos for all employees
-----	--

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-0a: Master list of assumptions used to develop Habitat Plan Implementation budget**

**G-1m: Legal Assistance**

Assumes outside legal counsel or cost of in-house counsel shared from a partner agency, particularly after start-up period.

		Hours of legal assistance per period - start-up
1,000		Hours of legal assistance per subsequent 5-year period
\$371		Hourly rate for legal assistance

**G-1n: Financial Analysis Assistance**

Assumes periodic financial assessments performed by outside contractors.

3		Year interval between financial analyses
\$37,100		Cost of Financial Analysis per three-year period

**G-1o: JPA Member Meeting Stipend**

8		Number of JPA members
\$318		Stipend per meeting per member
-		Number of meetings per year at start-up
20		Number of meetings per period years 1-5
20		Number of meetings per period years 6-10 and 11-15
10		Number of meetings per five-year period years thereafter

**G-1p: Law Enforcement / Public Safety**

Law enforcement and public safety costs on existing open space will be covered by County Parks through County Parks Rangers and the County Sheriff.

\$8.48		Law enforcement cost per reserve acre per year
--------	--	--

**G-1q: Public Education / Outreach**

Covers costs for material used during implementation such as brochures, fliers, meeting handouts, and posters. Includes costs for design and layout and printing.

\$0		Annual cost at start-up
\$53,000		Annual cost after start-up

**G-3 Land Acquisition**

**G-3a: Land Cover Type Acquired by Time Period**

Easements assumed for agricultural land and ranchland per the assumptions below.

300		Number of acres acquired in Remote West Hills during plan development ( <b>one</b> transaction, fee title).
200		Number of acres acquired in Near East Hills during plan development ( <b>one</b> transaction).
11%		Percent of each land cover type acquired in each 5-year period beginning in year 1, assuming acquisition complete by year 45, and acres acquired during plan development deducted from first period.
0%		Percent of Valley Floor that is agricultural land in the Pajaro River Valley that will be acquired using conservation easements
50%		Percent of Remote and Near Hills that is ranchland that will be acquired using conservation easements.
80%		Percent of fee title cost required for easement acquisition
3%		Contingency factor for land acquisition and site improvements

**G-3b: Proposed Land Acquisition Cost Assumptions, by location and parcel size (fee title purchase price per acre in 2010 dollars)**

Location	Less than 50 acres	50 - 250 acres	Over 250 acres
Near East Hills	\$28,000	\$9,000	\$8,000
Near West Hills	\$28,000	\$9,000	\$8,000
Remote East Hills	\$10,000	\$9,000	\$6,000
Remote West Hills	\$10,000	\$9,000	\$6,000
Almaden Valley / Valley Floor	\$34,000	\$17,000	\$16,000

For cost estimating purposes, land costs assumed to remain constant (in real terms) over time. See Chapter 9 for automatic and periodic inflation factors that are built into the fees to account for expected increases in land cost over time.

**G-3c: Due Diligence**

170		Number of acquisitions over plan term, including acquisitions during plan development (below)
2		Number of acquisitions during plan development.
1.25		Due diligence premium for land not acquired but surveyed/processed for potential acquisition. Applies to number of acquisitions and amount of land surveyed.
\$5,300		Appraisal cost per acquisition
\$530		Preliminary title report cost per acquisition
\$3,445		Phase 1 site assessment cost per acquisition
\$4,348		Legal description cost per acquisition
12,500		Average acquisition parcel boundary length in feet
\$0.48		Cost per linear foot for boundary survey
\$0.37		Cost per linear foot for monumentation

**G-3d: Pre-acquisition surveys - contractor hours**

12		Average hours per 100 acres for land cover type surveys including report writing
16		Average hours per 100 acres for covered species habitat surveys including report writing
32		Average hours per 100 acres for covered plant surveys including report writing
28		Average hours per 100 acres for covered wildlife surveys including report writing
100		Acres average/minimum parcel size for pre-acquisition surveys

Notes:

Land cover type surveys include surveys for federal and state jurisdictional waters, and submitting of a report to the USACE and obtaining a verification (includes some hours to respond to any changes the Corps may require). Land cover type and wetland delineation surveys will occur concurrently. Covered plant surveys include three visits during the blooming season to cover different blooming times.

Hours include field work and report writing.

**G-3e: Site Improvements**

Site improvements for land acquired during plan development assumed to occur during years 1 -5 of plan implementation.

Road and fencing improvements will facilitate grazing operations for ongoing landscape management.

\$5,300		Demolition of old facilities per 500 acres
\$4,240		Repair and replacement of gates per 100 acres
\$2,650		Signs (boundary, landbank, etc.) per 100 acres
\$2,120		Other security (e.g., boarding up barns) per 100 acres
\$11.66		Average cost of new fence installation by linear foot, once land is acquired
\$4.24		Average cost per linear foot for boundary fence repair or removal upon acquisition
27,800		Average linear feet of new fencing installed upon acquisition per 5-year time period; function of acquisitions over time
12,500		Average linear feet of existing fencing per acquisition
35%		Proportion of existing boundary fence that needs repair or removal at acquisition
\$106,000		Average cost per mile for road obliteration upon acquisition (re-contouring to natural contours, compaction, erosion control, seeding with natives and weed control)
0.25		Average miles of road obliterated upon acquisition per 1,000 acres acquired
\$21,200		Average cost per mile for road stabilization and abandonment upon acquisition (erosion control measures, removal of stream crossing reasures, ripping roadbed, etc.)
0.5		Average miles of road stabilization and abandonment upon acquisition per 1,000 acres acquired

Note: an additional 0.5 miles of road per 1,000 acres of Reserve System are assumed to be removed by simply closing off access and not doing any obliteration or erosion control work. No costs are assumed for this action.

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-0a: Master list of assumptions used to develop Habitat Plan Implementation budget**

## G-4 Habitat Restoration / Creation

### G-4a: Land Cover Type Restored / Created by Time Period

12.50%	Percent of each land cover type restored in each 5-year period beginning in year 1 through year 40, assuming all restoration completed by year 40
5	Width of stream (in feet) used to calculate total acres restored

### G-4b: Estimated cost per acre or linear foot of restoration by land cover type

#### Notes:

All restoration projects implemented by year 40.

Reserve staff would prepare restoration management plans.

Restoration planning, design, and implementation will be accomplished through a combination of contractors with staff oversight and management.

Plan, specification, and engineering work, bid assistance, and construction oversight are accounted for in the 5-year period in which construction takes place.

Five years of post-construction maintenance will be conducted in the 5-year period after construction takes place.

Post-construction restoration monitoring and maintenance is a 5-year period of staff monitoring and contractor remediation to ensure successful implementation of plan drawings,

including plant replacement, irrigation maintenance, weed control, erosion control, and repair of any substandard work.

	Willow and mixed riparian forest, scrub, and woodland	Central California sycamore alluvial woodland	Coastal and Valley Freshwater marsh	Seasonal wetlands	Ponds	Stream
Unit	Acre	Acre	Acre	Acre	Acre	Linear Ft.
Cost Category						
Design	\$1,060	\$1,060	\$1,060	\$1,060	\$1,060	\$5
Plans, specifications, and engineering	\$10,600	\$9,275	\$12,720	\$14,310	\$13,250	\$69
Bid assistance	\$212	\$212	\$318	\$318	\$318	\$1
Pre-construction surveys	\$390	\$390	\$104	\$104	\$104	n/a
Construction	\$42,400	\$37,100	\$63,600	\$71,550	\$53,000	\$276
Construction oversight & monitoring	\$2,120	\$1,855	\$3,180	\$3,578	\$2,650	\$14
Post-construction monitoring & maintenance	\$12,720	\$11,130	\$9,540	\$10,733	\$7,950	\$41
Restoration repair	\$6,360	\$5,565	\$9,540	\$10,733	\$7,950	\$41
<b>Total per acre cost</b>	<b>\$75,862</b>	<b>\$66,587</b>	<b>\$100,062</b>	<b>\$112,385</b>	<b>\$86,282</b>	
<b>Total per linear ft cost</b>						<b>\$447</b>
<b>Restoration contingency</b>	<b>\$11,379</b>	<b>\$9,988</b>	<b>\$15,009</b>	<b>\$16,858</b>	<b>\$12,942</b>	<b>\$67</b>

#### Other Assumptions:

25%	Plans, specifications, and engineering as percent of construction cost for non-aquatic restoration
20%	Plans, specifications, and engineering as percent of construction cost for marsh and seasonal wetland restoration
5%	Construction oversight and monitoring as percent of construction cost
30%	Post-construction monitoring and maintenance as percent of construction cost for woodland and riparian
19%	Post-construction monitoring as percent of construction cost for aquatic and wetland
19%	Percent of construction costs needed for restoration repair
19%	Contingency factor for restoration/creation; assumed to be higher than standard contingency
\$0	Ogier Ponds restoration project cost expected in years 6 - 10
0%	Percent of Ogier Ponds restoration project cost allocated to SCV HCP/NCCP
0.0	Miles of stream restored in Ogier Ponds project, expected in years 6-10

### G-4c: Environmental Compliance for Restoration Projects

Number of Projects Requiring Compliance Actions	Project size	Cost per project size and compliance category		
		CWA 404/401	CDFG 1602	Other
70	Small/simple	\$5,300	\$2,650	\$10,600
35	Medium/more complex	\$10,600	\$4,240	\$10,600
7	Large/most complex	\$26,500	\$8,480	\$10,600
12.50%	Percentage of projects requiring compliance in each 5-year period between years 1 and 40; linked to restoration over time			

## G-5 Management and Maintenance

### G-5h: Reserve Management Equipment, Materials, and Data

\$3,180	Capital cost of other equipment (e.g., hand-held tools and machines) and non-liquid materials (e.g., road gravel) per 1,000 reserve acres per year
\$530	Operational cost of equipment per 1,000 reserve acres per year
\$3,710	Cost per period to acquire aerial photos every 5 years to re-map land cover. Labor provided by Implementing Entity staff.

#### Notes:

Capital costs include the capital component of fire fighting equipment/gear, small tools (pliers, wrenches, screwdrivers, etc.), glasses, gloves, hard hats, rain gear, irrigation supplies, cargo container, landscape plants and grass, oak trees, lumber, and truck hauling services.

Operational costs include the operational component of fire fighting equipment/gear, small tools (pliers, wrenches, screwdrivers, etc.), glasses, gloves, hard hats, rain gear, irrigation supplies, cargo container, landscape plants and grass, oak trees, lumber, and truck hauling services.

Operational costs also include portable radios, small pumps, piping, generator, saw, and demolition hammers.

Grazing is assumed to be an important tool in landscape management on ranchland under conservation easements or grazing leases.

### G-5i: Field Facilities

10,000	Threshold for acres of reserve served by each workshop/parking area
\$530,000	Cost to build a workshop/parking area
\$0	Cost to build native plant nursery (\$75,000)
\$795	Cost of pre-construction surveys per project
5%	Construction oversight and monitoring as percent of construction cost
\$63,600	One-time cost to establish permanent seed bank collection

Note: Field facilities contain an area for equipment storage, a manager's office, a shared office, a locker room, restrooms, and a parking area.

Native plant nursery facilities assumed shared with other land management entities.

The seed bank collection will be established at the Rancho Santa Ana Botanic Gardens (or similar institution). Costs account for seed bank collection design, collection time by consultants or Implementing Entity staff,

seed banking fees at the storage institution, and miscellaneous expenses.

Six covered plant species would be established at the permanent seed bank: Santa Clara Valley dudleya, coyote ceanothus, most beautiful jewel-flower, Metcalf Canyon jewel-flower, smooth lessingia, and Mt. Hamilton thistle.

Seed bank established during years 1 - 5.

### G-5j: Facilities Maintenance and Utilities

\$10,600	Maintenance cost per facility per year
\$2,650	Utilities cost per field facility per year
\$0	Annual operating cost for native plant nursery

### G-5k: Wells and Water Pumping

0.5	Number of wells per 1,000 acres
\$31,800	Cost to drill a well
\$15,900	Cost of pump and related equipment
\$265	Annual cost to operate pump per well/pump.

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-0a: Master list of assumptions used to develop Habitat Plan Implementation budget**

G-5f: Invasive Species Control

Management activities for invasive species by land cover

Land Cover Type	Application of herbicides	Prescribed burns	Average proportion of land cover burned per year (%)	Acres managed with prescribed burns (total in year 50)	Feral pig management	Brown-headed Cowbird	Grazing
California Annual Grassland	x	x	5.0%	665.0	x		x
Serpentine Bunchgrass Grassland		x	10.0%	400.0	x		x
Serpentine Rock Outcrop / Barren							
Serpentine Seep					x		
Rock Outcrop					x		
Northern Mixed Chaparral / Chamise Chaparral							
Mixed Serpentine Chaparral							
Northern Coastal Scrub / Diablan Sage Scrub		x	2.5%	35.0	x		x
Valley Oak Woodland	x	x	5.0%	85.0	x		x
Mixed Oak Woodland and Forest					x		x
Blue Oak Woodland	x	x	5.0%	55.0	x		x
Coast Live Oak Forest and Woodland					x		x
Foothill Pine - Oak Woodland		x	2.0%	1.6	x		x
Mixed Evergreen Forest					x		
Willow Riparian Forest and Scrub						x	x
Central California Sycamore Alluvial Woodland					x		x
Mixed Riparian Forest and Woodland					x	x	x
Redwood Forest						x	x
Ponderosa Pine Woodland		x	1.0%	0.0	x		x
Knobcone Pine Woodland		x	3.0%	0.0	x		x
Coastal and Valley Freshwater Marsh							x
Seasonal Wetland					x		
Pond							x
Streams (miles)							
<b>Total</b>				<b>1,241.6</b>			

\$530 Cost of weed management supplies (not labor) per 1,000 acres of reserve per year, for hand spraying. Applies to all reserve acres

\$27 Cost of applications of herbicides per period per acre managed

\$48 Cost of prescribed burns per acre burned

\$1,325 Cost of feral pig management per year per 1,000 acres managed

\$32 Cost to control brown-headed cowbird per year per acre managed. Would occur periodically in strategic locations throughout the reserve system.

Note: Bullfrog management activities will be conducted by reserve staff. All herbicides applied according to label instructions. Pesticides may be applied using aerial, truck, or hand application.

Grazing will be used as applicable for weed management in lieu of herbicides and prescribed burns. Some rangeland may be leased for grazing and some ranchland acquired with conservation easements will be grazed.

Management activities for control of non-native fish

177 Acres of ponds acquired and restored in reserve system, at end of plan term.

0.5 Acres per pond (Table 5-12)

30% Percent of ponds managed for control of non-native fish

0.5 Number of management activities (applications) per pond per year to control non-native fish assuming management occurs every other year.

\$106 Cost to control non-native fish per pond per application (supplies only, not labor).

Note: Management activities for non-native fish will be done by reserve staff. Costs for management for non-native fish in ponds in existing open space covered in Table G-5m.

Invasive species control on restored wetlands covered as a restoration cost.

G-5m: Management activities on existing open space

Acres of existing County Parks that will be managed for the Habitat Plan	Almaden Quicksilver County Park	Anderson Lake County Park	Calero County Park	Coyote Lake-Harvey Bear Ranch County Park	Joseph D. Grant County Park	Mt. Madonna County Park	Santa Teresa County Park	Uvas Canyon County Park	Total
Total Managed Acres (Table 5-5)	653	486	1,690	825	7,760		877		12,291
Average annual species and natural community management cost per acre	\$95	\$80	\$64	\$95	\$53	\$42	\$95	\$42	
Annual management cost for existing open space unit	\$62,296	\$38,637	\$107,484	\$78,705	\$411,280	\$0	\$83,666	\$0	\$782,068

Management activities begin in year 6.

Does not include other costs such as recreation and law enforcement / public safety because those services are already provided by County Parks and the County Sheriff.

Acres of existing Open Space Authority lands that will be managed for the Habitat Plan (Table 5-5)	1,000
Average annual species and natural community management cost per acre	\$95
Annual management cost for existing open space	\$95,400

Management activities begin in year 6.

G-5n: Contractors - for on-going management and maintenance

\$106,000	Reserve unit management plans: One for each of five reserve units. Cost per initial plan. First 3 written in first five years and another 2 written in second five years.
\$21,200	Cost to update reserve unit management plan once every 5 years.
\$1,590	Cost for pond maintenance (dredging) per acre of pond every 5 years
\$1,060	Cost of dirt (ranch) road maintenance per mile of road per year
0.75	Miles of dirt (ranch) road constructed, per 1,000 acres acquired
\$2,650	Cost for other maintenance services per 1,000 acres of reserve per year

Costs for Neighboring Landowner Agreement baseline and land cover surveys would be incurred by the landowner.

Other maintenance services include mowing, grading, pest control, diskling for fire breaks, fencing, alarms, janitorial services, removing debris associated with illegal marijuana cultivation.

Pond maintenance services on restored ponds covered as a restoration cost.

G-5n: Contractors - capital costs for construction services including bridge and roadway design, paving, fencing, grading, and boundary surveying services

\$84,800	Cost for paved road construction per mile
\$42,400	Cost for dirt (ranch) road construction per mile
-	Miles of paved road constructed, per 1,000 acres acquired
0.75	Miles of dirt (ranch) road constructed, per 1,000 acres acquired
0.5	Number of vehicle bridges installed per period
\$636,000	Cost per vehicle bridge to install
	Number of trail bridges installed per period
\$22,260	Cost per trail bridge to install
\$795	Cost of pre-construction surveys (per year for road construction and per project for bridge installation)
5%	Construction oversight and monitoring as percent of construction cost
\$0	Seed money to implement recommendations of feasibility study regarding wildlife linkages (originally \$1,500,000)

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-0a: Master list of assumptions used to develop Habitat Plan Implementation budget**

G-5o: Environmental Compliance for Reserve Management Projects

Number of Projects Requiring Compliance Actions	Project size	Cost per project size and compliance category	
		NEPA/CEQA	NHPA
70	Small/simple	\$5,300	\$2,650
35	Medium/more complex	\$42,400	\$3,710
7	Large/most complex	\$106,000	\$9,010
12.50%	Percentage of projects requiring compliance in each 5-year period between years 1 and 40; linked to restoration over time		

G-5p: Remedial Measures

10%	Percent of reserve management and maintenance operational cost assumed to be needed for remedial actions on reserve lands.
-----	--

Notes:

Applies to operational budget for management activities on reserve lands.

Applies to western burrowing owl conservation strategy management costs from Table G-7.

Management costs include overall reserve management.

Covers costs associated with responses to adaptive management findings as well as costs for restoration or maintenance of reserve areas in response to other changed circumstances such as wildfire or drought.

Remedial measures for restoration activities are included as a restoration cost.

## G-6 Monitoring, Research, and Scientific Review

Notes:

Compliance monitoring for implementation will be conducted by program administration staff and is addressed under the program administration cost category.

General landscape level surveying and monitoring will be done by staff, once every 5 years.

Pre-acquisition survey costs are covered under the land acquisition cost category.

Monitoring on restored/created wetlands is addressed under the restoration cost category.

Pre-construction surveys are assumed to occur prior to construction of covered activities on the reserve system, and costs are estimated as a component of those restoration and management costs.

Construction monitoring is assumed to occur periodically during construction of covered activities and conservation measures, and costs are estimated as a component of those restoration and management costs.

Implementing entity monitoring staff will plan, coordinate, and report on the monitoring categories described below.

Contractors will conduct the field monitoring and data analysis.

Pre-acquisition, pre-construction surveys, and construction monitoring for covered activities outside of the reserve system will be paid for by developers.

\$265,000 Cost to develop a monitoring plan during the first 5 yrs of implementation (e.g., to develop monitoring protocol, success criteria, etc.)

\$53,000 Cost to update monitoring plan every 10 years. These costs would be supplemented by the ongoing work of the science advisors.

G-6f: Biological monitoring contractor hours per year by species and land cover for complete reserve system (covers Validation and Status & Trends Monitoring)

Species	Unit	Habitat Type that is monitored annually	Habitat added to Reserve System that is Monitored (Table 5-17) or Occurrence (Table 5-16)	Number of monitoring days per year (complete reserve system) Do not change, originally derived from Alt 2 (8/2007). Adjust calculated factor instead.	Number of contractors per visit (complete reserve system) Do not change, originally derived from Alt 2 (8/2007).	Total person hours per year (8 hour days) - Function of acres monitored and calculated ratio from Alt 2 (8/2007) intensive monitoring here.	Acres or miles per hour per year (calculated from Alt 2, 8/2007) Used as constant so that total person-hrs are a function of acres monitored. Adjust for less intensive monitoring here.	Cost Factor for Cost Worksheet: Annual cost for monitoring, complete reserve system
California Red-Legged Frog	acres	Primary (Breeding)	1,300	40	2	569	2.29	\$72,281
California Red-Legged Frog - streams	miles	Primary (Breeding)	n/a	5	2	-	n/a	\$0
California Tiger Salamander	acres	Breeding	150	30	2	493	0.30	\$62,680
Pond Turtle	acres	Primary (Breeding)	7,000	10	2	115	61.08	\$14,567
Pond Turtle (streams)	miles	Primary (Breeding)	n/a	5	2	-	n/a	\$0

Bay checkerspot butterfly	acres	Primary (Breeding)	3,800	40	4	1,248	3.04	\$158,639
Total				295		3,373		
Total annual cost (rounded)						\$430,000		\$430,000

Notes

Monitoring focus is on ponds and wetlands

Monitoring focus is on ponds

Pond turtle surveys conducted mostly at same time as CRLF surveys

Pond turtle surveys in streams overlap with Foothill yellow-legged frog surveys

See G-7 Western Burrowing Owl

See G-7 Western Burrowing Owl

Surveys of buildings and other structures

Intensive surveys in breeding season

Intensive surveys in breeding season

Spot surveys of possible nest sites throughout the year

Intensive surveys in spring and early summer

G-6g: Natural communities biological monitoring contractor hours per year by land cover for complete reserve system (covers Validation and Status & Trends Monitoring)

Natural Communities	Unit	Natural Community added to Reserve System that is Monitored (Table 5-13)	Number of monitoring days per year (complete reserve system)	Total person hours per year (8 hour days) for 45,000 acre complete reserve system	Total person hours per year (8 hour days) - Function of acres monitored and calculated ratio for 45,000 acre reserve	Acres per hour per year (calculated for 45,000 acre reserve) Used as constant so that total annual person-hrs is a function of acres monitored	Cost Factor for Cost Worksheet: Annual cost for monitoring, complete reserve system
Grassland	acres		17,440	30	226	77.29	\$28,679
Chaparral & Northern Coastal Scrub	acres		2,500	2	16	223.13	\$1,424

Total			34,153		768	598	\$107,710

Notes

includes monitoring for California Ground Squirrel

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-0a: Master list of assumptions used to develop Habitat Plan Implementation budget**

<b>G-6f: Covered plant surveys</b>	
199	Total covered plant occurrences protected, including the occurrences on existing open space, number protected by the Plan and the number created
9	Hours of covered plant surveying per occurrence per year
<b>G-6f: Townsend's Bat Maternity Colonies</b>	
\$0	Annual cost to monitor Townsend's bat maternity colonies
<b>G-6f: Species and Land Cover Type Added to Monitoring Base per year</b>	
2.2%	Percent of each species and/or land cover added each year beginning in year 1, assuming 45-year acquisition period.
<b>G-6f and G-6g: Cost Premium for Monitoring in First 10 years</b>	
15%	Percent premium on costs in years 1 - 10 to reflect more intensive early efforts and the fact that monitoring would become more efficient over time.
<b>G-6f: Biological monitoring contractors - hourly cost</b>	
\$101	Base cost per hour, Bay Area ES-II billing rate
\$198	Per diem including lodging (\$ per day)
\$26	Travel (\$ per day)
\$0	Miles assumed for travel
\$0.514	Dollars per mile for travel
8	Hours per day
\$127	Contractor cost per hour including amortized per diem and travel

**Table G-6h: California Tiger Salamander: Management plan, baseline genetic study, and on-going genetic monitoring for hybridization**

The objective of the management plan and baseline genetic study is to determine the percent of non-native genes in occupied sites (ponds/wetlands) and develop a management plan based on the data. The objectives of the on-going monitoring are to inform the adaptive management process associated with the Management Plan, evaluate effectiveness of management/restoration, and inform decision-making regarding CTS habitat restoration/acquisition.

<b>Assumptions / Notes:</b>	
215	total acres of CTS breeding habitat monitored by year 45, includes acquired reserve land and existing open space (Table 5-17)
	Year 15 Year 30 Year 45
Reserve system commitment by time period (Table 5-14)	30% 70% 100%
CTS breeding habitat (acres) acquired by time period, cumulative	65 151 215

Baseline study data collection will occur during the first 15 years of plan implementation due to the relatively low number of ponds/wetlands within the Reserve System at the onset of the permit.

Breeding habitat is added relatively evenly over time, and hybridization is only monitored within Reserve System lands.

If a habitat is occupied, genetic samples will be collected and that habitat will be sampled again every three years.

Three years of sampling are required to determine habitat as unoccupied.

Two people (Project Leader/Permitted Specialist and Senior Field Crew) are required for each potential breeding habitat site visit.

A field season includes time for the following activities: personnel management, project planning, data collection, data entry and management, and report writing.

30%	Percent of potential breeding habitat that is occupied habitat and therefore re-visited every three years for tissue collection purposes
20	Number of samples collected per occupied site
2	Number of pond/wetland sites visited per day, first 5 years
2.5	Number of sites visited per day, beginning in year 6
5	Days per year for project-related duties for Project Leader and for Senior Field Crew
\$140	Project Leader / Permitted Specialist, hourly rate
\$100	Senior Field Crew, hourly rate
\$150	Cost per sample for genetic testing, lab component
\$3,500	Annual cost for genetic testing: analysis and method design
\$3,500	Cost per period for collection equipment (waders, dip nets, buckets, etc.) years 1 - 5
\$2,500	Cost per period for collection equipment (waders, dip nets, buckets, etc.) years 6 - 15
\$3,500	Cost per period for tissue sampling equipment (collection jars, clippers, labels, notebooks, etc.) years 1 - 5
\$2,500	Cost per period for tissue sampling equipment (collection jars, clippers, labels, notebooks, etc.) years 6 - 15
15%	Percent of all occupied sites visited annually.
\$300	Annual cost for collection equipment (waders, nets, dip nets, buckets, etc.)
\$300	Annual cost for tissue sampling equipment (collection jars, clippers, labels, notebooks, etc.)

## Assumptions:

New potential breeding habitat acreage will continue to be added to the Reserve, so baseline monitoring will continue to determine occupancy and percent non-native gene frequencies.

Ponds/wetlands will be acquired/restored as part of the Conservation Plan, adding additional monitoring needs.

Representative ponds/wetlands will continue to be monitored at about the same frequency as with the hybridization/population monitoring.

All occupied sites will be visited and sampled on a regular basis, as stipulated by the Management Plan. For the purpose of this model, it is assumed occupied sites will be revisited every 5 years.

**G-6i: Monitoring enhancement for existing open space (County Parks and Open Space Authority lands)**

30%	percent of monitoring cost per acre required for monitoring enhancement of existing open space
-----	--

Monitoring activities begin in year 3

<b>G-6j: Directed Research</b>		Average annual funding required for directed research, per period.									
		0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45
		\$0	\$79,500	\$79,500	\$53,000	\$21,200	\$21,200	\$0	\$0	\$0	\$0
\$530,000	Directed research in Period 1-5 to investigate the feasibility of improving wildlife movement (Metcalf Canyon and Coyote Crk to Tulare Hill; Pajaro River between Santa Cruz Mts and Diablo Range; across Hwy 152 along Pacheco Creek.										

**G-6k: Scientific Review**

5	Members of Independent Conservation Assessment Team
\$5,300	Stipend per member per 5-year period
8	Members of Science Advisors panel
\$8,480	Stipend per member per 5-year period

## Notes:

Adaptive management experiments are covered under the monitoring staff and directed research categories.

Independent Conservation Assessment Team meets once every 4 years.

## G-7 Western Burrowing Owl Conservation Strategy

Management and monitoring costs for the Western Burrowing Owl conservation strategy were a late addition to the habitat plan.

Costs and detailed assumptions are shown on a separate sheet in the model--G-7.

Costs are summarized as a separate line item and are not integrated with other management and monitoring costs.

See Tables G-7a - e on G-7 Western Burrowing Owl sheet for detailed assumptions and notes.

## G-8 Contingency Fund (not including restoration contingency)

3%	Percent of total program funding, exclusive of acquisition capital budget and restoration budget, needed for contingency fund.
3%	Contingency factor for land acquisition (applied to land acquisition capital costs, including site improvements).

Western Burrowing Owl Conservation Strategy	\$226,009	\$0
Habitat Restoration/Creation: vehicle maintenance and personnel	\$0	\$0
Program Administration: personnel, legal and financial assistance, insurance, ED's discretionary budget, in-lieu funding	\$639,478	\$0
Operating Contingency Fund	\$0	\$0
<b>Total</b>	<b>\$2,739,297</b>	<b>\$63,194</b>
Land Acquired and Managed for Reserve System	34,153	
Existing Open Space Managed for Reserve System	13,291	
<b>Total Acres Managed / Wetlands Restored</b>	<b>47,444</b>	<b>506.3</b>
<b>Average Annual Cost per Acre Managed, New Reserve System</b>	<b>\$50</b>	<b>\$120</b>
<b>Average Annual Cost per Acre Managed, Existing Open Space</b>	<b>\$70</b>	

Notes / Comments:

Acquisition complete by year 45.  
Replacement period doubled. No other capital costs post-permit.

Restoration complete in year 45.  
Replacement period doubled.  
Not required post-permit.

Acquisition complete by year 45.  
Reserve planning at 50% of annual cost in year 50. Other reserve management at 100% of annual cost in year 50. Includes cost to manage land acquired for the Reserve as well as existing open space.  
Includes monitoring on land acquired for the Reserve as well as on existing open space.

Restoration complete by year 45.  
Public education and outreach at 50% of annual cost in year 50. Other administration at reduced staffing plus 100 percent of per employee cost. Equipment and furniture replacement period and upgrade cycle doubled.  
Not required post-permit.

## Capital Budget through Year 50, by Category, Santa Clara Valley Habitat Plan - Final

Land Acquisition Management and Monitoring Habitat Restoration/Creation Contingency Fund

App\_G-1\_BudgetModel\_2010-dollars\_August 2012 FINAL

## Annual Average Operating Budget by Category, Selected Implementation Periods, Santa Clara Valley Habitat Plan - Final

App\_G-1\_BudgetModel\_2010-dollars\_August 2012 FINAL

## Average Annual Cost per Acre Managed, by Implementation Period, Santa Clara Valley Habitat Plan - Final

App\_G-1\_BudgetModel\_2010-dollars\_August 2012 FINAL

## Reserve Acres by Location, Santa Clara Valley Habitat Plan - Final

App\_G-1\_BudgetModel\_2010-dollars\_August 2012 FINAL

**Table G-0b: Reserve Area Acquired (input by location and parcel size from SCV Habitat Plan database)**  
**Final Plan**

Location	Acres by location and parcel size				Percent of Total by Location	Easements (acres)
	Less than 50 acres	50 - 250 acres	Over 250 acres	Total		
Near East Hills	300	2,290	6,180	8,770	24%	4,385
Near West Hills	270	640	2,850	3,760	10%	1,880
Remote East Hills	20	1,920	9,740	11,680	32%	5,840
Remote West Hills	10	820	9,350	10,180	28%	5,090
Almaden Valley/Valley Floor	80	390	1,240	1,710	5%	-
<b>Total</b>	<b>680</b>	<b>6,060</b>	<b>29,360</b>	<b>36,100</b>	<b>100%</b>	na
<b>Percent of Total by Parcel Size</b>	<b>2%</b>	<b>17%</b>	<b>81%</b>	<b>100%</b>		<b>17,195</b>
percent of total acquisition						48%

Assumptions / Notes:

The number of acres acquired is greater than the Reserve Area Managed (Table G-0d) because the Plan also includes requirements (e.g., connectivity, protection of plant occurrences) that will result in additional acquisitions and because parcels purchased to meet a specific requirement will include additional acres of non-target land cover types.

# Santa Clara Valley Habitat Plan Implementation Budget

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-0d: Reserve Area Acquired and Managed by Land Cover Type (Source: Table 5-13)**

## Final Plan

Land Cover Type (acres except where noted)	Unit	Acquired and Managed (input value)
California Annual Grassland	acres	13,300
Serpentine Bunchgrass Grassland	acres	4,000
Serpentine Rock Outcrop / Barrens	acres	120
Serpentine Seep	acres	10
Rock Outcrop	acres	10
Northern Mixed Chaparral / Chamise Chaparral	acres	400
Mixed Serpentine Chaparral	acres	700
Northern Coastal Scrub / Diablan Sage Scrub	acres	1,400
Valley Oak Woodland	acres	1,700
Mixed Oak Woodland and Forest	acres	7,100
Blue Oak Woodland	acres	1,100
Coast Live Oak Forest and Woodland	acres	2,900
Foothill Pine - Oak Woodland	acres	80
Mixed Evergreen Forest	acres	20
Willow Riparian Forest and Scrub and Mixed Riparian Forest and Woodland	acres	917
Central California Sycamore Alluvial Woodland	acres	54
Redwood Forest	acres	10
Ponderosa Pine Woodland	acres	0
Knobcone Pine Woodland	acres	0
Coastal and Valley Freshwater Marsh	acres	95
Seasonal Wetland	acres	60
Pond	acres	177
<b>Total</b>	<b>acres</b>	<b>34,153</b>
<b>Streams (overlay, included in acres above)</b>	<b>miles</b>	<b>110.4</b>

Note: Actual acquisitions of Reserve System lands are likely to be greater than the minimum necessary to contribute to the recovery of covered species because the Plan also includes requirements (e.g., connectivity, protection of plant occurrences) that will result in additional acquisitions and because parcels purchased to meet a specific requirement will include additional acres of non-target land cover types. The numbers presented in this table represent a hypothetical Reserve System that would meet the requirements of the Plan. Restored /created habitat is counted in the wetland land cover to which is it restored, generally from grassland.

**Table G-0d1: Reserve Area Acquired by Land Cover Type by Time Period**

Land Cover Type	Implementation Period (Years)											Total

**Table G-0e: Habitat Acquired for Reserve System by Species** (Source: Table 5-17 for wildlife and Table 5-16 for covered plants)

**Final Plan**

Species	Unit	Habitat Monitored	
California Red-Legged Frog	acres	1,300	Primary (Breeding)
California Red-Legged Frog (streams)	miles	n/a	Primary (Breeding)
California Tiger Salamander	acres	150	Breeding
California Tiger Salamander (streams)	miles	n/a	Primary (Breeding)
Pond Turtle	acres	7,000	Primary (Breeding)
Pond Turtle (streams)	miles	n/a	Primary (Breeding)
Foothill Yellow-Legged Frog (streams)	miles	30	Primary (Breeding)
San Joaquin Kit Fox	acres	4,000	Secondary habitat (dispersal)
Western Burrowing Owl (overwintering)	acres	-	Overwintering
Western Burrowing Owl (breeding)	acres	-	Breeding
Townsend's Bat	acres	n/a	Roosting
Least Bell's Vireo	acres	600	Primary (Breeding)
Tricolored Blackbird	acres	1,000	Primary (Breeding)
Golden Eagle	acres	n/a	Primary (Breeding)
Bay checkerspot butterfly	acres	3,800	Primary (Breeding)
Covered Plants	occurrence	159	Primary (Breeding)

Assumptions / Notes:

Although the commitment to Least Bell's Vireo (LBV) protection is only 460 acres (per Table 5-17), the monitoring cost estimate is conservatively based on 600 acres of LBV habitat that may be protected

Employee cost per period				\$232,538	\$1,971,203	\$2,040,964	\$2,087,471	\$2,133,979	\$2,133,979	\$2,133,979	\$2,133,979	\$2,133,979	\$2,133,979	\$2,133,979

Assumptions / Notes:

The position of senior scientist is included in shared staff and overhead.

JPA employee costs are not included in the program administration cost category.

Admin - Secretary time is allocated 50% to program administration and 50% to reserve management.

10% Proportion of shared staff, equipment, vehicle, and travel costs allocated to program administration

**Table G-1b: Office Space**

Cost per square foot per month, including utilities	Total space leased per period (square feet)										
	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50
\$2.12	2,000	2,000	2,000	2,000	2,000	2,000	2,000	2,000	2,000	2,000	2,000

Uniform annual cost	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0
Uniform cost per period	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0

Assumptions / Notes:

\$0	Annual cost for t-shirts and polos for all employees
-----	--

**Table G-1m: Legal Assistance**

	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50
Hours per period	-	1,000	1,000	1,000	1,000	1,000	1,000	1,000	1,000	1,000	1,000
Legal assistance cost per period	\$0	\$371,000	\$371,000	\$371,000	\$371,000	\$371,000	\$371,000	\$371,000	\$371,000	\$371,000	\$371,000

Assumptions / Notes:

\$371	Hourly rate for legal assistance
-------	----------------------------------

Assumes outside legal counsel or cost of in-house counsel shared from a partner agency, particularly after start-up period.

The legal assistance category covers legal assistance required under the program administration and land acquisition cost categories.

**Table G-1n: Financial Analysis Assistance**

	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50
Cost per 5-year period	\$0	\$37,100	\$74,200	\$74,200	\$37,100	\$74,200	\$74,200	\$37,100	\$74,200	\$74,200	\$37,100
Financial analysis cost per period	\$0	\$37,100	\$74,200	\$74,200	\$37,100	\$74,200	\$74,200	\$37,100	\$74,200	\$74,200	\$37,100

Assumptions / Notes:

The financial analysis assistance category covers the periodic assistance of a financial analyst to review the program's cost/revenue balance and ensure that charges are adjusted in line with changing land costs.

After start-up, financial analyst review will occur once every 3 years (years 3,6,9,12,15,18,21,24,27,30,33,36,39,42,45, and 48).

Total before contingency	\$3,600,000	\$25,050,333	\$28,650,333	\$28,650,333	\$28,650,333	\$28,650,333	\$28,650,333	\$28,650,333	\$28,650,333	\$28,650,333	\$0	
Total with contingency	\$3,708,000	\$25,801,843	\$29,509,843	\$29,509,843	\$29,509,843	\$29,509,843	\$29,509,843	\$29,509,843	\$29,509,843	\$29,509,843	\$0	

Assumptions / Notes:

Easements assumed for agricultural land and ranchland per the assumptions below.

300	Number of acres acquired in Remote West Hills during plan development (one transaction, fee title).
200	Number of acres acquired in Near East Hills during plan development (one transaction).
11.1%	Percent of each land cover type acquired in each 5-year period beginning in year 1, assuming acquisition complete by year 45, and acres acquired during plan development deducted from first period.
0%	Percent of Valley Floor that is agricultural land in the Pajaro River Valley that will be acquired using conservation easements
50%	Percent of Remote and Near Hills that is ranchland that will be acquired using conservation easements.
80%	Percent of fee title cost required for easement acquisition
3%	Contingency factor for land acquisition and site improvements

**Table G-3b: Proposed Land Acquisition Cost Assumptions, by location and parcel size (fee title purchase price per acre in 2007 dollars)**

Location	Less than 50 acres		
	50 - 250 acres	Over 250 acres	
Near East Hills	\$28,000	\$9,000	\$8,000
Near West Hills	\$28,000	\$9,000	\$8,000
Remote East Hills	\$10,000	\$9,000	\$6,000
Remote West Hills	\$10,000	\$9,000	\$6,000
Almaden Valley / Valley Floor	\$34,000	\$17,000	\$16,000

For cost estimating purposes, land costs assumed to remain constant (in real terms) over time. See Chapter 9 for automatic and periodic inflation factors that are built into the fees to account for expected increases in land cost over time.

**Assumptions / Notes:**

Site improvements for land acquired during plan development assumed to occur during years 1 -5 of plan implementation.

Road and fencing improvements will facilitate grazing operations for ongoing landscape management.

\$11.66	Average cost of new fence installation by linear foot, once land is acquired
\$4.24	Average cost per linear foot for boundary fence repair or removal upon acquisition
27,800	Average linear feet of new fencing installed upon acquisition per 5-year time period; function of acquisitions over time
12,500	Average linear feet of existing fencing per acquisition
35%	Proportion of existing boundary fence that needs repair or removal at acquisition
\$106,000	Average cost per mile for road obliteration upon acquisition (re-contouring to natural contours, compaction, erosion control, seeding with natives and weed control)
0.3	Average miles of road obliterated upon acquisition per 1,000 acres acquired
\$21,200	Average cost per mile for road stabilization and abandonment upon acquisition (erosion control measures, removal of stream crossing reastures, ripping roadbed, etc.)
0.5	Average miles of road stabilization and abandonment upon acquisition per 1,000 acres acquired
3%	Contingency factor for land acquisition and site improvements

Ogier Ponds project	dollars	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0
Total before contingency			\$0	\$8,160,593	\$8,160,593	\$8,160,593	\$8,160,593	\$8,160,593	\$8,160,593	\$8,160,593	\$8,160,593	\$0	\$0
Restoration contingency			\$0	\$1,224,089	\$1,224,089	\$1,224,089	\$1,224,089	\$1,224,089	\$1,224,089	\$1,224,089	\$1,224,089	\$0	\$0

Assumptions / Notes:

All restoration projects implemented by year 40.

Reserve staff would prepare restoration management plans.

Restoration planning, design, and implementation will be accomplished through a combination of contractors with staff oversight and management.

The estimate of construction costs is a planning tool to assess the level of effort required to perform the work. Actual construction costs may vary from the above estimates because of competitive bidding, negotiations with the client, or fluctuations in market prices. This is not a bid.

Plan, specification, and engineering work, bid assistance, and construction oversight are accounted for in the 5-year period in which construction takes place.

Five years of post-construction maintenance will be conducted in the 5-year period after construction takes place.

Post-construction restoration monitoring and maintenance is a 5-year period of staff monitoring and contractor remediation to ensure successful implementation of plan drawings,

15% Contingency factor for restoration/creation; assumed to be higher than standard contingency

0.0 Miles of stream restored in Ogier Ponds project, expected in years 6-10

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-4: Habitat Restoration/Creation  
Final Plan**

**2010 dollars**

Detail may not add to total due to rounding at various stages of the calculations.

**G-4c Environmental Compliance for Restoration Projects**

Number Projects Requiring Environmental Compliance

Project size	Size Range	Number of projects per period										Total	
		0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45		46-50
Small/simple	up to 10 acres or up to 0.1 stream miles	-	9	9	9	9	9	9	9	7	-	-	70
Medium/more complex	10.1-50 acres or 0.1-0.5 stream miles	-	5	5	5	5	5	5	5	-	-	-	35
Large/most complex	over 50 acres or 0.5 stream miles	-	1	1	1	1	1	1	1	-	-	-	7
Total projects		-	15	15	15	15	15	15	15	7	-	-	112

Assumptions / Notes:

**12.50%** Percentage of projects requiring compliance in each 5-year period between years 1 and 40; linked to restoration over time

Cost per Project Size and Compliance Category

Project size	Compliance Category			Total
	CWA 404/401	CDFG 1602	Other	
Small/simple	\$5,300	\$2,650	\$10,600	\$18,550
Medium/more complex	\$10,600	\$4,240	\$10,600	\$25,440
Large/most complex	\$26,500	\$8,480	\$10,600	\$45,580

For 401/404 and 1602 compliance, varying costs have more to do with project complexity than with project size.

Clean Water Act and 1602 permits will be done on a per-project basis; a Regional General Permit and Master 1602 Agreement will be available for small to medium projects.

All compliance costs include application or other fees

**401/404**

The cost of conducting wetland delineations is not included under CWA 404/401 compliance; it is expected that delineation would be covered under land acquisition costs.

Each project implemented under the HCP will qualify for compliance under the regional permit program for the inventory area

Tasks associated with Section 402 compliance are not included in this cost estimate.

**1602**

All projects except large ones would qualify for the Master 1602 for the inventory area

**Other**

The "other" compliance category could include county grading permits, road encroachment permits, or other local approvals.

Includes preparation of a Storm Water Pollution Prevention Plan (SWPPP) in compliance with Regional Water Quality Control Board General Construction Permit.

Applicable to any project resulting in more than one acre of ground disturbance, assumed to be most restoration projects.

**Table G-4d: Staff (shared with administration, reserve management, and monitoring)**

	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50

**Table G-4: Habitat Restoration/Creation  
Final Plan**

**2010 dollars**

Detail may not add to total due to rounding at various stages of the calculations.

**Table G-4i: Long-term management**

	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50
Restored pond acres managed (cumulative total)	0.0	9.0	18.0	27.0	36.0	45.0	54.0	63.0	72.0	72.0	72.0
Restored acres managed for feral pigs (cumulative)	0.0	47.9	95.8	143.6	191.5	239.4	287.3	335.1	383.0	383.0	383.0
Restored acres managed for cowbird (cumulative)	0.0	42.4	84.8	127.1	169.5	211.9	254.3	296.6	339.0	339.0	339.0
Cost of feral pig management per period	\$0	\$317	\$634	\$952	\$1,269	\$1,586	\$1,903	\$2,220	\$2,537	\$2,537	\$2,537
Cost to control brown headed cowbird, per period	\$0	\$6,738	\$13,475	\$20,213	\$26,951	\$33,688	\$40,426	\$47,163	\$53,901	\$53,901	\$53,901
Cost to control non-native fish in ponds, per period	\$0	\$1,431	\$2,862	\$4,293	\$5,724	\$7,155	\$8,586	\$10,017	\$11,448	\$11,448	\$11,448
Pond maintenance	\$0	\$14,310	\$28,620	\$42,930	\$57,240	\$71,550	\$85,860	\$100,170	\$114,480	\$114,480	\$114,480
Operational cost per period	\$0	\$22,796	\$45,592	\$68,387	\$91,183	\$113,979	\$136,775	\$159,571	\$182,366	\$182,366	\$182,366
Remedial measures for long-term mngmt.	\$0	\$2,280	\$4,559	\$6,839	\$9,118	\$11,398	\$13,677	\$15,957	\$18,237	\$18,237	\$18,237

Assumptions / Notes:

Invasive species management on restored lands assumes grassland is restored to wetlands. While some other land covers may also be restored to wetlands, the majority will be grasslands.

\$32 Cost to control brown-headed cowbird per year per acre managed. Would occur periodically in strategic locations throughout the reserve system.

0.50 Acres per pond (Table 5-12)

30% Percent of ponds managed for control of non-native fish

0.5 Number of management activities (applications) per pond per year to control non-native fish assuming management occurs every other year.

\$106 Cost to control non-native fish per pond per application (supplies only, not labor).

Note: Management activities for non-native fish will be done by reserve staff. Costs for management for non-native fish in ponds in existing open space covered in Table G-5m.

**Table G-4j: Long-term biological monitoring**

	Biological Monitoring Cost Per Period by Species

Capital cost of equipment and materials per year	\$0	\$12,067	\$24,135	\$36,202	\$48,270	\$60,337	\$72,404	\$84,472	\$96,539	\$108,607	\$108,607
Operational cost of equipment, materials, and data per year	\$0	\$2,011	\$13,533	\$19,929	\$26,325	\$32,721	\$39,116	\$45,512	\$51,908	\$58,303	\$58,303
Capital cost per period	\$0	\$60,337	\$120,674	\$181,011	\$241,348	\$301,685	\$362,022	\$422,359	\$482,696	\$543,033	\$543,033
Operational cost per period	\$0	\$10,056	\$67,667	\$99,646	\$131,624	\$163,603	\$195,582	\$227,560	\$259,539	\$291,517	\$291,517

Assumptions / Notes:

**\$3,180** Capital cost of other equipment (e.g., hand-held tools and machines) and non-liquid materials (e.g., road gravel) per 1,000 reserve acres per year  
**\$530** Operational cost of equipment per 1,000 reserve acres per year  
**\$3,710** Cost per period to acquire aerial photos every 5 years to re-map land cover. Labor provided by Implementing Entity staff.

Capital costs include the capital component of fire fighting equipment/gear, small tools (pliers, wrenches, screwdrivers, etc.), glasses, gloves, hard hats, rain gear, irrigation supplies, cargo container, landscape plants and grass, oak trees, lumber, and truck hauling services.  
Operational costs include the operational component of fire fighting equipment/gear, small tools (pliers, wrenches, screwdrivers, etc.), glasses, gloves, hard hats, rain gear, irrigation supplies, cargo container, landscape plants and grass, oak trees, lumber, and truck hauling services.  
Operational costs also include portable radios, small pumps, piping, generator, saw, and demolition hammers.  
Grazing is assumed to be an important tool in landscape management on ranchland under conservation easements or grazing leases.

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-5: Reserve Management and Maintenance  
Final Plan**

**2010 dollars**

Detail may not add to total due to rounding at various stages of the calculations.

**Table G-5i: Field Facilities**

	Number of facilities and facility construction costs per period										
	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50
Reserve acres managed (cumulative total)	-	3,795	7,590	11,384	15,179	18,974	22,769	26,563	30,358	34,153	34,153
Number of field facilities	-	1	1	1	2	2	3	3	3	3	3
New field facilities	-	1	-	-	1	-	1	-	-	-	-
Field facility construction cost per period	\$0	\$557,295	\$0	\$0	\$557,295	\$0	\$557,295	\$0	\$0	\$0	\$0
New native plant nurseries constructed	-	-	-	-	-	-	-	-	-	-	-
Native plant nursery construction cost per period	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0
Total facility construction cost per period	\$0	\$557,295	\$0	\$0	\$557,295	\$0	\$557,295	\$0	\$0	\$0	\$0
Establish permanent seed bank for 6 species	\$0	\$63,600	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0

Assumptions / Notes:

10,000	Threshold for acres of reserve served by each workshop/parking area
\$530,000	Cost to build a workshop/parking area
\$0	Cost to build native plant nursery (\$75,000)
\$795	Cost of pre-construction surveys per project
5%	Construction oversight and monitoring as percent of construction cost
\$63,600	One-time cost to establish permanent seed bank collection

Field facilities contain an area for equipment storage, a manager's office, a shared office, a locker room, restrooms, and a parking area.

Native plant nursery facilities assumed shared with other land management entities.

The seed bank collection will be established at the Rancho Santa Ana Botanic Gardens (or similar institution). Costs account for seed bank collection design, collection time by consultants or implementing Entity staff,

seed banking fees at the storage institution, and miscellaneous expenses.

Six covered plant species would be established at the permanent seed bank: Santa Clara Valley dudleya, coyote ceanothus, most beautiful jewel-flower, Metcalf Canyon jewel-flower, smooth lessingia, and Mt. Hamilton thistle.

Seed bank established during years 1 - 5.

**Table G-5j: Facilities Maintenance and Utilities**

	Cost per facility per year	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50
Total field facilities per period	-	-	1	1	1	2	2	3	3	3	3	3

Cost to control non-native fish in ponds, per year	\$0	\$625	\$1,251	\$1,876	\$2,502	\$3,127	\$3,752	\$4,378	\$5,003	\$5,629	\$5,629
Cost per year	\$0	\$26,745	\$53,490	\$80,236	\$106,981	\$133,726	\$160,471	\$187,217	\$213,962	\$240,707	\$240,707
Cost per period	\$0	\$133,726	\$267,452	\$401,179	\$534,905	\$668,631	\$802,357	\$936,084	\$1,069,810	\$1,203,536	\$1,203,536

Assumptions / Notes:

\$530	Cost of weed management supplies (not labor) per 1,000 acres of reserve per year, for hand spraying. Applies to all reserve acres
\$27	Cost of applications of herbicides per period per acre managed
\$48	Cost of prescribed burns per acre burned
\$1,325	Cost of feral pig management per year per 1,000 acres managed
\$32	Cost to control brown-headed cowbird per year per acre managed. Would occur periodically in strategic locations throughout the reserve system.
1,242	Acres managed with prescribed burns (total in year 50)
177	Acres of ponds acquired and restored in lieu of herbicides and prescribed burns. Some rangeland may be leased for grazing and some ranchland acquired with conservation easements will be grazed.
0.5	Acres per pond (Table 5-12)
30%	Percent of ponds managed for control of non-native fish
0.5	Number of management activities (applications) per pond per year to control non-native fish assuming management occurs every other year.
\$106	Cost to control non-native fish per pond per application (supplies only, not labor).

Note: Bullfrog management activities will be conducted by reserve staff. All herbicides applied according to label instructions. Pesticides may be applied using aerial, truck, or hand application.

Grazing will be used as applicable for weed management in lieu of herbicides and prescribed burns. Some rangeland may be leased for grazing and some ranchland acquired with conservation easements will be grazed.

Note: Management activities for non-native fish will be done by reserve staff. Costs for management for non-native fish in ponds in existing open space covered in Table G-5m.

Invasive species control on restored wetlands covered as a restoration cost.

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-5: Reserve Management and Maintenance  
Final Plan**

**2010 dollars**

Detail may not add to total due to rounding at various stages of the calculations.

**Table G-5m: Management of existing open space**

	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50
Cost per period for County Parks	\$0	\$0	\$3,910,340	\$3,910,340	\$3,910,340	\$3,910,340	\$3,910,340	\$3,910,340	\$3,910,340	\$3,910,340	\$3,910,340
Cost per period for Open Space Authority lands	\$0	\$0	\$477,000	\$477,000	\$477,000	\$477,000	\$477,000	\$477,000	\$477,000	\$477,000	\$477,000

Assumptions / Notes:

\$782,068	Annual cost to manage existing open space (County parks managed for the Habitat Plan)
\$95,400	Annual cost to manage existing open space (Open Space Authority lands managed for the Habitat Plan)

Management activities begin in year 6.

Does not include other costs such as recreation and law enforcement / public safety because those services are already provided by County Parks and the County Sheriff.

**Table G-5n: Contractors - for on-going management and maintenance** (For all acres acquired, including restored acres. Restoration share calculated in G-4i. Reserve management total above deducts cost allocated to restored lands.)

Contractor category	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50

Assumptions / Notes:

\$106,000	Reserve unit management plans: One for each of five reserve units. Cost per initial plan. First 3 written in first five years and another 2 written in second five years.
\$21,200	Cost to update reserve unit management plan once every 5 years.
\$1,590	Cost for pond maintenance (dredging) per acre of pond every 5 years
\$1,060	Cost of dirt (ranch) road maintenance per mile of road per year
0.75	Miles of dirt (ranch) road constructed, per 1,000 acres acquired
\$2,650	Cost for other maintenance services per 1,000 acres of reserve per year

Costs for Neighboring Landowner Agreement baseline and land cover surveys would be incurred by the landowner.

Other maintenance services include mowing, grading, pest control, diskling for fire breaks, fencing, alarms, janitorial services, removing debris associated with illegal marijuana cultivation.

Pond maintenance services on restored ponds covered as a restoration cost.

**Table G-5n: Contractors - capital costs for construction services including roadway design, paving, fencing, grading, and surveying services**

Contractor category	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50
Total miles of paved roads (cumulative)	-	-	-	-	-	-	-	-	-	-	-
Paved road construction	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0
Dirt (ranch) road construction	\$0	\$130,683	\$130,683	\$130,683	\$130,683	\$130,683	\$130,683	\$130,683	\$130,683	\$130,683	\$0
Bridge installation	\$0	\$334,298	\$334,298	\$334,298	\$334,298	\$334,298	\$334,298	\$334,298	\$334,298	\$334,298	\$334,298
Wildlife linkages implementation	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0	\$0
Cost per period	\$0	\$464,980	\$464,980	\$464,980	\$464,980	\$464,980	\$464,980	\$464,980	\$464,980	\$464,980	\$334,298

Assumptions / Notes:

\$84,800	Cost for paved road construction per mile
\$42,400	Cost for dirt (ranch) road construction per mile
-	Miles of paved road constructed, per 1,000 acres acquired
0.75	Miles of dirt (ranch) road constructed, per 1,000 acres acquired
1	Number of vehicle bridges installed per period
\$636,000	Cost per vehicle bridge to install
-	Number of trail bridges installed per period
\$22,260	Cost per trail bridge to install
\$795	Cost of pre-construction surveys (per year for road construction and per project for bridge installation)
5%	Construction oversight and monitoring as percent of construction cost
\$0	Seed money to implement recommendations of feasibility study regarding wildlife linkages (originally \$1,500,000)

\$814,549  
\$2,715,164

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-5: Reserve Management and Maintenance  
Final Plan**

**2010 dollars**

Detail may not add to total due to rounding at various stages of the calculations.

**G-5o Environmental Compliance for Reserve Management Projects**

Number Projects Requiring Environmental Compliance

Project size	Size Range	Number of projects per period										Total	
		0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45		46-50
Small/simple	up to 10 acres or up to 0.1 stream miles	-	9	9	9	9	9	9	9	7	-	-	70
Medium/more complex	10.1-50 acres or 0.1-0.5 stream miles	-	5	5	5	5	5	5	5	-	-	-	35
Large/most complex	over 50 acres or 0.5 stream miles	-	1	1	1	1	1	1	1	-	-	-	7
Total projects		-	15	15	15	15	15	15	15	7	-	-	112

Assumptions / Notes:

**12.50%** Percentage of projects requiring compliance in each 5-year period between years 1 and 40; linked to restoration over time

Cost per Project Size and Compliance Category

Project size	Compliance Category		
	NEPA/CEQA	NHPA	Total
Small/simple	\$5,300	\$2,650	\$7,950
Medium/more complex	\$42,400	\$3,710	\$46,110
Large/most complex	\$106,000	\$9,010	\$115,010

For NEPA/CEQA compliance, varying costs have more to do with project complexity than with project size.

Cultural compliance permits will be done on a per-project basis.

All compliance costs include application or other fees

All land acquisitions would be a categorical exemption under CEQA as well as under NEPA, when NEPA applies.

**NEPA/CEQA**

Depending on the level of detail that is provided for specific projects, they may or may not be able to be covered under the HCP EIR/EIS.

For those without sufficient detail, additional environmental documentation may need to be prepared.

It is likely that the majority of those would be in the form of mitigated negative declarations.

Because it is difficult to provide a cost estimate for a project without knowing details such as location, size, etc.,

the following are some rough numbers based on level of controversy:

Small scale non-controversial projects = Cat Excl/Cat Exemp

Medium scale more controversial projects = IS MND/EA FONSI

Larger scale more controversial projects = EIR/EIS

**NHPA**

Archaeological surveys can be conducted at an intensive level at a rate of 40 acres per person per day.

No more than one cultural resource will be identified per 40 acres or part thereof.

This scope of work and cost estimate does not include tasks necessary for significance evaluations and resolution of adverse effects.

**G-5p: Remedial Measures**

Capital Budget	Implementation Period (Years)											Total
	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50	
Remedial measures	\$0	\$228,556	\$745,968	\$739,066	\$818,280	\$820,126	\$878,598	\$880,444	\$895,619	\$894,179	\$894,179	\$7,795,016
<b>Total</b>	<b>\$0</b>	<b>\$228,556</b>	<b>\$745,968</b>	<b>\$739,066</b>	<b>\$818,280</b>	<b>\$820,126</b>	<b>\$878,598</b>	<b>\$880,444</b>	<b>\$895,619</b>	<b>\$894,179</b>	<b>\$894,179</b>	<b>\$7,795,016</b>

Assumptions / Notes:

**10%** Percent of reserve management and maintenance operational cost assumed to be needed for remedial actions on reserve lands.

Applies to operational budget for management activities on reserve lands.

Applies to western burrowing owl conservation strategy management costs from Table G-7.

Management costs include overall reserve management.

Covers costs associated with responses to adaptive management findings as well as costs for restoration or maintenance of reserve areas in response to other changed circumstances such as wildfire or drought.

Remedial measures for restoration activities are included as a restoration cost.

Compliance monitoring for implementation will be conducted by program administration staff and is addressed under the program administration cost category.

General landscape level surveying and monitoring will be done by staff, once every 5 years.

Pre-acquisition survey costs are covered under the land acquisition cost category.

Monitoring on lands restored/created is addressed under the restoration cost category.

Pre-construction surveys are assumed to occur prior to construction of covered activities on the reserve system, and costs are estimated as a component of those restoration and management costs.

Construction monitoring is assumed to occur periodically during construction of covered activities and conservation measures, and costs are estimated as a component of those restoration and management costs.

Implementing entity monitoring staff will plan, coordinate, and report on the monitoring categories described below.

Contractors will conduct the field monitoring and data analysis.

Annual monitoring costs assumed roughly constant over the implementation period. More intensive monitoring in early years; monitoring becomes more efficient over time.

Pre-acquisition, pre-construction surveys, and construction monitoring for covered activities outside of the reserve system will be paid for by developers.

159	Total covered plant occurrences protected, including the occurrences on existing open space, number protected by the Plan and the number created
5	Hours of covered plant surveying per occurrence per year
\$0	Annual cost to monitor Townsend's bat maternity colonies
2.2%	Percent of each species and/or land cover added each year beginning in year 1, assuming 45-year acquisition period.
15%	Percent premium on costs in years 1 - 10 to reflect more intensive early efforts and the fact that monitoring would become more efficient over time.
\$127	Contractor cost per hour including amortized per diem and travel
5	years per period

# Santa Clara Valley Habitat Plan Implementation Budget

**Table G-6: Monitoring, Research, and Scientific Review  
Final Plan**

**2010 dollars**

Detail may not add to total due to rounding at various stages of the calculations.

**Table G-6h: California Tiger Salamander: Management plan, baseline genetic study, and on-going genetic monitoring for hybridization**

The objective of the management plan and baseline genetic study is to determine the percent of non-native genes in occupied sites (ponds/wetlands) and develop a management plan based on the data.

The objectives of the on-going monitoring are to inform the adaptive management process associated with the Management Plan, evaluate effectiveness of management/restoration,

and inform decision-making regarding CTS habitat restoration/acquisition.

	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50

Assumptions / Notes: **215** total acres of CTS breeding habitat monitored by year 45, includes acquired reserve land and existing open space (Table 5-17)

Reserve system commitment by time period (Table 5-14)	Year 15	Year 30	Year 45
	30%	70%	100%
CTS potential breeding habitat (acres) by time period, cumulative	65	151	215

Baseline study data collection will occur during the first 15 years of plan implementation due to the relatively low number of ponds/wetlands within the Reserve System at the onset of the permit.

Breeding habitat is added relatively evenly over time, and hybridization is only monitored within Reserve System lands.

If a habitat is occupied, genetic samples will be collected and that habitat will be sampled again every three years.

Three years of sampling are required to determine habitat as unoccupied.

Two people (Project Leader/Permitted Specialist and Senior Field Crew) are required for each potential breeding habitat site visit.

A field season includes time for the following activities: personnel management, project planning, data collection, data entry and management, and report writing.

5	Average annual acres of potential breeding habitat added for the first 15 years of the permit term
6	Average annual acres of potential breeding habitat added years 16 - 30 of the permit term
4	Average annual acres of potential breeding habitat added years 30 - 45 of the permit term
30%	Percent of potential breeding habitat that is occupied habitat and therefore re-visited every three years for tissue collection purposes
20	Number of samples collected per occupied site
2	Number of pond/wetland sites visited per day, first 5 years
2.5	Number of sites visited per day, beginning in year 6
5	Days per year for project-related duties for Project Leader and for Senior Field Crew
\$140	Project Leader / Permitted Specialist, hourly rate
\$100	Senior Field Crew, hourly rate
\$150	Cost per sample for genetic testing, lab component
\$3,500	Annual cost for genetic testing: analysis and method design

	16-20	21-25	26-30	31-35	36-40	41-45	46-50
Collection equipment	\$1,500	\$1,500	\$1,500	\$1,500	\$1,500	\$1,500	\$1,500
Tissue sampling equipment	\$1,500	\$1,500	\$1,500	\$1,500	\$1,500	\$1,500	\$1,500
Project Leader/Permitted Specialist (8 hours per day)	\$37,240	\$40,264	\$43,288	\$45,808	\$47,824	\$49,840	\$50,848
Senior Field Crew (8 hours per day)	\$26,600	\$28,760	\$30,920	\$32,720	\$34,160	\$35,600	\$36,320
Genetic testing: lab component	\$61,875	\$82,125	\$102,375	\$119,250	\$132,750	\$146,250	\$153,000
Genetic testing: analysis and method design	\$17,500	\$17,500	\$17,500	\$17,500	\$17,500	\$17,500	\$17,500
Cost per period	\$146,215	\$171,649	\$197,083	\$218,278	\$235,234	\$252,190	\$260,668

15%	Percent of all occupied sites visited annually.
\$300	Annual cost for collection equipment (waders, nets, dip nets, buckets, etc.)
\$300	Annual cost for tissue sampling equipment (collection jars, clippers, labels, notebooks, etc.)

Assumptions:  
New potential breeding habitat acreage will continue to be added to the Reserve, so baseline monitoring will continue to determine occupancy and percent non-native gene frequencies.  
Ponds/wetlands will be acquired/restored as part of the Conservation Plan, adding additional monitoring needs.  
Representative ponds/wetlands will continue to be monitored at about the same frequency as with the hybridization/population monitoring.  
All occupied sites will be visited and sampled on a regular basis, as stipulated by the Management Plan. For the purpose of this model, it is assumed occupied sites will be revisited every 5 years.

**Table G-7a: Grazing on managed land**

Cost to allow grazing to manage potential burrowing owl habitat.

Acres managed by grazing	0	1-5	6-10	11-15	16-20	21-25	26-30	31-35	36-40	41-45	46-50
Baylands Region	-	222	222	444	444	666	666	888	888	1,110	1,110
Gilroy Region	-	48	48	96	96	144	144	192	192	240	240
Morgan Hill Region	-	32	32	64	64	95	95	127	127	159	159
South San José Region	-	16	16	32	32	49	49	65	65	81	81
Cost per year	\$0	\$31,800	\$31,800	\$63,600	\$63,600	\$95,400	\$95,400	\$127,200	\$127,200	\$159,000	\$159,000
Cost per period	\$0	\$159,000	\$159,000	\$318,000	\$318,000	\$477,000	\$477,000	\$636,000	\$636,000	\$795,000	\$795,000

Assumptions/Notes:

Only 600 acres of occupied burrowing owl habitat will be acquired in fee title or conservation easement; these 600 acres are consistent with the reserve system and will be acquired consistent with impacts.

Due to the cost of acquisition and because owl nesting habitat does not overlap with many other covered species, 4,700 acres of managed lands are not expected to be the same as lands acquired for the Plan,

The Implementing Entity will partner with County Parks, OSA, TNC, or other organization protecting lands on the Valley floor.

The management agreements would be at least 10 years long and as such, managed lands would increase incrementally every 10 years.

That costs would be consistent for 10 year periods, and they should be accounted for at the beginning of the 10-year period.

The acreage of managed lands will never drop, and the acreage of managed lands will increase incrementally over time.

\$100	Dollars per acre annual cost for grazing, including fencing and access control	
30%	Percent of lands managed by grazing	
	Total acres managed (grazed) at end of permit term	Total land management commitment
Location		
Baylands Region	3,700	70%
Gilroy Region	800	15%
Morgan Hill Region	530	10%
South San José Region	270	5%
<b>Total acres</b>	<b>5,300</b>	<b>100%</b>

\$53,000	35%	Administrative Assistant	-	250	0.5	1.0
\$100,700	35%	Senior Scientist	3	-	0.5	0.5
\$90,100	35%	Project Manager/Conservation Planner	1	-	0.0	1.0
\$90,100	35%	Reserve Manager	-	-	0.5	0.5
\$68,900	35%	Field Staff	-	-	2.0	5.0
\$53,000	35%	Laborer	-	-	0.0	0.0
Total					4.50	10.50
Annual Average turnover staff beyond permit term: assumes full turnover every 2.5 years					1.80	
Old Staff Remaining					2.70	

50%	Admin-Secretary time allocated to program administration
50%	Admin-Secretary time allocated to reserve management
\$186	Travel allowance per diem
3.00	Per diem multiplier for executive director to cover additional travel expenses such as airfare
\$0.514	Cost per mile for travel allowance
50%	Post-permit adjustment for overnight travel and mileage allowance (percent of annual amount during permit term)
<b>Overhead cost allocation</b>	
10%	Proportion of shared staff, equipment, vehicle, and travel costs allocated to program administration
35%	Proportion of shared staff, equipment, vehicle, and travel costs allocated to management
35%	Proportion of shared staff, equipment, vehicle, and travel costs allocated to restoration
20%	Proportion of shared staff, equipment, vehicle, and travel costs allocated to monitoring and research

#### Equipment and Vehicles

##### Office Equipment per employee

Annualized Cost per FTE per replacement period	Cost of service contract per year	Equipment type	Adjusted Replacement Period (years)
\$53		Common office furniture	40
\$53		Cubicle furniture	40
\$265		Office supplies (annual)	2
\$442	\$44	Computers	6
\$159	\$32	Cell phones	4
\$159	\$106	Mobile radios	6
2		unit of common office furniture purchased each replacement period	
1		Mobile radio per vehicle	
2		Post-permit adjustment for replacement period (multiple for replacement period)	

##### General Office Equipment

Cost per year (leased items) / Annualized cost per item per replacement period (purchased items)	Cost of service contract per item per year	Type of Equipment
\$1,144	\$0	Color printer/copy machine/scanner (lease)
\$6,240	\$0	Office telephone systems (lease)
\$1,560		Books and journals (purchase)
\$26		New fax machines purchased
		Old fax machines retired
	\$0	Total fax machines
\$146		New printers purchased
		Old printers retired
	\$0	Total printers
\$84		New digital cameras purchased
		Old digital cameras retired
	\$0	Total digital cameras
\$130		Radio base station purchased
		Radio base station retired
	\$104	Total radio base stations
\$6,230		Trunked radio system (shared tower and repeaters)
Assumes printer and phone maintenance/service contracts provided at no cost by Permittees.		
10		year replacement period for fax machine and printer.
6		year replacement period for digital cameras.
20		year replacement period for radio base station.
2		Post-permit adjustment for replacement period (multiple for replacement period)

# Santa Clara Valley Habitat Plan Implementation Budget

## Assumptions for costs in perpetuity

**Table G-9: Master list of assumptions used to develop Habitat Plan budget**  
**Assumptions for annual budget beyond permit term**

### Technology Equipment and Services

Annualized Cost per item per replacement period	Cost of software update or service contract per year	Type of Equipment
\$0		New GIS/database servers purchased
		Old GIS/database servers retired
	\$0	Total GIS/database servers
\$520		New tablet PC purchased
		Old tablet PCs retired
	\$52	Total tablet PCs
\$1,092		New plotters purchased
		Old plotters retired
	\$83	Total plotters
\$416		New GPS units purchased
		Old GPS units retired
	\$146	Total GPS units
\$0		New GIS software purchased
		Old GIS software retired
	\$0	Total GIS software
\$520		New computer software purchased
		Old computer software retired
	\$121	Total computer software
\$21,200	annual cost of contract GIS services, years 26 - 50	
10	year replacement period for GIS and database equipment purchased.	
6	year software upgrade cycle	
2	Post-permit adjustment for replacement period (multiple for replacement period)	

### Vehicles and Fuel

Annualized purchase price per vehicle per replacement period	Fuel cost per vehicle per year		Maintenance cost per vehicle per year	Annual Average Vehicles Post Permit	Number of Vehicles Years 46-50
\$1,061	\$1,560	Passenger cars	\$1,248	1	1
\$3,120	\$2,080	4WD trucks	\$2,080	2	2
\$832	\$416	ATVs and trailers	\$520	1	1
		Total vehicles		4	
20	year replacement period for passenger vehicle				
10	year replacement period for 4WD truck				
10	year replacement period for ATV				
2	Post-permit adjustment for replacement period (multiple for replacement period)				

### Leased Vehicle/Equipment

\$47,280	Annual average lease cost in year 50
100%	Post-permit adjustment: percentage of annual costs in year 50 that continue in perpetuity

### Other Program Administration

#### Office Space

Assumes Implementing Entity will share office space with existing agencies.

2,000	Total space leased per period (square feet)
\$2.12	Cost per square foot per month
100%	Post-permit adjustment: percentage of annual costs in year 50 that continue in perpetuity

#### Utility Costs

Utility costs included in office lease costs, above.

\$0.00	Annual cost per sq. ft. of office space
--------	---

#### Insurance

\$1,855	Automobile insurance cost per year per vehicle
\$5,830	Directors' and officers' insurance cost per year
\$5,830	General liability insurance cost per year
\$5,745	Professional liability insurance cost per year
100%	Post-permit adjustment for auto, general liability, and professional liability insurance: percentage of annual costs in year 50 that continue in perpetuity
0%	Post-permit adjustment for directors' and officers' insurance: percentage of annual costs in year 50 that continue in perpetuity

#### Staff Training

\$318	Annual cost of training per staff member (excluding travel)
100%	Post-permit adjustment: percentage of annual costs in year 50 that continue in perpetuity

#### Uniforms

\$0	Annual cost for t-shirts and polos for all employees
100%	Post-permit adjustment: percentage of annual costs in year 50 that continue in perpetuity

#### Law Enforcement /Public Safety Costs

Law enforcement costs on existing open space will be covered by County Parks through County Parks Rangers and the County Sheriff.

\$8.48	Law enforcement /public safety cost per reserve acre per year
100%	Post-permit adjustment: percentage of annual costs in year 50 that continue in perpetuity

#### Public Education/Outreach

\$53,000	Annual cost after start-up
50%	Post-permit adjustment: percentage of annual costs in year 50 that continue in perpetuity

## MEMORANDUM

**Date:** April 6, 2012

**From:** Sally Nielsen

**Subject:** **Assessment of Open Space Land Sales Used in the Santa Clara Valley Habitat Plan Economic Analysis**

---

Land acquisition cost factors used in the Santa Clara Valley Habitat Plan budget estimates are based on analysis of land transactions involving open space lands in Santa Clara County. Staff of Smith & Associates compiled the transactions data, and Hausrath Economics Group (HEG) developed the cost factors in consultation with other members of the consultant team and with input from staff of the Santa Clara County Open Space Authority, Santa Clara County Parks and Recreation Department, and The Nature Conservancy. This memorandum presents the detailed transactions and some analyses of the transactions used to identify patterns and trends.

It is important to remember that the average cost factors developed for the purpose of producing planning-level estimates of a permit-term budget for the HCP /NCCP represent a best estimate of an expected cumulative pattern over many transactions. As illustrated in the data that follow, the individual transactions range substantially around the average. Any one transaction will be influenced by a number of property characteristics, including the circumstances and inclinations of the seller.

The original transactions list compiled by Smith & Associates in 2007 consisted of 34 sales. Two of the transactions were easement acquisitions; the rest were fee title transactions. The sources for the list included County Assessor's records and maps, CoStar Comps, a digital mapping system, and information provided by the Management Team including information on transactions completed by the Santa Clara County Open Space Authority, The Nature Conservancy, and the Silicon Valley Land Conservancy. To update estimated costs in 2011, we added information about more recent transactions completed by Santa Clara County Parks and the Santa Clara County Open Space Authority in 2009 and 2010. **Figure 1** at the end of this memorandum lists all of the transactions and shows the type of information gathered about each.

The transactions list used to develop the land cost factors covers transactions dating back to October 1999. The most recent transactions included in the analysis are three Open Space Authority acquisitions concluded in 2010. There are transactions recorded for each of the years in the 1999 – 2010 period.

From the universe of all land sales transactions in Santa Clara County over this time period, the list represents a limited set of sales primarily for open space use. Sales determined to be speculative, i.e., large parcels with agricultural zoning but that could have longer-term subdivision potential, were specifically excluded. Some of the sales do reflect values associated with large home sites on “ranchland” tracts. Almost all of the transactions involve parcels outside urban limit lines and the “Planning Limit of Urban Growth”.

To derive representative average cost factors for use in the Santa Clara Valley Habitat Plan implementation cost and budget analysis, we considered a number of parcel characteristics: parcel size, topography, location, and land cover. Location captured the variations in topography and many of the variations in land cover, so we focused the analysis on location and parcel size.

**Figure 2** defines the locations used in the land cost analysis. We used the same zones defined for the impact assessment of rural development, combining Almaden Valley and Valley Floor because of the small number of sales observations in these areas and the similarity in parcel characteristics. Because of the small number of transactions identified in the Remote Hills, we used the full range of Hill-area transactions to derive representative cost factors.

Because the data collection and analysis focus on a limited set of land sales transactions, we collected sales records as far back as 1999, in order to generate a workable number of observations. **Figure 3** shows price per acre by sale date for the 40 fee title transactions. The earliest fee title transactions were in the range of \$15,000 to \$20,000 per acre (pasture land near Gilroy and wetlands near Guadalupe Slough). Through 2004, most sales averaged under \$10,000 per acre. After 2004, there are some large spikes in the average price. From mid-2007 onwards, prices were more likely to be in the range of \$5,000 to \$10,000 per acre.

These types of land sales transactions are not as predictable as those of the more standardized market for land that has some future development potential. Each sale is idiosyncratic, and there is a substantial range of variation. In recognition of this inherent volatility, we determined that all of the transactions going back to 1999 provided a valid basis for developing average cost factors for the Santa Clara Valley Habitat Plan.

**Table 1** summarizes the characteristics of the fee title transactions, by location and parcel size. Where there are enough observations by category, the table presents the statistics that were used to develop the average cost factors. There are outliers in many of the cells. Analyzing the weighted average sale price (total transaction value divided by total acres), instead of the simple average, reduces the bias introduced by the outliers when the number of observations is small. The table also presents the resultant land cost assumptions for each cell.

**Table 1**  
**Land Transactions Data Summarized by Location and Parcel Size Category**

	Less than 50 acres	50 - 250 acres	Over 250 acres	Total All Parcels

<b>SCV Habitat Plan Assumption</b>	<b>\$34,000</b>	<b>\$17,000</b>	<b>\$16,000</b>	
<b>Total all Areas</b>				
Number of observations	10	17	15	42
Mean (weighted by parcel size)	\$15,181	\$8,850	\$7,387	\$7,908
Median	\$10,525	\$6,757	\$8,879	\$8,129
Minimum/Maximum	\$3,535 / \$34,316	\$2,904 / \$27,714	\$1,800 / \$19,594	\$1,800 / \$34,316

Note: Fee title transactions only. Transactions for parcels that straddle more than one location appear as an observation in each location.  
SOURCE: Smith & Associates and Hausrath Economics Group.

The average price per acre ranges from a low of \$1,800 per acre for 2,900 acres of ranchland in the Remote East Hills (transaction completed in May 2006) to a high of \$34,300 per acre for just

under 50 acres of row crop land near Gilroy (transaction completed in September 2005). In most locations with multiple transactions, the sales prices analyzed range from about \$3,000 per acre up to \$15,000, \$20,000 and \$30,000 per acre.

Generally, the lower average prices are associated with larger parcels. Considering all locations, the weighted average price per acre for large parcels over 250 acres in size is one half the price of parcels less than 50 acres in size.

Agricultural use value is evident in the distinctions between Valley and Hill locations. The range of prices is generally similar among the Hill locations, with parcel size being the distinguishing feature.

**Table 2** summarizes the average cost factors developed based on analysis of these transactions.

**Table 2**  
**Proposed Land Acquisition Cost Assumptions, by location and parcel size**  
**(fee title purchase price per acre in 2010 dollars)**

<b>Location</b>	<b>Less than 50 acres</b>	<b>50 - 250 acres</b>	<b>Over 250 acres</b>
Near East Hills	\$28,000	\$9,000	\$8,000
Near West Hills	\$28,000	\$9,000	\$8,000
Remote East Hills	\$10,000	\$9,000	\$6,000
Remote West Hills	\$10,000	\$9,000	\$6,000
Almaden Valley / Valley Floor	\$34,000	\$17,000	\$16,000

The assumptions range from a low of \$6,000 per acre for parcels over 250 acres in the Remote East and West Hills. The highest price per acre (\$34,000) is assumed for parcels less than 50 acres in the Almaden Valley and Valley Floor locations.

The expected pattern of land acquisition by location and parcel size affects the overall cost of land acquisition over the permit term. **Table 3** shows the proposed land acquisition pattern.

**Table 3**  
**Acres by Location and Parcel Size, May 2012 Habitat Plan**

<b>Location</b>	<b>Less than 50 acres</b>	<b>50 - 250 acres</b>	<b>Over 250 acres</b>	<b>Total</b>	<b>Percent of Total by Location</b>
Near East Hills	300	2,290	6,180	<b>8,770</b>	<b>24%</b>
Near West Hills	270	640	2,850	<b>3,760</b>	<b>10%</b>
Remote East Hills	20	1,920	9,740	<b>11,680</b>	<b>32%</b>
Remote West Hills	10	820	9,350	<b>10,180</b>	<b>28%</b>
Almaden Valley/Valley Floor	80	390	1,240	<b>1,710</b>	<b>5%</b>
<b>Total</b>	<b>680</b>	<b>6,060</b>	<b>29,360</b>	<b>36,100</b>	<b>100%</b>
<b>Percent of Total by Parcel Size</b>	<b>2%</b>	<b>17%</b>	<b>81%</b>	<b>100%</b>	
NOTE: Input by location and parcel size from SCV HCP/NCCP database. The number of acres acquired is greater than the Reserve Area Managed because the Plan also includes requirements (e.g., connectivity, protection of plant occurrences) that will result in additional acquisitions and because parcels purchased to meet a specific requirement will include additional acres of non-target land cover types.					

Four out of every five acres are assumed to be acquired in large parcels of over 250 acres. More than half (60 percent) of the acres are expected to be acquired in the Remote Hills. Combining this land acquisition pattern with the assumed land cost factors by location and parcel size results in the overall estimate of land acquisition cost. For the May 2012 Habitat Plan, *assuming 100 percent fee title transactions*, the average land acquisition cost per acre acquired would be about \$8,100 per acre. With easement assumptions (50 percent of Remote East Hills and Remote West Hills acres acquired with easements, and easement prices representing 80 percent of fee title value on average), the average land acquisition cost per acre is reduced to \$7,400 per acre.

**FIGURE 1**

**TEMPLATE NOTES:**

- *This template is prepared for use on privately-owned fee lands. Certain of the provisions below will likely require modification for conservation easements covering Permittee- or other public entity- owned properties (i.e. management plan, recreational uses, and condemnation provisions.)*
- *Consistent with the Habitat Plan, this template assumes the Implementing Entity will hold the conservation easements over privately-owned fee lands. Italicized bracketed language is included below for insertion in conservation easements the Implementing Entity determines will be held by another nonprofit organization, as allowed in the Habitat Plan.*
- *This template does not identify recreational/public access as allowable uses. Additional provisions (i.e. specific restrictions and allowed uses, as well as reference to “recreation plan” contemplated by SVHCP) would need to be included if any recreational uses are contemplated for the Easement Area/Property [use Easement Area or Property, as applicable depending on whether part or all of a legal parcel is being committed to the reserve area, selection made in Recital A].*
- *This template also assumes the Implementing Entity, and not the Landowner, will conduct the management and monitoring activities set forth in the Management Plan.*

**CONSERVATION EASEMENT AGREEMENT**

THIS CONSERVATION EASEMENT AGREEMENT (the “**Agreement**”) is made this \_\_\_\_\_ day of \_\_\_\_\_, 20\_\_, by and between [insert full legal name of landowner] (“**Landowner**”), and [Santa Clara Valley Habitat Agency, a California Joint Powers Authority] (“**Easement Holder**”). Landowner and Easement Holder are also referred to herein individually as a “**Party**” and collectively as the “**Parties**.”

**RECITALS**

A. Landowner is the [insert description of ownership interest] of certain real property

Santa Clara Valley Habitat Plan –Conservation Easement Template

Draft Date: May 26, 2012

OSA FINAL

FINAL

containing approximately \_\_\_\_\_ acres, located in the County of Santa Clara, State of California, more particularly described in **Exhibit A** attached hereto and incorporated herein by this reference (the “**Property**”) and depicted on the map attached hereto as **Exhibit B** and incorporated herein by reference.

**OR**

A. Landowner is the *[insert description of ownership interest]* of certain real Property located in the County of Santa Clara, State of California, more particularly known as Assessor’s Parcel Number(s) XXXXXX. Landowner intends to grant this Conservation Easement over approximately xx acres of the Property (the “**Easement Area**”), as described in **Exhibit A** attached hereto and incorporated herein by this reference and depicted on the map attached hereto as **Exhibit B** and incorporated herein by reference.

B. This Agreement is being executed and delivered to satisfy certain habitat conservation requirements set forth in the following documents (collectively, the “**Habitat Plan Instruments**”):

(i) The Santa Clara Valley Habitat Plan (“**Habitat Plan**”), dated \_\_\_\_\_, prepared by County of Santa Clara County (“**County**”), City of San Jose (“**San Jose**”), City of Gilroy (“**Gilroy**”), City of Morgan Hill (“**Morgan Hill**”), Santa Clara Valley Water District (“**Water District**”), and Santa Clara Valley Transportation Authority (“**VTA**”), and approved by the United States Fish and Wildlife Service (“**USFWS**”) under Section 10 of the federal Endangered Species Act of 1973 (16 U.S.C. Section 1531 *et seq.*, as it may be amended from time to time) (“**ESA**”), and by California Department of Fish and Game (“**CDFG**”) under the California Natural Community Conservation Planning Act (California Fish and Game Code Section 2800 *et seq.*, as it may be amended from time to time) (“**NCCPA**”); and

(ii) Implementing Agreement for the Santa Clara Valley Habitat Plan (the “**Implementing Agreement**”), dated \_\_\_\_\_, by and among USFWS and CDFG (collectively, the “**Wildlife Agencies**”), Santa Clara Valley Habitat Plan Implementing Agency, a Joint Powers Authority (“**JPA**” or “**Implementing Entity**”), County, San Jose, Gilroy, Morgan Hill, Water District, and VTA (collectively, JPA, County, San Jose, Gilroy, Morgan Hill, Water District, VTA, are referred to herein as “**Permittees**”); and

(iii) The federal incidental take permit issued by USFWS to Permittees for the Habitat Plan pursuant to Section 10 of ESA; and

(iv) The state incidental take permit issued by CDFG to Permittees for the Habitat Plan pursuant to the NCCPA.

FINAL

C. CDFG has jurisdiction, pursuant to Fish and Game Code Section 1802, over the conservation, protection, and management of fish, wildlife, native plants and the habitat necessary for biologically sustainable populations of those species, and CDFG is authorized to hold easements for these purposes pursuant to Civil Code Section 815.3, Fish and Game Code Section 1348, and other provisions of California law.

D. USFWS is an agency of the United States Department of the Interior and is authorized by Federal law to be a third party beneficiary of the Conservation Easement and to administer the Federal Endangered Species Act, 16 U.S.C. § 1531, et seq. (“ESA”), the Fish and Wildlife Coordination Act, 16 U.S.C. §§ 661-666c, and the Fish and Wildlife Act of 1956, 16 U.S.C. § 742(f), et seq.

E. The Easement Holder is a California joint powers authority, and authorized to hold conservation easements pursuant to, among other provisions of law, California Civil Code Section 815.3.

F. In addition to serving as the holder of the conservation easement interest created under this Agreement, JPA also serves as the “Implementing Entity” of the Habitat Plan, and as such, is responsible for overseeing implementation of the Habitat Plan Instruments, including carrying out planning and design, habitat restoration, monitoring, adaptive management programs, and periodic coordination with USFWS and CDFG. *[When used herein, the term “Implementing Entity” refers to the JPA acting in its capacity as the Implementing Entity under the Habitat Plan and the Implementing Agreement, which confer separate rights and obligations on JPA that will survive any future transfer of the Conservation Easement by JPA. In contrast, the term “Easement Holder” is used herein to refer to JPA as the initial holder of such conservation easement interest, as well as any other qualified successor or assignee to which this conservation easement interest has been transferred in accordance with the terms and conditions set forth below.] [TEMPLATE NOTE: The italicized language above will require revision if JPA is not the Easement Holder.]*

G. The *Easement Area/Property* possesses wildlife, habitat values, and associated open space values that are of great importance to Easement Holder, the people of Santa Clara County and the people of the State of California and of the United States (the “**Conservation Values**”). The **Initial Conservation Values**, described in **Exhibit C** attached hereto and incorporated herein by reference, are those Conservation Values that are identified in the Habitat Plan and present on the Easement Area/Property at the time of the execution of the Agreement.

H. Following recordation of this Agreement, the *Easement Area/Property* will be incorporated into the Reserve System (as such term is defined in the Habitat Plan) (“**Reserve System**”) and will count toward the land acquisition requirements set forth in the Habitat Plan.

I. The Implementing Entity *[has developed] [will develop]* a management plan, known as “\_\_\_\_\_,” that applies to the *Easement Area/Property* (the “**Management Plan**”). The Management Plan *[has been] [will be]* developed in accordance with the applicable requirements of the Habitat Plan Instruments *[and [identify any applicable reserve unit management*

FINAL

plans]].

J. The Management Plan *[is] [upon completion, will be]* incorporated herein by reference. Landowner and Easement Holder recognize that changes (e.g., in weather cycles, natural resource management technologies, conservation practices) may dictate an adaptation in the management of the *Easement Area/Property*, consistent with the purposes of this Conservation Easement and the Habitat Plan Instruments. It may be revised from time to time with the written approval of the Landowner, Easement Holder and the Wildlife Agencies, so long as the revisions are consistent with the requirements of the Habitat Plan Instruments *[and [identify applicable reserve unit management plans]]*. A full and complete copy of the current Management Plan, including any such revisions, shall be kept on file at the offices of the Implementing Entity. *[Include if the Management Plan has not been developed as of the effective date of the agreement: The Easement Area/Property will be managed in accordance with the applicable requirements of the Habitat Plan until the Management Plan is developed.]*

K. The State of California recognizes the public importance and validity of conservation easements by enactment of California Civil Code Section 815 *et seq.*

## AGREEMENTS

NOW, THEREFORE, in consideration of the above and mutual covenants, terms, conditions and restrictions contained herein, and for other good and valuable consideration, the receipt and sufficiency of which are hereby acknowledged, and pursuant to the laws of the State of California, including California Civil Code Section 815 *et seq.*, Landowner hereby voluntarily grants and conveys to Easement Holder, its successors and assigns, a conservation easement in gross forever in, on, over and across the Easement Area/Property described in Exhibit A and depicted on Exhibit B (the “**Conservation Easement**”), subject to the terms and conditions set forth herein, restricting forever the uses which may be made of the Easement Area/Property, and the parties agree as follows:

1. **Purpose.** The purpose of this Conservation Easement is to ensure that existing and future natural values and associated wildlife and habitat values of the *Easement Area/Property* will be forever protected by preventing any use of the *Easement Area/Property* that would impair or interfere with the Conservation Values. Landowner intends that this Conservation Easement will confine the use of the *Easement Area/Property* to such activities that are consistent with the purposes set forth herein, including, without limitation, those involving the preservation, restoration, and enhancement of the *Easement Area/Property*’s Covered Species and their habitats.

2. **Baseline Documentation Report.** The parties acknowledge that a Baseline Documentation Report (the “**Report**”) has been prepared for the *Easement Area/Property* and approved in writing by Landowner and Easement Holder. A copy of the Report is on file with Landowner and Easement Holder at their respective addresses for notices set forth below. The parties agree that the Report contains an accurate representation of the biological and physical condition of the *Easement Area/Property* at the time this Agreement is recorded in the Official Records of Santa Clara County (“**Official Records**”), including a full inventory of all of the

Santa Clara Valley Habitat Plan –Conservation Easement Template

Draft Date: May 26, 2012

OSA FINAL

*Easement Area/Property's* Covered Species and natural communities found thereon.

Notwithstanding the foregoing, if a controversy arises with respect to the nature and extent of the physical or biological condition of the *Easement Area/Property* or the allowed uses of the *Easement Area/Property*, the parties shall not be foreclosed from utilizing any and all other relevant documents, surveys or other evidence or information to assist in the resolution of the controversy.

3. **Rights of Easement Holder.** To accomplish the purposes of this Conservation Easement, Landowner hereby grants and conveys the following rights to Easement Holder:

(a) To preserve, protect, sustain, restore, and enhance the Conservation Values for the *Easement Area/Property* described in **Exhibit C** or which develop on the *Easement Area/Property* in accordance with the Management Plan and the terms and conditions of this Conservation Easement;

(b) To enter upon the *Easement Area/Property* to monitor Landowner's compliance with, and to otherwise enforce the terms of, this Conservation Easement, and for scientific research necessary to support monitoring and in order to support adaptive management of the Conservation Values; *provided*, that Easement Holder shall not unreasonably interfere with Landowner's allowed uses and quiet enjoyment of the *Easement Area/Property*;

(c) To enter upon the *Easement Area/Property* to carry out, at Easement Holder's sole cost and expense, those management and monitoring requirements applicable to the Easement Area/Property that are set forth in the Management Plan and in Habitat Plan Chapters 5 and 7, *[including, without limitation, installation and maintenance of fencing around the perimeter of the Easement Area/Property to the extent referenced in the Management Plan as necessary to protect the Conservation Values;]* *provided*, that Easement Holder shall use reasonable good faith efforts to conduct such management and monitoring activities in a manner that does not unreasonably interfere with Landowner's allowed uses and quiet enjoyment of the *Easement Area/Property*;

(d) To prevent any activity on or use of the Easement Area/Property that is inconsistent with the purposes of this Conservation Easement and to require the restoration of such areas or features of the Easement Area/Property that may be damaged by any act, failure to act, or any use that is inconsistent with the purposes of this Conservation Easement;

(e) To require that all mineral, air and water rights held by Landowner that Easement Holder deems necessary to preserve, protect and sustain the biological resources and Conservation Values of the *Easement Area/Property* shall remain a part of and be put to beneficial use upon the *Easement Area/Property*, consistent with the purposes of this Conservation Easement; and

(f) All present and future development rights and wind power rights allocated, implied, reserved or inherent in the *Easement Area/Property*; such rights are hereby

terminated and extinguished, and may not be used on or transferred to any portion of the Property. Landowner understands and agrees that nothing in this Conservation Easement relieves Landowner of any obligation or restriction in relation to the development or use of the *Easement Area/Property* imposed by law, including but not limited to local land use restrictions.

Except where there is an imminent threat to the *Easement Area/Property* or its Conservation Values, Easement Holder and its employees, contractors or agents will only enter the Easement Area/Property at reasonable times and with at least forty-eight (48) hours advance notice to Landowner. The Landowner may waive these requirements in whole or in part by written notice to Easement Holder.

4. **Prohibited Uses.** Any activity on or use of the *Easement Area/Property* that adversely affects the purposes of this Conservation Easement is prohibited. Without limiting the generality of the foregoing, Landowner, Landowner's personal representatives, heirs, successors, assigns, employees, agents, lessees, licensees and invitees are expressly prohibited from doing or allowing any of the following uses and activities on the *Easement Area/Property*, unless, and then only to the extent that, a generally prohibited activity set forth below is: (i) an allowed use or practice (e.g., agricultural, rangeland or recreational uses) set forth on **Exhibit D** attached hereto and incorporated herein by reference; (ii) a management practice set forth in the Management Plan, (iii) necessary in connection with the performance of any of the conservation actions described in Habitat Plan Chapter 5; or (iv) otherwise necessary to maintain or enhance the Conservation Values:

- (a) Unseasonal watering;
- (b) Use of fertilizers, pesticides, biocides, herbicides or other chemicals;
- (c) Use of off-road vehicles and use of any other motorized vehicles except on existing roadways, excepting off-road vehicle use required to conduct any allowed management practice set forth in the Management Plan;
- (d) Any construction, reconstruction, relocation or placement of any road, building, billboard, fencing, or sign, or any other structure or improvement of any kind, or altering the surface or general topography of the *Easement Area/Property* without written approval by the Easement Holder and Wildlife Agencies unless otherwise allowed in the Management Plan;
- (e) Agricultural uses, including, without limitation, vineyards, nurseries, or intensive livestock use (e.g., dairy, feedlot) except as may be provided for in the Management Plan (e.g., prescribed grazing);
- (f) Any legal or de facto division, subdivision or partitioning of the *Easement Area/Property* or any fee transfer of less than the entire Easement Area/Property;

- (g) Depositing or accumulation of soil, trash, ashes, refuse, waste, bio-solids or any other materials;
- (h) Planting, introduction, or dispersal of nonnative plant or animal species;
- (i) Filling, dumping, excavating, draining, dredging, mining, drilling, removing, or exploring for or extraction of minerals, loam, soil, sands, gravel, rocks, or other material on or below the surface of the *Easement Area/Property*, and granting or authorizing any surface entry for any of these purposes;
- (j) Removing, destroying, or cutting of trees, shrubs, or other vegetation;
- (k) Manipulating, impounding, or altering any water course, body of water, or water circulation on the *Easement Area/Property*, and activities or uses detrimental to water quality, including but not limited to degradation or pollution of any surface or subsurface waters; and
- (l) Without the prior written consent of Easement Holder, which Easement Holder may reasonably withhold, transferring, encumbering, selling, leasing or otherwise separating the mineral, air or water rights for the *Easement Area/Property* owned by Landowner; changing the place or purpose of use of the water rights owned by Landowner; abandoning or allowing the abandonment of, by action or inaction, any water or water rights, ditch or ditch rights, spring rights, reservoir or storage rights, wells, ground water rights or other rights in and to the use of water historically used on or otherwise appurtenant to the *Easement Area/Property* that are owned by Landowner, including but not limited to: (i) riparian water rights; (ii) appropriative water rights; (iii) rights to waters which are secured under contract with any irrigation or water district, to the extent such waters are customarily applied to the *Easement Area/Property*; and (iv) any water from wells that are in existence or may be constructed in the future on the *Easement Area/Property*.

***[TEMPLATE NOTE: Section 4 “Prohibited Uses” for any Conservation Easement may include additional prohibited uses, or refinements of the above, to address specific site conditions, Landowner preferences and operations, and species and habitat needs, as contemplated by Habitat Plan Section 8.6.3 and approved by the Easement Holder and the Wildlife Agencies. Additionally, this prohibited uses section may require modification to address public access and recreation uses to the extent contemplated or required at the Easement Area/Property under the Management Plan.]***

5. **Unlawful Entry.** Landowner shall undertake all reasonable actions to prevent the unlawful entry and trespass on the *Easement Area/Property* by persons whose uses or activities may degrade or harm the Conservation Values or are otherwise inconsistent with the purposes of this Conservation Easement.

6. **Landowner's Reserved Rights; Allowed Uses.** Landowner reserves to itself, and to its personal representatives, heirs, successors, and assigns, all rights accruing from its ownership of the *Easement Area/Property*, including without limitation, the following (collectively, the “**Allowed Uses**”): (a) those specific uses and activities identified in the Management Plan(s) or detailed in **Exhibit D** attached hereto, and (b) all other uses of the *Easement Area/Property* that are not expressly prohibited or limited by this Agreement, and are consistent with the purposes of this Conservation Easement as set forth in Section 1. Landowner shall have the right to exercise any of the Allowed Uses directly or to allow or invite others to engage in any of the Allowed Uses. While Landowner is not obligated under this Agreement to perform the management and monitoring actions set forth in the Management Plan(s), Landowner's exercise of the Allowed Uses shall be conducted in a manner that is consistent with the Management Plan(s) and Conservation Values.

7. **Easement Holder's Remedies.** If Easement Holder or any Third-Party Beneficiary (as defined in **Section 7(d)** below) determines there is a violation of the terms of this Agreement or that such violation is threatened, written notice of such violation and a demand for corrective action sufficient to cure the violation shall be given to Landowner, with a copy provided to Easement Holder and each other Third-Party Beneficiary. The notice of violation shall specify the measures the Landowner must take to cure the violation. If Landowner fails to cure the violation within thirty (30) days after receipt of written notice and demand from Easement Holder or any Third-Party Beneficiary, as applicable; or if the cure reasonably requires more than thirty (30) days to complete and Landowner fails to begin the cure within such thirty (30) day period; or Landowner fails to continue diligently to complete the cure, Easement Holder or any Third-Party Beneficiary may bring an action at law or in equity in a court of competent jurisdiction to enforce the terms of this Agreement, to recover any damages to which Easement Holder and the Third-Party Beneficiaries may be entitled for violation of the terms of this Agreement or for any injury to the Conservation Values, to enjoin the violation, *ex parte* as necessary, by temporary or permanent injunction without the necessity of proving either actual damages or the inadequacy of otherwise available legal remedies, or for other equitable relief, including, but not limited to, the restoration of the *Easement Area/Property* to the condition in which it existed prior to any such violation or injury. Without limiting Landowner's liability therefor, any damages recovered may be applied to the cost of undertaking any corrective action on the *Easement Area/Property* at the election of the party receiving such damages.

If Easement Holder or any Third-Party Beneficiary, each in its sole discretion, determines that circumstances require immediate action to prevent or mitigate damage to the Conservation Values, Easement Holder and/or any Third-Party Beneficiary may pursue its remedies under this section without prior notice to Landowner or without waiting for the period provided for cure to expire. The rights of Easement Holder and the Third-Party Beneficiaries under this section apply equally to actual or threatened violations of the terms of this Agreement. Landowner agrees that Easement Holder's and Third-Party Beneficiaries' remedies at law for any violation of the terms of this Agreement are inadequate and that Easement Holder and/or any Third-Party Beneficiary shall be entitled to the injunctive relief described in this section, both prohibitive and mandatory, in addition to such other relief to which Easement Holder and the Third-Party Beneficiaries may be entitled, including specific performance of the terms of this Agreement, without the necessity of

proving either actual damages or the inadequacy of otherwise available legal remedies. Remedies described in this section shall be cumulative and shall be in addition to all remedies now or hereafter existing at law or in equity, including but not limited to, the remedies set forth in California Civil Code Section 815, *et seq.* The failure of Easement Holder or any Third-Party Beneficiary to discover a violation or to take immediate legal action in response to such action shall not bar such party from taking legal action at a later time.

(a) **Costs of Enforcement.** Any reasonable costs incurred by the Easement Holder or any Third Party Beneficiary, where it is the prevailing party, in enforcing the terms of this Conservation Easement against the Landowner, including, but not limited to, costs of suit and attorneys' and experts' fees, and any costs of restoration necessitated by Landowner's negligence or breach of this Agreement shall be borne by Landowner. In any action where an agency of the United States is a party, the right to recover fees and costs shall be governed by federal law.

(b) **Enforcement Discretion.** Enforcement of the terms of this Agreement against Landowner shall be at the respective discretion of Easement Holder and each of the Third-Party Beneficiaries, and any forbearance by any such party to exercise its rights under this Agreement in the event of any breach of any term of this Agreement shall not be deemed or construed to be a waiver by such party of such term or of any subsequent breach of the same or any other term of this Agreement or of any of such party's rights under this Agreement. No delay or omission by Easement Holder or any Third-Party Beneficiary in the exercise of any right or remedy upon any breach shall impair such right or remedy or be construed as a waiver.

(c) **Acts Beyond Landowner's Control.** Nothing contained in this Agreement shall be construed to, or shall entitle, Easement Holder or any Third-Party Beneficiary to bring any action against Landowner for any injury to or change in the *Easement Area/Property* resulting from (i) any natural cause beyond Landowner's control, including, but not limited to, climate change, fire not caused by Landowner, flood, storm, and earth movement, or any prudent action taken by Landowner under emergency conditions to prevent, abate, or mitigate significant injury to the *Easement Area/Property* resulting from such causes; (ii) acts by Easement Holder or any Third-Party Beneficiary or any of their employees, contractors or agents; or (iii) acts by persons that entered the *Easement Area/Property* unlawfully or by Trespass whose activities degrade or harm the Conservation Values of the *Easement Area/Property* or whose activities are otherwise inconsistent with this Conservation Easement where Landowner has undertaken all reasonable actions to prevent such activities [*for public agencies only: or (iii) acts by persons that entered the Easement Area/Property lawfully or unlawfully whose activities degrade or harm the Conservation Values of the Easement Area/Property or whose activities are otherwise inconsistent with this Conservation Easement where Landowner has undertaken all reasonable actions to discourage or prevent such activities*].

(d) **Third Party Beneficiary Rights.** The parties intend for each of Implementing Entity (during any such period, if any, that Implementing Entity does not also constitute Easement Holder), USFWS and CDFG (collectively, **“Third-Party Beneficiaries”**) to be a third-party beneficiary of this Agreement. All rights and remedies conveyed to Easement Holder under this Agreement shall extend to and are enforceable by each of the Third-Party Beneficiaries in accordance with the terms hereof. Landowner and Easement Holder acknowledge that, as third party beneficiaries of this Conservation Easement, the Third-Party Beneficiaries shall have the same rights of access to the *Easement Area/Property* granted to Easement Holder in **Section 3** above, and with rights to enforce all of the provisions of this Agreement. If at any time in the future Landowner uses, allows the use, or threatens to use or allow use of, the *Easement Area/Property* for any purpose that is inconsistent with or in violation of this Agreement then, despite the provisions of California Civil Code Section 815.7, the California Attorney General and each Third-Party Beneficiary has standing as an interested party in any proceeding affecting the Conservation Easement. These rights are in addition to, and do not limit, the rights of enforcement under the Habitat Plan Instruments. In addition, if CDFG reasonably determines that the *Easement Area/Property* is not being held, monitored, or stewarded for conservation purposes in the manner specified in this Agreement, the Habitat Plan Instruments, or the Management Plan, the Conservation Easement shall revert to the State of California or another entity as described in California Government Code Section 65967, subdivisions (b) and (c), and subject to approval by CDFG.

8. **Public Access.** Nothing contained in this Agreement gives or grants to the public an independent right to enter upon or use the *Easement Area/Property* or any portion thereof. Nor shall this Agreement extinguish any public right to enter upon or use the *Easement Area/Property*.

9. **Costs and Liabilities.** Except for those specific obligations to be undertaken by Easement Holder under Section 3 above, Landowner shall retain all responsibilities and shall bear all costs and liabilities of any kind related to Landowner’s ownership, operation, management, and maintenance activities on and relating to the *Easement Area/Property*. Landowner agrees that neither the Easement Holder nor Third Party Beneficiaries shall have any duty or responsibility for the operation or maintenance of the *Easement Area/Property*, the monitoring of hazardous conditions thereon, or the protection of Landowner, the public or any third parties from risks relating to conditions on the *Easement Area/Property*. Each of Landowner and Easement Holder shall remain responsible for obtaining any applicable governmental permits and approvals for any of such Party’s activity or use allowed on the *Easement Area/Property* under this Agreement, and each of Landowner and Easement Holder shall undertake all allowed activities and uses of the *Easement Area/Property* in accordance with all applicable federal, state, local and administrative agency statutes, ordinances, rules, regulations, orders and requirements. Landowner shall pay before delinquency all taxes, assessments, fees, and charges of whatever description levied on or assessed against the *Easement Area/Property* by competent authority (collectively **“taxes”**), including any taxes imposed upon, or incurred as a result of, this Agreement, and shall furnish Easement Holder with satisfactory evidence of payment upon request. Landowner and Easement Holder shall keep the *Easement Area/Property* free from any liens, including those arising out of any obligations incurred

by such Party for any labor or materials furnished or alleged to have been furnished to or for such Party at or for use on the *Easement Area/Property*.

10. **Indemnification.**

(a) **Indemnification by Landowner.** Landowner shall hold harmless, protect and indemnify Easement Holder and the Third-Party Beneficiaries, and their respective members, directors, officers, employees, agents, contractors, and representatives and the heirs, personal representatives, successors and assigns of each of them (each a **“Landowner Indemnified Party”** and, collectively, the **“Landowner Indemnified Parties”**) from and against any and all liabilities, penalties, costs, losses, damages, expenses (including, without limitation, reasonable attorneys' and experts' fees and costs), causes of action, claims, demands, orders, liens or judgments (each a **“Claim”** and, collectively, **“Claims”**), arising from or in any way connected with: (i) the activities of Landowner on the *Easement Area/Property*; (ii) the inaccuracy of any representation or warranty made by Landowner in this Agreement; (iii) the breach by Landowner of any provision of this Agreement; (iv) any injury to or the death of any person, or physical damage to any *Easement Area/Property* resulting from any act, omission, condition, or other matter related to or occurring on or about the *Easement Area/Property*, unless such injury or death or physical damage to any *Easement Area/Property* relates to an activity on, or use of, the *Easement Area/Property* by Easement Holder, including without limitation, those activities performed under the Management Plan, or negligent or willful misconduct of the Landowner Indemnified Party; or (v) any violation of, or failure to comply with, any state, federal or local law, regulation or requirement, by Landowner, or by any entity, other than one of the Landowner Indemnified Parties, acting at the time upon permission from Landowner, in any way affecting, involving or relating to the *Easement Area/Property*. If any action or proceeding is brought against any of the Landowner Indemnified Parties by reason of any such Claim, Landowner shall, at the election of and upon written notice from Easement Holder and the Third-Party Beneficiaries, defend such action or proceeding by counsel reasonably acceptable to the Landowner Indemnified Party.

(b) **Indemnification by Easement Holder.** Easement Holder shall hold harmless, protect, and indemnify Landowner and the Third-Party Beneficiaries, and their respective members, directors, officers, employees, agents, contractors, and representatives and the heirs, personal representatives, successors and assigns of each of them (each, an **“Easement Holder Indemnified Party,”** and collectively, the **“Easement Holder Indemnified Parties”**) from and against any and all Claims arising from or in any way connected with: (a) the activities of Easement Holder on the *Easement Area/Property*, including without limitation the Easement Holder's performance of management and monitoring activities set forth in the Management Plan; (b) breach by Easement Holder of any provision of this Agreement; (c) any injury to or the death of any person, or physical damage to any *Easement Area/Property* occurring on or about the *Easement Area/Property* resulting from any act, omission, condition, or other matter related to, an activity on, or use of, the *Easement Area/Property* by Easement Holder, including without limitation, those

performed under the Management Plan, unless due solely to the negligence or willful misconduct of the Easement Holder Indemnified Party; and (d) any violation of, or failure to comply with, any state, federal or local law, regulation or requirement, by Easement Holder in any way affecting, involving or relating to the *Easement Area/Property*. If any action or proceeding is brought against any of the Easement Holder Indemnified Parties by reason of any such Claim, Easement Holder shall, at the election of and upon written notice from Landowner, defend such action or proceeding by counsel reasonably acceptable to the Easement Holder Indemnified Party.

11. **Extinguishment.** The Conservation Easement created by this Agreement constitutes a property right. It is the Parties' intention that the terms and conditions of this Agreement shall be carried out in perpetuity. Liberal construction is expressly required for purposes of effectuating the Conservation Easement in perpetuity, notwithstanding economic hardship or changed conditions of any kind. If circumstances arise in the future that render the purposes of this Agreement impossible to accomplish, this Agreement can only be terminated or extinguished, in whole or in part, by judicial proceedings in a court of competent jurisdiction. In addition, no such extinguishment shall affect the value of Easement Holder's interest in the *Easement Area/Property*, and if the *Easement Area/Property*, or any interest therein, is sold, exchanged or taken by power of eminent domain after such extinguishment, Easement Holder shall be entitled to receive the fair market value of the Conservation Easement at the time of such extinguishment. If such extinguishment occurs with respect to fewer than all acres of the *Easement Area/Property*, the amounts described above shall be calculated based on the actual number of acres subject to extinguishment.

12. **Condemnation.** The purposes of this Conservation Easement are presumed to be the best and most necessary public use as defined in California Code of Civil Procedure Section 1240.680 notwithstanding Code of Civil Procedure Sections 1240.690 and 1240.700. *[TEMPLATE NOTE: If Easement Holder is CDFG or another state agency, substitute the preceding sentence with the following: This Conservation Easement is a "wildlife conservation easement" acquired by an agency of the State of California, the condemnation of which is prohibited except as provided in California Fish and Game Code Section 1348.3.]*

13. **Transfer of Conservation Easement.** This Agreement may be transferred by Easement Holder upon written approval of the Third-Party Beneficiaries, which approval shall not be unreasonably withheld or delayed; provided, that Easement Holder shall give the Third-Party Beneficiaries at least sixty (60) calendar days prior written notice of the proposed assignment or transfer. Easement Holder may transfer its rights under this Agreement only to an entity or organization: (a) authorized to acquire and hold conservation easements pursuant to California Civil Code Section 815.3 and California Government Code Section 65967(c) (and any successor or other provisions then applicable), or the laws of the United States; and (b) otherwise reasonably acceptable to the Third-Party Beneficiaries. Easement Holder shall require the transferee to record the conveyance in the Official Records of the County where the *Easement Area/Property* is located. The failure of Easement Holder to perform any act provided in this section shall not impair the validity of this Agreement or limit its enforcement in any way. Any transfer under this section shall be subject to the requirements of **Section 17** below.

14. **Transfer of Easement Area/Property.** Landowner agrees to incorporate the terms of this Agreement by reference in any deed or other legal instrument by which Landowner divests itself of any interest in all or any portion of the *Easement Area/Property*, including, without limitation, a leasehold interest. Landowner further agrees to give written notice to Easement Holder and the Third-Party Beneficiaries of the intent to transfer any interest at least thirty (30) calendar days prior to the date of such transfer. Easement Holder and the Third-Party Beneficiaries shall have the right to prevent subsequent transfers in which prospective subsequent claimants or transferees are not given notice of the covenants, terms, conditions and restrictions of this Agreement. The failure of Landowner to perform any act provided in this section shall not impair the validity of this Agreement or limit its enforceability in any way. Any successor in interest of Landowner, by acceptance of a deed, lease, or other document purporting to convey an interest in the *Easement Area/Property*, shall be deemed to have consented to, reaffirmed and agreed to be bound by all of the terms, covenants, restrictions, and conditions of this Agreement.

15. **Notices.** Any notice, demand, request, consent, approval, or communication that Landowner, Easement Holder, or any Third-Party Beneficiary desires or is required to give to the others shall be in writing and be served personally or sent by recognized overnight courier that guarantees next-day delivery or by first class mail, postage fully prepaid, addressed as follows:

or to such other address as a party shall designate by written notice to the others. Notice shall be deemed effective upon delivery in the case of personal delivery or delivery by overnight courier or, in the case of delivery by first class mail, five (5) calendar days after deposit into the United States mail.

16. **Amendment.** This Agreement may not be amended, modified or otherwise changed in any manner, except by a written amendment executed by the parties hereto, or their successors in interest, it being understood that no easement holder or landowner will ever be obligated to negotiate or enter into any such amendment; and no discretionary approval that this Agreement may allow to be made from time to time by a party will operate to amend or modify any of the terms of this Agreement to any extent or in any manner. Any such amendment shall be subject to the prior written consent of the Third-Party Beneficiaries; any amendment made without such consent is void and without effect. Any such amendment shall be consistent with the purposes of the Conservation Easement and shall not affect the perpetual duration of the Conservation Easement. Any such amendment must refer to this Agreement by reference to its recordation data, and must be recorded in the Official Records of the County where the *Easement Area/Property* is located.

17. **Merger.** The doctrine of merger shall not operate to extinguish the Conservation Easement if the Conservation Easement and the *Easement Area/Property* become vested in the same party. If, despite this intent, the doctrine of merger applies to extinguish the Conservation Easement then, a replacement conservation easement, with a new Easement Holder identified by the Implementing Entity and approved by the Third-Party Beneficiaries, containing the same protections embodied in this Agreement shall be recorded against the *Easement Area/Property*.

18. **No Hazardous Materials Liability.** Landowner represents and warrants that, after reasonable review of Landowner's records as of the date of this Agreement, Landowner has no knowledge or notice of any Hazardous Materials (as defined below) or underground storage tanks existing, generated, treated, stored, used, released, disposed of, deposited or abandoned in, on, under, or from the *Easement Area/Property*, or transported to or from or affecting the *Easement Area/Property* [except as disclosed in the Report]. [Insert site-specific conditions, if applicable.] Landowner further represents and warrants that Landowner shall comply with all Environmental Laws (as defined below) in using the *Easement Area/Property* and that Landowner shall keep the *Easement Area/Property* free of any material environmental defect, including, without limitation,

Santa Clara Valley Habitat Plan –Conservation Easement Template

OSA FINAL

contamination from Hazardous Materials (as defined below). Without limiting the obligations of Landowner under this Agreement, Landowner hereby releases and agrees to indemnify, protect and hold harmless the Landowner Indemnified Parties (as defined in **Section 10(a)**) from and against any and all Claims (as defined in **Section 10(a)**) arising from or connected with any Hazardous Materials or underground storage tanks present, alleged to be present, or otherwise associated with the *Easement Area/Property* at any time, except any Hazardous Materials placed, disposed or released by Landowner Indemnified Parties, or their employees or agents. This release and indemnification includes, without limitation, Claims for (a) injury to or death of any person or physical damage to any *Easement Area/Property*; and (b) the violation or alleged violation of, or other failure to comply with, any Environmental Laws (as defined below). If any action or proceeding is brought against any of the Landowner Indemnified Parties by reason of any such Claim, Landowner shall, at the election of and upon written notice, defend such action or proceeding by counsel reasonably acceptable to the Landowner Indemnified Party.

Despite any contrary provision of this Agreement, the parties do not intend this Agreement to be, and this Agreement shall not be, construed such that it creates in or gives to Easement Holder or the Third Party Beneficiaries any of the following:

- (a) The obligations or liability of an "Landowner" or "operator," as those terms are defined and used in Environmental Laws (as defined below), including, without limitation, the Comprehensive Environmental Response, Compensation and Liability Act of 1980, as amended (42 U.S.C. Section 9601 *et seq.*; hereinafter, "CERCLA"); or
- (b) The obligations or liabilities of a person described in 42 U.S.C. Section 9607(a)(3) or (4); or
- (c) The obligations of a responsible person under any applicable Environmental Laws; or
- (d) The right to investigate and remediate any Hazardous Materials associated with the *Easement Area/Property*; or
- (e) Any control over Landowner's ability to investigate, remove, remediate or otherwise clean up any Hazardous Materials associated with the *Easement Area/Property*.

The term "**Hazardous Materials**" includes, without limitation, (a) material that is flammable, explosive or radioactive; (b) petroleum products, including by-products and fractions thereof; and (c) hazardous materials, hazardous wastes, hazardous or toxic substances, or related materials defined in CERCLA, the Resource Conservation and Recovery Act of 1976 (42 U.S.C. Section 6901 *et seq.*; hereinafter "**RCRA**"); the Hazardous Materials Transportation Act (49 U.S.C. Section 6901 *et seq.*; hereinafter "**HTA**"); the Hazardous Waste Control Law (California Health & Safety Code Section 25100 *et seq.*; hereinafter "**HCL**"); the Carpenter-Presley-Tanner Hazardous Substance Account Act (California Health & Safety Code Section 25300 *et seq.*; hereinafter "**HAS**"),

and in the regulations adopted and publications promulgated pursuant to them, or any other applicable Environmental Laws now in effect or enacted after the date of this Agreement.

The term “**Environmental Laws**” includes, without limitation, CERCLA, RCRA, HTA, HCL, HSA, and any other federal, state, local or administrative agency statute, ordinance, rule, regulation, order or requirement relating to pollution, protection of human health or safety, the environment or Hazardous Materials.

19. **Representations and Warranties.** Landowner hereby makes the following representations and warranties for the benefit of Easement Holder and the Third-Party Beneficiaries:

(a) **Authority.** Landowner has good and sufficient title to the *Easement Area/Property* (including all appurtenances thereto, including, without limitation, [*all minerals and mineral rights and all water and water rights*], and Landowner has full right and authority to enter into this Agreement and convey the Conservation Easement to Easement Holder. There are no monetary liens and encumbrances recorded against the *Easement Area/Property* except as expressly identified in **Exhibit E**. All deeds of trust and mortgages recorded against the *Easement Area/Property*, or any portion thereof, are and shall continue to be subordinated to this Conservation Easement; documentation of such subordinations are contained in Exhibit E.

(b) **Compliance with Laws.** Landowner has not received notice of, and has no knowledge of, any material violation of any federal, state, county or other governmental or quasi-governmental statute, ordinance, regulation, law or administrative or judicial order with respect to the *Easement Area/Property* [*except as disclosed in the Report*]. [*Insert site-specific conditions, if applicable.*]

(c) **No Litigation.** There is no action, suit or proceeding which is pending or threatened against the *Easement Area/Property* or any portion thereof relating to or arising out of the Landownership or use of the *Easement Area/Property*, or any portion thereof, in any court or in any federal, state, county, or municipal department, commission, board, bureau, agency or other governmental instrumentality.

20. **General Provisions.**

(a) **Controlling Law.** The interpretation and performance of this Agreement shall be governed by the laws of the State of California, disregarding the conflicts of law principles of such state, and by applicable federal law.

(b) **Liberal Construction.** It is the intent of this Agreement to preserve the condition of the *Easement Area/Property* and each of the Conservation Values protected herein, notwithstanding economic or other hardship or changes in circumstances or conditions. The provisions of this Agreement shall be liberally construed to effectuate the purposes of the Conservation Easement and to allow Landowner’s use and enjoyment of the

*Easement Area/Property* to the extent consistent with such purposes. Liberal construction is expressly required for purposes of effectuating this Agreement in perpetuity, notwithstanding changed conditions of any kind. The Conservation Easement created by this Agreement is the intended best and most productive use of the *Easement Area/Property*. No remedy or election given by any provision in this Agreement shall be deemed exclusive unless so indicated, but it shall, wherever possible, be cumulative with all other remedies at law or in equity. The parties acknowledge that each party and its counsel have had the opportunity to review and revise this Agreement and that no rule of construction that ambiguities are to be resolved against the drafting party shall be employed in the interpretation of this Agreement. In the event of any conflict between the provisions of this Agreement and the provisions of any use and zoning restrictions of the State of California, the county in which the *Easement Area/Property* is located, or any other governmental entity with jurisdiction, the more restrictive provisions shall apply. If any provision in this instrument is found to be ambiguous, an interpretation consistent with the purposes of this Agreement that would render the provision valid shall be favored over any interpretation that would render it invalid.

(c) **Severability.** If a court of competent jurisdiction voids or invalidates on its face any provision of this Agreement, such action shall not affect the remainder of this Agreement. If a court of competent jurisdiction voids or invalidates the application of any provision of this Agreement to a person or circumstance, such action shall not affect the application of the provision to other persons or circumstances.

(d) **Entire Agreement.** This instrument sets forth the entire agreement of the parties with respect to this Agreement and supersedes all prior discussions, negotiations, understandings, or agreements relating to this Agreement. No alteration or variation of this instrument shall be valid or binding unless contained in an amendment in accordance with **Section 16.**

(e) **No Forfeiture.** Nothing contained herein will result in a forfeiture or reversion of Landowner's title in any respect.

(f) **Successors.** The covenants, terms, conditions, and restrictions of this Agreement shall be binding upon, and inure to the benefit of, the parties hereto and their respective personal representatives, heirs, successors, and assigns and shall constitute a servitude running in perpetuity with the *Easement Area/Property*.

(g) **Termination of Rights and Obligations.** A party's rights and obligations under this Agreement terminate upon transfer of the party's interest in the Agreement, except that liability for acts or omissions occurring prior to transfer shall survive transfer.

(h) **Captions.** The captions in this instrument have been inserted solely for convenience of reference and are not a part of this instrument and shall have no effect upon its construction or interpretation.

(i) **Additional Easements.** Landowner shall not grant any additional easements, rights of way or other interests in the Property (other than a security interest that is subordinate to this Agreement), or grant or otherwise abandon or relinquish any water right or agreement relating to the Property, without first obtaining the written consent of Easement Holder and the Third-Party Beneficiaries. Easement Holder and the Third-Party Beneficiaries may withhold such consent if it determines that the proposed interest or transfer is inconsistent with the purposes of this Conservation Easement or will impair or interfere with the Conservation Values. This section shall not prohibit transfer of a fee or leasehold interest in the Property that is subject to this Agreement and complies with **Section 14**.

(i) **Recording.** Easement Holder shall record this Agreement in the Official Records of the county where the *Easement Area/Property* is located, and may re-record it at any time as Easement Holder deems necessary to preserve its rights hereunder.

(k) **Counterparts.** The parties may execute this Agreement in two or more counterparts, which shall, in the aggregate, be signed by both parties; each counterpart shall be deemed an original instrument as against any party who has signed it. In the event of any disparity between the counterparts produced, the recorded counterpart shall be controlling.

## Exhibit C

### Initial Conservation Values

*[In accordance with Habitat Plan Section 8.6.3, this Exhibit C will set forth those land-cover types and covered species habitat described in Habitat Plan Chapter 3 that are present on the Easement Area/Property. Section 8.6.3 also requires the Conservation Easement to either include or incorporate by reference the initial pre-acquisition assessment of covered species and natural communities present, so Exhibit C should also be prepared in a way that satisfies this requirement. by either listing covered species and natural communities consistent with those in the pre-acquisition assessment or by including an explicit cross-reference and incorporation by reference to the pre-acquisition assessment. If a complete biological inventory is available, it will be incorporated by reference in this Exhibit C.]*

**PLEASE NOTE: The following sample Agreement is provided for reference. The Department of Fish and Game updates this document as needed, and it does not necessarily contain all provisions appropriate for a given project.**

## **Exhibit D**

### **Allowed Uses**

#### ***Template Notes:***

- ***As contemplated in Habitat Plan Section 8.6.3, this Exhibit D will include a list of specific allowable uses and improvements on the Easement Area/Property that will be developed with the Landowner, customized to protect the nature and resource values of the specific Easement Area/Property while allowing, to the extent practicable, the Landowner's current and future uses of the property***
- ***If the Easement Area/Property is cultivated agricultural land, Habitat Plan Section 8.6.3 requires the conservation easement to describe the agricultural practices to be undertaken to ensure the Easement Area/Property's suitability as foraging and breeding habitat for covered species and/or as landscape linkages for native species, measures to maintain or enhance aquatic or riparian habitat, if present, and how the Easement Area/Property meets the Habitat Plan goals and objectives.***
- ***If the Easement Area/Property is currently grazed or planned to be grazed, Habitat Plan Section 8.6.3 requires the conservation easement to describe the general nature of the grazing to be allowed, specify desired vegetation and other habitat conditions. Specific guidelines or conditions for grazing will be included in the Management Plan. In addition, the following will be included in this Exhibit D:***

*Landowner shall have the right to maintain, repair, reasonably enlarge, and reasonably replace the improvements that exist on the Easement Area/Property and which are acknowledged in this Conservation Easement, in the same or different locations, provided that Landowner shall first obtain Easement Holder's and Wildlife Agencies prior written approval for any enlargement, relocation or replacement. Said approval shall not be unreasonably withheld, conditioned, or delayed but in no event shall that approval be granted if said enlargement or replacement would impair or diminish the Conservation Values of the Easement Area/Property. Notwithstanding the foregoing, (i) maintenance, repair, enlargement and replacement of improvements authorized in the Management Plan may be undertaken without additional Easement Holder or Wildlife Agency approval, and (ii) existing fences may be repaired and replaced for purposes of reasonable and customary management of livestock and wildlife, without further permission of Easement Holder or Wildlife Agencies; provided, all repair, and replacements shall be, designed and installed to protect, and not impair, the Conservation Values of the Easement Area/Property, including, but not limited to, wildlife corridors.*

WATER RESOURCES:

*Landowner may maintain such surface water resources on the Easement Area/Property as are noted in the Report as currently existing on the Easement Area/Property provided that said maintenance is consistent with the terms and conditions of this Conservation Easement and the Management Plan. Landowner may only develop new or enhance existing surface water resources with the prior written approval of Easement Holder and Wildlife Agencies which approval shall not be unreasonably withheld, conditioned, or unreasonably delayed, and then only if said development is necessary for allowed ranching operations or to enhance, restore, create, preserve, or protect the Conservation Values of this Conservation Easement, and the development does not impair the Conservation Values of this Conservation Easement and that such development is consistent with State Water Law]*

Appendix J

## **Monitoring Issues and Tools**

## Appendix J

# Monitoring Issues and Tools

Monitoring is conducted in three phases (described in Chapter 7, Section 7.2.2 *Program Phases*) and at three levels (described below). Level was a guiding principle of the conservation strategy, and goals and objectives were developed at the landscape, natural community, and species levels. This section provides an overview of what monitoring at each level involves, the issues or topics related to the three levels, and the general monitoring tools or approaches that will be used. Specific monitoring actions for each of the three levels are identified and discussed in Chapter 7, Section 7.3 *Monitoring and Management Actions*.

## J.1 Landscape Monitoring Issues and Tools

Landscape-level monitoring is directed at geographically large areas (e.g., the entire Reserve System or large portions of the Reserve System) that maintain essential ecological processes. Functioning landscapes encompass multiple ecosystems and natural communities and the movement of nutrients or materials between those units. Landscape-level monitoring addresses the following issues relevant to the Plan.

- The amount of land cover types in the Reserve System and their relationship to each other (e.g., succession or conversion from one community type to another, transitions zones between communities).
- Status and trends in the amount and quality of land cover types, natural communities, and other landscape features.
- The integrity and quality of landscape linkages and their potential role as dispersal and movement routes and corridors to preserve or maintain connectivity throughout the study area.
- The delineation of watersheds and maintenance of the general hydrologic function of those watersheds in and out of the Reserve System.
- The location, distribution, and range of invasive plants, nonnative wildlife species, and disease in the study area.
- The frequency, intensity, and geographic scope of disturbance events such as fires and floods.

The purpose of monitoring changes in the extent of land cover types within the planning area is to track long-term, landscape-level changes and, by inference,

changes to the habitats and natural communities contained therein. Long-term changes can indicate local, regional, or global problems such as unanticipated impacts of covered activities, influence of invasive species, and effects of climate change. Monitoring long-term changes will also track the contribution of the HCP/NCCP toward maintaining or improving the extent, distribution, and continuity of natural land cover types. Changes in land cover type will result from management actions (e.g., conversion of unvegetated streams to riparian woodland/forest; see Chapter 5). If landscape-level changes differ from the expected outcomes due to management actions, the Implementing Entity will attempt to identify reasons for the differences and address them through the adaptive management program as appropriate.

## J.1.1 Landscape Monitoring Issues

Following is a brief description of concepts and issues that are addressed under the topic of landscape-level monitoring. Broad issues relevant to landscape-level monitoring are discussed in this appendix. Specific monitoring actions are addressed by phase in Chapter 7, Section 7.3 *Monitoring and Management Actions*.

### Habitat Fragmentation

Since reduction of available habitat and fragmentation at a landscape level are among the principle causes of species decline, identifying and preserving key linkages is a primary objective of this Plan. The term *landscape linkage* is used in this Plan to refer to contiguous areas of habitat that connect larger areas of habitat and facilitate genetic exchange within a population or between subpopulations by allowing for movement within or between habitat patches. (For discussion on key landscape linkages and a description of acquisition targets in the study area, see Chapter 5, Section 5.3.1 *Land Acquisition and Restoration Actions*, **Table 5-6**, and **Figure 5-6**.)

In order to understand the level of stress that habitat fragmentation puts on populations of covered species it is important to understand how the existing linkages function and whether they are effective at supporting metapopulations in the Reserve System. There are two important components of monitoring landscape linkages (Bennet 2003). First, it is important to gain a basic understanding of the key linkages that occur within the study area and the representative species that utilize those linkages (status and trends monitoring). These species can serve as indicator species when determining which linkages will be protected and managed and whether they are functioning properly. It will not be possible to gain baseline information on every potential linkage, but linkages that contain landcover features representative of important types in the Reserve System (e.g., riparian corridor, grasslands, conifer woodland) will be studied. Second, it is important to monitor the effectiveness of linkages to determine whether they are achieving their goals (effects monitoring). Again, it may not be possible to monitor every linkage within the Reserve System, but

representative examples will be surveyed. In general, monitoring these linkages can take several forms.

- Regular monitoring of the occurrence and status of the plants and animals within linkages (either living there or passing through) to provide information on how the link is being used and the species for which it facilitates connectivity.
- Monitoring of individual animals within the linked system (e.g., by radiotelemetry) to obtain data on the extent, frequency, direction, and type of movement made through particular linkages.
- Monitoring the status of populations and communities in habitat connected by linkages to assess response to changes in connectivity.

Effectiveness monitoring will likely include all three of these methods at some point during the permit term. The effectiveness of linkages for wildlife species will be determined by monitoring indicator species, such as tiger salamander, bobcat, Tule elk, American badger, black-tailed deer, and mountain lion. Sampling methods will be determined upon implementation but generally will include track plates, motion-activated cameras, and transect surveys that could reveal scat or other visual evidence for terrestrial wildlife. The methods will be implemented both within linkages and in core habitat areas on either side of identified linkages.

These surveys will aid in determining whether linkages are functionally allowing passage between two points or whether enhancement of the area between two known habitat areas is necessary. Sometimes linkages will be monitored at natural pinch points, such as riparian corridors, or unnatural pinch points, such as culverts or bridges. In other cases, more rigorous monitoring could be used to determine how a given species uses the landscape. For example, radio-telemetry studies of Tule elk or American badger might be conducted. These species are grassland specialists but can range widely on the landscape, providing some insight into the overall “connectedness” of the Reserve System. There is already some general monitoring of wildlife movements occurring in the study area. These are track surveys and camera monitoring stations near underpass crossing points along U.S. 101. It is generally thought that U.S. 101 is a significant hindrance to any major wildlife movement east-west through the study area, but these recent observations are showing that movement of all sizes of mammals is occurring (T. Diamond pers. comm.) There are proposals to expand this work in scope and rigor to better understand how various species are moving through the study area and what the limiting factors are for larger carnivores (e.g., mountain lions) to persist.

## **Invasive Plants and Animals**

Invasive species control is a serious regional issue and must be evaluated at that level as well as at the site-specific level. For example, exotic plants that occur in the study area must be identified and prioritized regionally for eradication or control. To ensure Plan success, efforts to eradicate or control existing invasive

species and to prevent new invasions in the Reserve System will be coordinated with other land management agencies and private landowners in the region, as described in Chapter 5, Section 5.3.2 *Landscape Conservation and Management*.

The monitoring program will track the success of eradication and minimization efforts for invasive species through status and trends monitoring as well as through the development and execution of directed studies that evaluate the efficacy of different techniques. Depending on the resource issue and the level of the monitoring effort, this monitoring might occur at varying frequencies. For example, site-specific monitoring of nonnative plant species might be conducted annually, while a watershed-wide inventory might only occur every 5–10 years. The Implementing Entity and their consultants will take measures to reduce the spread of invasives during monitoring

## **Feral Pigs**

In some cases monitoring exotic species can be best accomplished by documenting the impact of those species on natural landscapes. It would be difficult to census the number of feral pigs within the Reserve System without an extensive effort. However, rooting disturbance can be monitored. Pig population will be controlled until rooting disturbance reaches an acceptable level. .

## **Bullfrogs and Nonnative Predatory Fish**

Following a baseline inventory of nonnative predators (e.g., fish and bullfrogs) in ponds and perennial wetlands within the Reserve System, a systematic eradication program will be implemented. Threats will be prioritized, and the progress of this program will be monitored on an annual basis by repeating the inventory on ponds that have been treated for nonnative animals and ponds that did not support nonnative animals during the initial inventory. This procedure will allow the Implementing Entity to evaluate the success of the eradication program, to detect the spread of these species to unaffected parts of the Reserve System, and to eradicate them as new invasions are identified. Ideally, sites that do not receive treatments (i.e., control sites) will be used to improve understanding of the effectiveness of eradication efforts. However, in the case of serious new infestations or highly invasive species, the management goal may be complete eradication; in such cases, control sites may not be feasible.

Similar inventory and survey efforts will occur in designated sections of riverine and riparian habitat. It is more difficult to eradicate nonnative bullfrogs and fish in riverine systems or along riparian corridors than in isolated aquatic habitats (e.g., ponds) unless the entire length of the system is treated. Monitoring nonnative animals in these habitats will focus on determining population levels. Population control efforts will reduce populations of nonnative animals to levels that facilitate the successful implementation of the conservation strategy described in Chapter 5 of this Plan and maintain those levels in designated reaches of high ecological value (e.g., critical habitat, modeled habitat, known

covered species occurrences). Monitoring the effectiveness of population control methods will entail surveys and inventory of nonnative animals but will also involve surveys of selected native species to determine the net benefit of these conservation actions. For example, population levels of native amphibians might be monitored along a reach of stream where bullfrog control has been implemented.

## Non-Native Mussels and Snails

Due to the recent discovery of the non-native zebra mussel in northern California reservoirs, a monitoring program has been enacted to determine the local source of the invasions and to identify solutions. The California Department of Fish and Game, the Department of Water Resources, and the Santa Clara Valley Water District have taken the lead on the monitoring effort. The Santa Clara Valley Water District has scheduled a visual inspection of the San Felipe Division intakes in San Luis Reservoir. This subsurface inspection will be conducted with the help of a remotely operated vehicle. The district is also working on performing subsurface inspections of other reservoirs in the study area. The goals of the monitoring are to determine if zebra mussels are present in any SCVWD reservoirs. Test plates will be installed at Calero and Anderson reservoirs and at the San Felipe Division intakes. The test plates are a Plexiglas substrate that is commonly used to detect colonies of zebra or quagga mussels. The plates will remain in the reservoirs for at least a month.

The SCVWD has formed a task force with the Alameda County Water District (ACWD) and the Zone 7 Water District in Livermore to coordinate monitoring efforts. The SCVWD has also set up an internal task force to manage the threats of both zebra and quagga mussels.

Similar efforts will need to be taken to monitor the spread of New Zealand mud snails.

## Disturbance

Within the context of this Plan, a disturbance is a temporary or intermittent change in environmental conditions that causes a pronounced change in an ecosystem. Ecological disturbances include natural events such as fire, drought, and flooding as well as nonnatural or anthropogenic events such as habitat fragmentation through development or the introduction and spread of nonnative species (Dale et al. 2001).

Monitoring will record the frequency, intensity and location of natural disturbance events, and these results will be compared to historic incidence of disturbance in an attempt to foster natural disturbance, as feasible. In general, flooding will be allowed within the Reserve System and in identified natural areas outside the Reserve System. (See the *Natural Flood Protection* section in Chapter 5.) A more detailed description of the fire-containment policy and in

instances where fires will be allowed to burn is found in Chapter 5 (*Minimum Impact Fire Suppression Techniques*).

## Disease

Disease, as defined by this Plan, is a condition leading to decreased or impaired function or increased rate of mortality in plants and wildlife; it can be caused by a variety of pathogens. Disease is a serious threat to plant and wildlife populations throughout California, including the study area, and can be detrimental to the health and function of entire ecosystems.

Disease must be carefully monitored in the Reserve System. Measures to reduce the spread of disease during monitoring activities will be taken by the Implementing Entity or its contractors. Monitoring includes identifying serious outbreaks, quantifying changes in infection rate or target diseases, and determining the impact on plant and wildlife populations, when applicable. Diseases must be identified and prioritized regionally for eradication or control when possible. Efforts to eradicate or control existing infected species and to prevent the spread of pathogens in the Reserve System will be coordinated with other land and resource management agencies in the study area and the region. In particular, monitoring diseases that affect covered and other native species will be coordinated with the Santa Clara County Division of Agriculture, the agency that monitors animals that serve as human disease vectors in the County. When feasible, large private landowners adjacent to the Reserve System will also be involved. Coordination could include sharing costs, staff, and equipment and conducting joint monitoring programs to address the regional problem of disease.

Sudden oak death (SOD), caused by the pathogen *Phytophthora ramorum*, is a serious threat to oak woodlands and mixed evergreen forests in northern California and an example of one of the diseases that will be monitored within the study area. Several species of trees in the study area have been identified as hosts to this pathogen: coast live oak, California black oak, California bay laurel, madrone, California buckeye, and big-leaf maple (Davidson et al. 2003). In addition, there are several instances of confirmed SOD near or at the border of the study area. SOD appears to be widespread along the northwestern portion of the Santa Clara County border, just outside the study area<sup>1</sup>. There is also a confirmed incidence of SOD at the border of the Almaden Quicksilver County Park. Trees near the Almaden occurrence will be monitored frequently.

Several consortiums and organizations have been formed to manage and monitor this critical issue. The California Oak Mortality Task Force—a coalition of research/educational institutions, public agencies, nonprofit organizations, and private interests including agencies such as the USDA Forest Service, the National Park Service, the California Department of Forestry, and the University of California—is focused on establishing appropriate monitoring regimes for the disease. The University of California's Center for the Assessment and Monitoring of Forest and Environmental Resources (CAMFER) is working with

<sup>1</sup> See recent maps at: <[http://nature.berkeley.edu/comtf/html/comtf\\_organization.html](http://nature.berkeley.edu/comtf/html/comtf_organization.html)>.

the California Oak Mortality Task Force and is implementing monitoring strategies at various levels. At a regional level, these organizations are combining aerial surveys with ground sampling<sup>2</sup>. At the landscape level, they are using remotely sensed data to determine the condition and pattern of trees with SOD, and at a local level, they have established research plots in various areas in Northern California that are examined every 2–3 months for various types of damage (Kelly and McPherson 2001). Monitoring efforts in the study area will be consistent with the methods used by these organizations.

## Hydrologic Function

Maintaining the hydrologic function of the study area is a primary objective of this Plan (**Objectives 1a.1, 1a.2, and 1b.1** in **Table 5-1a**). Aquatic ecosystems—including streams, rivers, ponds, and wetlands—are structured by hydrological processes operating at multiple levels.

Hydrologic function can be broadly defined as the flow of water through a landscape and the processes controlled or influenced by those flows. Hydrologic functions are driven by precipitation and include infiltration, runoff, groundwater recharge, and the quality and quantity of water within channel networks and other water bodies.

The Plan has committed to maintaining and, where feasible, improving hydrologic function within the study area, as described in detail in Chapter 5, *Conservation Strategy*. To that end, the Plan will incorporate Water District data (e.g., water level, water temperature, turbidity, stream flow, impervious surfaces, groundwater) and augment when necessary with limited additional sampling stations to be identified in the first year of implementation and functioning within two years of implementation. Water quality monitoring requirements associated with development (*Condition 3. Maintain Hydrologic Conditions and Protect Water Quality*) will also be reviewed annually by the implementing entity to ensure that the goals of the Water Quality Condition are being met and that the condition is effective.

## Impacts of Recreation

Recreation within the Reserve System will be monitored to determine if uses are having adverse effects on covered species that may be sensitive to human disturbance (e.g., San Joaquin kit fox, western pond turtle, covered plant species [**Table 4-1**]).

Monitoring will distinguish between different types of uses (e.g., hiking, horseback riding) that can have varying levels of impacts on covered species.

---

<sup>2</sup> They are also using the OakMapper website <<http://kellylab.berkeley.edu/SODmonitoring/OakMapper.htm>> to submit new incidents of infection.

Monitoring will also be designed to help inform if and when seasonal or other restrictions on recreational uses will be imposed in sensitive areas (e.g., in sensitive vegetation, near ponds that support covered amphibians and reptiles).

## J.1.2 Landscape Monitoring Tools

Because most effectiveness monitoring takes place at the natural community and species levels, monitoring at the landscape level focuses on detecting changes in natural process that cannot be detected on smaller scales, such as community or species. This type of monitoring will ensure that impacts, as specified by the Plan, on biological resources are not exceeded; that preservation/enhancement, restoration and creation requirements are being implemented and met; that threats are being targeted and reduced; and that any large-scale issues affecting resources regionally are identified early and addressed. Following is a description of some of the tools that will be used to monitor status and trends at the landscape level.

### Pre-Acquisition Assessments

Information on landscape features will be collected through pre-acquisition assessment and other field surveys that provide information on the extent and distribution of land cover types in the Reserve System. These data will be used to refine currently existing species habitat models. Additionally, this information will be combined with other landscape-level information being collected by others in the region to provide resource managers, including the Implementing Entity, with an understanding of how critical biological resources are generally trending under the influence of Plan implementation as well as under the influence of other human activities and other environmental factors (e.g., fire, drought, disease). Results of pre-acquisition assessment will be merged with the results of other fieldwork to determine baseline conditions and to evaluate future changes against that baseline.

### Remote Sensing

At the landscape level, the Implementing Entity will monitor, using aerial photos or satellite imagery, the extent and distribution of Plan land cover types within the study area every 5 years. Land cover mapping will be verified in the field at sites where air photo interpretation is difficult. Current species models (**Appendix D**) reflect the landscape-level data available at the time of the writing of this Plan (December 2006). Species models will be improved as new data become available.

Additionally, landscape-level information generated through pre-acquisition assessments and other surveys will be crosschecked against periodic updates to the land cover map from aerial photos or satellite imagery described above. The Implementing Entity will coordinate landscape-level monitoring with future

regional mapping efforts that may be conducted by others within the study area (e.g., The Nature Conservancy, CDFG).

## Mapping of Invasive Plants

The goals of the Invasive Plant Control Program described in Chapter 5 are to control the spread of noxious weeds (as defined by the California Department of Food and Agriculture) and invasive exotic plants listed by the California Invasive Plant Council (California Invasive Plant Council 2007 or latest list) into new areas and to control infestations of noxious and serious weeds, where practicable. Within the Reserve System, the Implementing Entity will map occurrences of noxious weeds and invasive exotic plants as they are identified (by planning and other surveys) and periodically monitor these occurrences. The Implementing Entity will also prioritize control and removal efforts. The frequency of monitoring will depend on the threat that species pose to native biological diversity. For example, invasive plants that occur within the reserves and have the ability to spread rapidly will be monitored more frequently (e.g., several times per year). Species that spread slowly will be monitored less frequently (e.g., every 1–5 years). Additionally, Implementing Entity field staff will look for occurrences of new invasive plants that require immediate eradication or control actions within the Reserve System. Field workers will follow proper decontamination procedures prior to entering and exiting an area they are working in to stop spread of weeds, seeds, or disease between areas.

## J.2 Natural Community Monitoring Issues and Tools

The Implementing Entity will conduct monitoring to assess ecosystem and natural community function. Natural community–level monitoring focuses on local resources and threats to communities and habitats as well as the response of each natural community to management actions (especially restoration and enhancement). Natural community monitoring includes, but is not limited to, the following issues relevant to the Plan.

- The extent and quality of natural communities and the relationships between their constituent elements.
- Natural community function including the ability of these communities to withstand natural and anthropogenic stressors and threats.
- The effectiveness of the conservation measures in enhancing, creating, or restoring natural communities and their associated features (e.g., ponds, riparian woodland) and the ability of these areas to provide their intended ecological functions and values.
- The response of keystone species (i.e., species such as California ground squirrels that affect the community in greater proportion than their relative abundance) to management actions.

- Community dynamics such as grassland burrow systems.

## J.2.1 Natural Community Monitoring Issues

Following is a brief description of broad concepts and issues that are germane to natural-community-level monitoring. Specific monitoring actions are addressed by phase for each natural community in Section 7.3.2 *Natural Community–Level Actions*.

### Removal or Disturbance of Keystone Species

A keystone species is one that affects its environment disproportionately more than its abundance or biomass would suggest (Paine 1969; Power et al. 1996). An important component of natural community monitoring is the identification of any keystone species that strongly influence relationships within that community. An example of a keystone species in the study area is California ground squirrel. This species' burrows provide nesting habitat for western burrowing owl and upland refugia for California red-legged frog and California tiger salamander. In addition, California ground squirrel is an important prey item for many grassland-associated species, including the San Joaquin kit fox, which is a covered species. Accordingly, California ground squirrel is recognized as a keystone species for grasslands and will be monitored in grasslands as a measure of the effectiveness of that natural community to support the covered species that depend on ground squirrels. The effect of coyotes on red fox, as well as the effect of mountain lions on deer herbivory and raccoons on red-legged frogs and pond turtles, could also be considered keystone species. Other keystone species will be identified as the conceptual models are developed.

### Predation by Nonnative Species

Predation plays a pivotal role within many natural communities, and the presence or absence of predators can strongly influence community dynamics. While predation is often defined to include herbivory, for the purposes of this Plan, grazing is described separately below. Predation has an ecological role at the community level. Primarily, predation regulates prey populations, which in turn affects community structure. In short, the absence of natural predators can cause abnormal levels of prey populations, thereby affecting the structure and composition of the plant community. An intermediate intensity of predation is associated with high prey diversity by promoting the competitive exclusion of some prey species (Begon et al. 1996). The presence of invasive or nonnative predators can severely disrupt native prey populations that have not evolved defense mechanisms in response to those predators.

Examples of predation and its potential effect on natural communities include feral cats that affect wildlife relationships in riparian and grassland natural communities by altering the nest success of native songbirds and reducing

populations of native rodents, which in turn suppresses the prey base for many native raptors and carnivores (Begon et al. 1996). In grasslands, nonnative red foxes outcompete native foxes (e.g., San Joaquin kit fox) by reducing the prey base of native rodents (Hall 1983; Berry et al. 1987; Ralls and White 1995), which also affects native raptors. Within the study area, a potentially significant cause of red-legged frog decline is predation by nonnative bullfrogs (Lawler et al. 1999).

Nonnative species (e.g., red fox, bullfrogs and some nonnative fish) will be controlled if data indicate that the impacts from predation and/or competition on covered species or natural communities preclude the successful implementation of the conservation strategy described in Chapter 5 of this Plan. The patterns of predation between species will be examined for each natural community.

## Altered Fire Frequency

Fire is an important form of disturbance with particular relevance to chaparral, grassland, and oak woodland communities (see description of fire and its role in natural communities in Chapter 3). It is unclear how fire patterns in the study area have changed over time, and additional study is required to attempt mimicry of historic fire regimes (if feasible). In southern California the frequency of fire in shrublands is thought to be as frequent or more frequent in the twentieth century than it was in the nineteenth century (prior to fire suppression activities), partly because fire suppression activities have been ineffective at reducing fire frequency in shrublands (Keeley et al. 1999; Keeley and Fotheringham 2001). The frequency of severe weather conditions (i.e., low humidity, high winds, and drought) and the number of people with access to stands (providing an ignition source) appear to play much more important roles than do vegetation conditions in determining fire risk. Fire management is discussed in detail in Chapter 5, *Conservation Strategy*, and fire history in the study area is depicted in **Figure 10-1**.

Prescribed burning is an important tool to restore the historic patterns of fire in natural communities in the study area. It will be necessary to monitor the impacts of unplanned and prescription burns on native and nonnative vegetation within the Reserve System. Vegetation sampling to document a baseline condition for comparison will precede prescribed burning. The result of this monitoring will inform the effectiveness of burning as a tool to regenerate grassland, chaparral, and oak woodland natural communities. The purpose of burning is to reduce the biomass of nonnative vegetation while encouraging regeneration of fire-adapted native species.

## Livestock Grazing

Much of the flora of the study area evolved under the influence of prehistoric herbivores—large herds of deer (primarily a browser on shrubs and trees), elk, antelope, and other grazing animals. Grassland and in particular serpentine

grassland communities can be greatly influenced by the intensity, timing, and type of grazing (for further description see Chapter 3). At present, livestock grazing utilizing cattle, sheep, or goats is an essential vegetation management tool to maintain and improve habitat conditions for some native plants and animals and to reduce fuel loads for wildfires (see Chapter 3).

Grazing in certain native grassland communities, however, may be inappropriate or may need to be reduced to maintain or enhance these communities. Accordingly, the response of native plant populations to grazing regimes in grasslands, shrublands, or other rangelands will be monitored. Further, the response of nonnative vegetation will also be monitored to determine which grazing rotation or which combination of rotations is most effective at reducing nonnative vegetation to an acceptable level. These surveys can be supplemented with other evaluation of other natural community metrics such as percent of native shrub cover and overall species richness. Grassland songbirds can be monitored during the breeding season to measure species diversity and richness relative to each grazing regime. They can also be monitored as an effective surrogate to measuring overall grassland structure (e.g., percentage of ground cover, height of vegetation). In some grassland communities the presence of particular songbird species could be used as a surrogate for grassland health. These techniques will be explored during the targeted studies phase of implementation. Compliance monitoring will ensure that the livestock are grazing at the HCP-required levels.

## Altered Stream Flow

The diversity and abundance of aquatic organisms are shaped by six primary factors: flow regime (the pattern of water quantity over time); water quality; physical habitat (e.g., the morphology of a stream channel); food-web productivity; interactions with other species; and the connectivity between habitats, both longitudinal (upstream–downstream) and lateral (channel–floodplain). The flow regime has been called the “master variable” because it can strongly influence all the other factors (Poff et al. 1997). For example, the physical structure of a stream channel is shaped during floods as high-energy flows erode the channel and floodplain in some locations and simultaneously deposit sediment in other locations.

The flow regime is a function of watershed-level patterns of precipitation and runoff, which are strongly influenced by vegetation cover, underlying geology, and land use. For example, impervious surfaces can lead to a “flashier” runoff regime—higher peak flows and lower base flows—by reducing the amount of precipitation that infiltrates the ground. Thus, more precipitation rapidly reaches the channel network and less infiltrates into shallow groundwater to support baseflows during periods of low or no precipitation. Changes in flow regime strongly affect the quality of habitat for covered species within the aquatic and riparian land cover types and influence the structure and composition of the riverine and riparian natural communities. Because of their importance, the hydrological variables listed below will be monitored within the study area.

- **Baseflows.** Monitoring of baseflows over the entire year will ensure that sufficient water exists during critical stages of the lifecycle of target organisms (e.g., rearing of juveniles, upstream and downstream passage). SCVWD monitors stream flow releases at its reservoirs and at other stream flow gauges
- **Flooding and droughts.** In target areas, managed flooding or drybacks or processes that mimic flooding and drought will be implemented to create scour or tree mortality and to promote a variety of successional stages of riparian forest and scrub.
- **Temperature.** This important ecological variable is strongly influenced by the flow regime and impacted by changes to runoff associated with land clearing and development. Temperature measurements are already taken by SCVWD and will be supplemented by the Implementing Entity, as described earlier under *Hydrologic Function*.

## J.2.2 Natural Community Monitoring Tools

While monitoring occurs at three spatial levels, the natural communities provide the organizational framework for monitoring—species are associated with and occur within natural communities. Landscapes are made up of collections of natural communities. In this way, understanding natural communities and evaluating the effects of management on natural communities is one of the most important tasks of the monitoring program. The following sections describe approaches that will be used to monitor natural communities.

### Conceptual Ecological Models

Conceptual ecological models (conceptual models) describe the current understanding of a functioning ecosystem. They provide a framework for learning about a system and help formulate hypotheses about cause-and-effect relationships. Conceptual models are useful for management because they can represent and document uncertainty (Williams et al. 2007). They also help summarize information about a system, identify which factors may be influenced by management, and help identify critical uncertainties for targeted studies (Atkinson et al. 2004).

Conceptual models can inform the monitoring program in several important ways:

- by providing a basis from which to test assumptions about the relative importance of certain processes,
- by helping to identify threats or stressors that require monitoring,
- by identifying species or other attributes that function as indicators,
- and by serving as a repository of the changing understanding of the system as more data become available.

Conceptual models can also be used to communicate understanding of the system to other scientists and the public and to facilitate review by outside experts. Numerous studies have confirmed that the use of conceptual models greatly assists the development of monitoring and adaptive management programs (Elzinga et al. 2001).

Models can be either narrative or diagrammatic. In most cases, diagrams show the hypothesized relationships that characterize the ecosystem and are supplemented by written materials. Several types of models can be used, including stress-response models and habitat models (e.g., those developed for species accounts **Appendix D**). In one stress-response model (**Figure 7-6**), stressors and threats are aligned along the left tier of the model, the central tier displays habitat responses, and the right tier shows hypothesized responses of covered species. An example of a more complex stress-response model is shown in **Figure 7-7**.

A conceptual ecological model was developed for the Grassland habitat type (**Figure 7-8**). It provides guidance for the development of additional models and shows how that modeling process can help to elucidate assumptions and directly inform monitoring. In the inventory phase, the Implementing Entity will develop conceptual models for each natural community type. A critical task in the development of these models is the identification of uncertainties and threats or stressors. The identification of uncertainties provides a springboard for additional targeted studies. The models will also incorporate the anticipated effect of management actions on natural communities.

## Natural Community Inventory Protocols

Once a parcel for the Reserve System has been acquired, a thorough vegetation and wildlife community inventory will be conducted. The inventory will build on the results of the pre-acquisition assessment. This inventory will draw as much as possible from accepted protocols for typing vegetation communities and wildlife habitats. These typing protocols include the California Native Plant Society “Vegetation Rapid Assessment Protocol” (California Native Plant Society 2002) and “Releve Protocol” (California Native Plant Society 2003) for plants. Another option is DFG’s Keeler-Wolf “protocols.” Protocols are updated frequently and the most recent or most appropriate protocols at the time of assessment will be used. Vegetation associations and alliances will be classified and mapped in more detail than the regional land cover classification used in this Plan to provide more accurate mapping and finer units to monitor over time. Streams will be mapped and included as one of the land-cover types addressed in the inventory protocols.

Similarly, acquired parcels will be surveyed for natural communities (including covered species habitats), invasive species, and other potential disturbances. Survey protocols will be developed by the Implementing Entity during the initial phase of implementation and additional details provided in the system-wide monitoring plan. These protocols will evolve through time. Where up-to-date protocols exist for a particular species, those will be used. Such protocols will include protocols in use by any of the wildlife agencies or those developed by

scientific processes (as in the protocols developed for burrowing owls for the Burrowing Owl Consortium). Other specific protocols that may be used for wildlife include live trapping, vocalizations/recordings, mist netting, observation scans, search transects or plots, infrared camera stations, and identification and mapping of tracks and scat.

Along with the existing species models, the California Wildlife Habitat Relationships (CWHR) classification is recommended to understand the relationship between natural communities, their habitat, and wildlife species (Mayer and Laudenslayer 1988). Information from CWHR or other wildlife-habitat systems, the results of protocol-level surveys, and any other relevant, new information will be incorporated into species and community models throughout the lifetime of the Plan. When feasible, the Implementing Entity will seek to develop protocols that use a multi-species or habitat-based approach.

## Monitoring Community Function

Conserving, restoring, and managing ecosystem function is a requirement of the NCCP Act<sup>3</sup>. Often, biotic or abiotic indicators are used to assess function. In this Plan conceptual models will be used to identify attributes selected for monitoring. For example, songbirds may be monitored across terrestrial habitat types as a guide to measuring overall natural community structure and function. Bay checkerspot butterfly may provide important information regarding the health of remnant native grasslands and serpentine plant communities (Launer and Murphy 1994). This information will be used in conjunction with an understanding of drought situations and a balance with water-supply needs. Measuring vegetation, benthic invertebrates, or arthropod species diversity may also be indicators of community function. It is important to recognize that covered species monitoring is not the metric by which communities are evaluated under the Plan and that the conceptual models will guide development of monitoring for community function.

## Evaluating Creation, Enhancement, and Restoration

One of the main components of natural community monitoring will be the assessment of natural community enhancement, restoration, and creation actions. Monitoring of enhanced, created, or restored habitat will focus on the community or habitat response and, where applicable, species response. Because natural communities are likely to occur in different stable states, determining the desired restoration goals is a complex but necessary first step (Hobbs and Norton 1996). The targeted studies phase will establish a range of measures or success criteria to evaluate restoration efforts for each natural community. This monitoring will ensure that the restored natural communities are functioning as habitat for particular covered species or suites of species associated with the subject communities. **Table 7-1** lists examples of standards and objectives that may be

<sup>3</sup> California Fish and Game Code Section 2820 (a)(4)(A).

the basis for assessing success of natural community enhancement, creation, and restoration conservation actions.

Key steps to evaluate restoration and creation projects (Hobbs and Norton 1996) are listed below.

1. Identify processes leading to decline (relevant to restoration projects).
2. Develop methods to ameliorate degradation or decline (relevant to restoration projects).
3. Determine realistic goals for functional ecosystems that still result in the creation of an ecosystem with similar ecological values to local equivalents.
4. Develop relevant, easily observable success criteria.
5. Develop practical techniques for implementing these goals and ensure that they are commensurate with the problem.
6. Document and communicate these techniques.
7. Adaptively manage the system.

The Plan has accounted for the financial costs of the monitoring program and the Implementing Entity will maximize efficiencies to determine where conservation dollars are best spent. This Plan provides example success criteria for the restoration/enhancement of each natural community type (**Table 7-1**). These recommendations are preliminary and are intended to guide future efforts and provide a tangible idea of the nature of the desired criteria. More permanent criteria will be established during the first five years of Plan implementation. It is beyond the scope of this Chapter 7, *Monitoring*, and this appendix to establish the final criteria for successful management and restoration. Moreover, other conservation planning efforts that have provided too much detail too early in the process have resulted in criteria that were ill-considered and inadequate and that needed to be amended during plan implementation (B. Johnson pers. comm.). The approach used in developing this Plan strives to provide the necessary guidance for developing rigorous and defensible criteria while providing flexibility for Plan implementation and the additional work, including pilot projects that will be conducted during the early phases of the Plan.

## J.3 Species Monitoring Issues and Tools

The Implementing Entity will conduct monitoring to assess the status of covered species and to determine the extent to which the biological goals and objectives for species are being met. Species monitoring will address the following issues relevant to the Plan.

- The response of covered species to Plan conservation actions and adaptive management.
- Status and trends of covered species and other relevant species on reserve lands and in streams.

- Trends in abundance for selected indicator species over the term of the Plan.
- The response of plant populations to impacts resulting from covered activities (Condition 22).

### **J.3.1 Species-Specific Monitoring Tools**

Species monitoring will provide data for use by the Implementing Entity as well as the Wildlife Agencies, universities, and wildlife conservation organizations to assess the overall status of species populations, to identify species conservation needs, and to direct future conservation efforts. This information may also be used to redirect Plan conservation efforts in future years (e.g., reserve management prescriptions) to improve conditions on reserve lands for declining species. (Any redirection of Plan funds in response to monitoring must be carried out in accordance with the terms and conditions of the Implementing Agreement and permits, including the No Surprises assurances.)

#### **Surrogate Species**

It may be difficult to detect individuals of certain species due to small body size, rarity, or behavior. In such cases, other species can be used as surrogates for covered species that are difficult to monitor. The Implementing Entity will document the rationale for using surrogates. A more general discussion on indicator species is provided in Section 7.2.4 *Guidelines for Monitoring*.

#### **Focal Covered Species**

The status of all covered species will be monitored during the 50-year permit term. To facilitate the monitoring of covered species, a multi-species approach will be used, to the extent possible, for long-term monitoring. Focal species are defined in the literature in different ways. They can be used as indicators in landscape or community-level monitoring (Lambeck 1997) or (as in this Plan) as indicator species that are used in multi-species monitoring. In either case focal species should be sensitive to threats providing information on the suite of species with which they are associated. Focal covered species within species groups will be monitored routinely to provide the data most likely to influence the conservation strategy and to manage costs effectively. In some cases, focal covered species may be used when information on some species is highly correlated with other species, and intensively monitoring all species provides little additional information.

Species will be grouped for ease in prioritizing and standardizing survey requirements for individual species. If appropriate, sampling stations may be used to collect information on multiple species.

## Habitat Indicators for Species

Selecting the best attributes by which to measure the population status of covered species increases the effectiveness of monitoring. Monitoring adult abundance and distribution of covered species is often the most appropriate, direct measure of status. However, in many cases monitoring protocols for certain species yield variable and imprecise results or require a prohibitively expensive sampling effort. In these cases key habitat variables may be used—in conjunction with other information—to evaluate species status. This method requires targeted studies to verify the relationship between the habitat attribute and the species status and will be periodically retested to ensure that the relationship between the indirect indicator and the condition of the species does not change. See *Indicators* in Section 7.2.4 *Guidelines for Monitoring* for additional information on selection of biotic and abiotic variables. An effective monitoring program balances efficiency and cost effectiveness with the reliability of the information obtained.

## Species Models

### Species-Habitat Models

Parameters for the existing species-habitat models (**Appendix D**) will be refined and revised throughout Plan implementation as more information becomes available. At a minimum, models will incorporate any new land cover information that becomes available as part of the periodic update of GIS layer with aerial photographs or satellite imagery (every five years). Models will also be updated when new scientific or on-the-ground information that influences model outcome becomes available. If possible, species-habitat models will be developed for those species that did not have models developed for this Plan.

These species-habitat models document the best current understanding of the biological and physical parameters that influence each species and, in this way, are species-specific conceptual models. Species-habitat models were developed for most covered species using GIS to hypothesize a relationship between land cover type and other habitat associations and the distribution of covered species. These models (**Appendix D**) have served as the basis for estimating impacts and prioritizing land acquisition. Information from the pre-acquisition assessment and post-acquisition inventories will further refine these models such that they can be used to help predict distribution and occupancy and to assess population trends. Species occurrence information on Reserve Lands will also be used to update species models.

### Species Conceptual Models

As described above, conceptual models are an important component of the Monitoring and Adaptive Management Program. In addition to ecological models, conceptual models will be developed for covered species as well. The

priority of model development for each species group is defined in Section 7.3.3 *Species-Level Actions*. An example species conceptual model was developed for the California tiger salamander (**Figure 7-9**). It provides guidance for the development of additional models and shows how the modeling process can help to elucidate assumptions and directly inform monitoring. In the inventory phase, the Implementing Entity will develop conceptual models for Group 1 species. A critical task in the development of these models is the identification of uncertainties and threats or stressors. The identification of uncertainties provides a springboard for additional targeted studies. The models will also incorporate the anticipated effect of management actions on covered species.

## **California Tiger Salamander Hybridization**

# Appendix K

## California Tiger Salamander Hybridization

### Introduction

Introgression, or the incorporation of genes from one species into the gene pool of another as a result of hybridization, occurs through natural processes such as species range expansion and natural selection. It is also sometimes the result of human-related disturbance. Barred tiger salamanders (*Ambystoma tigrinum mavortium*) were introduced to California over 50 years ago and have hybridized with native California tiger salamanders (*Ambystoma californiense*). The number and range of these non-native salamanders and their hybrid progeny have expanded since introduction. This appendix summarizes the most applicable scientific literature to date and outlines the strategy to manage California tiger salamanders in the Santa Clara Valley Habitat Plan (Habitat Plan) through the adaptive management process.

To manage California tiger salamanders populations in a manner that achieves the biological goals and objectives set in the Habitat Plan, we first need to identify the potential negative impacts of hybridization and introgression. Further, we must better understand any ecological impacts that non-native and hybrid salamanders have on aquatic communities in the study area. Rather than assuming that all hybrids should be controlled, we need to determine whether a population with introduced alleles (potential variants of a gene) functions ecologically in a similar manner as the native population (Fitzpatrick et al. 2010).

The Habitat Plan will treat individuals morphologically resembling the threatened Central Distinct Population Segment of the California tiger salamander as if they were the listed entity. Take prohibitions will still apply to all individuals morphologically resembling the listed taxon. The primary reason for the initial management strategy described below is to provide the Habitat Plan with flexibility to deal with the diverse situations resulting from more than 50 years of interbreeding between *Ambystoma californiense* and *Ambystoma tigrinum mavortium* within portions of the California tiger salamander's range (Fitzpatrick and Shaffer 2004). In this case, elimination of all or even most introgressed impure populations is not likely feasible due the extent of the invasion, extent of unsurveyed habitat, longevity of the species, and biphasic life history of the species, which is predominately spent in underground burrows (Fitzpatrick and Shaffer 2007a). The hybrid management plan does not preclude the Wildlife Agencies' ability to approve, on a case by case basis, the Implementing Entity's eradication of introgressed progeny if the presence of

these individuals is determined to interfere with conservation efforts for the listed entity or other covered species.

## Release and Expansion History

Barred tiger salamanders were introduced to specific locations in California starting in the early to mid-20th century by bait dealers and fishermen, who used the larvae as live bait (Fitzpatrick and Shaffer 2007a).<sup>1</sup> This subspecies of barred salamander is native to parts of Texas, eastern New Mexico, Oklahoma, Kansas, Nebraska, eastern Wyoming, and Colorado. It has been found in isolated locations throughout much of California. The barred salamander is much larger than the California tiger salamander (it is the second largest salamander in the United States) and exhibits different behavior and life-history traits than the California tiger salamander. Native California tiger salamanders and introduced barred tiger salamanders have been hybridizing for 50–60 years (Fitzpatrick and Shaffer 2007b). Importantly, barred tiger salamander adults retain juvenile traits such as gills when they breed in aquatic habitats. These individuals, called “paedomorphs,” provide the opportunity to readily distinguish barred salamanders and hybrids from native California tiger salamanders in breeding ponds and wetlands.

Introduced and hybrid tiger salamanders in the south and east San Francisco Bay have likely dispersed there from known introduction sites in the Salinas Valley (Fitzpatrick and Shaffer 2007a). In the Salinas Valley, many sampled tiger salamanders had high frequency of introduced alleles or high hybrid index (Fitzpatrick and Shaffer 2007a). In California, an abrupt transition from high (but variable) to very low introduced allele frequencies occurs at a distance of greater than 7.5 miles (12 kilometers [km]) from release sites (Fitzpatrick and Shaffer 2007a). The Santa Clara County line is approximately 27 miles from the Salinas Valley release sites. More research is required to explain the abrupt change in allele distribution from high frequencies to very low frequencies of introduced alleles at sites greater than 12 km from release sites. One possible explanation for this observation may be the result of a strong selection for certain hybrid characteristics in local populations (e.g., hybrid survival is higher in permanent ponds) (Fitzpatrick and Shaffer 2007a). Another potential explanation is that the spread of the invasion is limited by salamander dispersal capabilities and that the “wave” of hybridization has only reached 12 km to date but continues to spread (Shaffer pers. comm. 2010).

## Santa Clara County Populations

California tiger salamander potential upland and breeding habitat is distributed throughout undeveloped areas of Santa Clara County, due to the presence of stock ponds and other aquatic habitat. Known occurrences are scattered

<sup>1</sup> The use of any salamander as bait in California and the transport or possession of any salamander in the genus *Ambystoma* is now illegal without a special DFG permit (California Department of Fish and Game 2009).

throughout Santa Clara County, on both sides of the valley, with large clusters of occurrences in Henry W. Coe State Park and Joseph D. Grant County Park (California Natural Diversity Database 2006).

Some level of hybridization is most likely present in a large number of ponds throughout Santa Clara County and may be high in some ponds in the southern portion of the county (e.g., Bluestone Lake, North Fork Pacheco Creek). Of the Santa Clara County populations genotyped, all had some low-level of hybridization (J. Johnson pers. comm. 2009), and one, Bluestone Lake, in southern Santa Clara County, had an average introduced allele frequency of 60% (Fitzpatrick et al. 2009). Three nonnative “superinvasive” alleles have been found in California tiger salamander populations as far north as the Contra Costa/Alameda County line (Fitzpatrick et al. 2009). These three genes represent only about 5% of the genes examined to date (Fitzpatrick et al. 2010). In addition to the Salinas Valley release site, barred salamanders were introduced in Santa Clara County in a perennial pond located east of North Fork Pacheco Creek in the early 1980s and in 1984 to a nearby pond that periodically dried (J. Smith pers. comm. 2010a). As a result, nonnative barred salamanders have been identified during surveys at the North Fork Pacheco Creek (above Pacheco Reservoir) (J. Smith pers. comm. 2010a). The North Fork Pacheco Creek release site is in close proximity of known California tiger salamander locations, such as those found in the southwest corner of Henry Coe Park and throughout the eastern portion of the Plan Area (Belli 2007; J. Smith pers. comm. 2010a, 2010b).

## Factors Affecting Hybridization

Hybridization between California tiger salamander and barred salamander is influenced by both environmental and biological factors. Initially, studies indicated that the survival rates of California tiger salamanders with low levels of introduced alleles may increase relative to native California tiger salamanders, due to a phenomenon called “hybrid vigor” in which cross-breeding produces higher survival rates (Fitzpatrick and Shaffer 2007b). The term “hybrid vigor,” or “heterosis” is a phenomenon where hybrid offspring have higher fitness than either of the pure parentals. For example, hybrid tiger salamanders have higher early larval survival rates (first weeks after hatching) than individuals with mostly native or mostly introduced alleles (Fitzpatrick and Shaffer 2007b).

More recent studies suggest however, that pure native California tiger salamanders are less fit than both hybrids and pure barred tiger salamanders. In a study conducted by Ryan et al., introduced barred tiger salamanders and hybrids appeared to reduce the survival, growth, and development rate of native California tiger salamanders (2009). Most contemporary hybrids in the study were larger than the native California tiger salamanders. Hybrids reduced the survival and growth rate of native California tiger salamanders through cannibalism and competition (Ryan et al. 2009).

Studies have detected a pattern of high introduced allele frequencies in perennial ponds and relatively even native and introduced allele frequencies in seasonal ponds within the introduction zone in the Salinas Valley (Fitzpatrick and Shaffer 2007a). This pattern may be due to overall selection for nonnative alleles leading to high hybrid larval survival in all ponds, particularly for barred tiger salamander characteristics in perennial ponds. Native California tiger salamanders must metamorphose into terrestrial adult salamanders (*metamorphs*) to reproduce, but barred tiger salamanders in perennial ponds often breed prior to metamorphosis, as sexually mature aquatic larval forms (*paedomorphs*) (Fitzpatrick and Shaffer 2004). Paedomorphs often reach sexual maturity earlier than metamorphs, produce larger clutches, and may breed earlier in a given season, leading to higher reproductive success in perennial ponds (Fitzpatrick and Shaffer 2007b). Paedomorphs grow larger than metamorphs, and females produce more eggs (Rose and Armentrout 1976 cited in Fitzpatrick and Shaffer 2004; Petranks 1998 cited in Fitzpatrick and Shaffer 2004). In addition, introduced barred tiger salamanders may be able to take better advantage of perennial ponds by breeding earlier in the fall, thereby giving their larvae a competitive head start over later breeding native California tiger salamanders (Fitzpatrick and Shaffer 2004). Ultimately these factors allow paedomorphs to outcompete metamorphs for the limited resources of a pond ecosystem.

## Ecological Effects of Hybridization

The presence of hybrid tiger salamanders may negatively impact native California tiger salamander population levels. As indicated above, Ryan et al. (2009) observed reduced survival and reduced growth and development rates in native California tiger salamander larvae that co-occurred with non-native salamanders and their back crossed progeny. Native tiger salamanders with slower growth rates because of hybrid salamander competition may have decreased survival in dry years (when ponds are more likely to dry before salamanders reach minimum size to metamorphose) and higher larval predation risk (Werner 1986). Native tiger salamanders with smaller sizes at metamorphosis may have lower adult fitness due to higher desiccation and predation risk (Ryan et al. 2009).

Hybrid tiger salamanders with high levels of introduced alleles have higher rates of predation on other native amphibians compared to native California tiger salamanders (Ryan et al. 2009). It is not known whether these high predation levels also occur in populations with only a few introduced alleles (Fitzpatrick et al. 2010). It has been demonstrated that the presence of hybrid tiger salamanders reduces the survival of other pond species. In one study, introduced barred tiger salamanders and hybrids reduced survival, growth and developmental rates of native California tiger salamander, California newt (*Taricha torosa*), and Pacific chorus frog (*Pseudacris regilla*) larvae (Ryan et al. 2009). California red-legged frog (*Rana draytonii draytonii*) and Santa Cruz long-toed salamander (*Ambystoma macrodactylum croceum*) larvae that reach a large enough size to avoid predation by native California tiger salamanders may not reach a large enough size to avoid predation by large hybrids (Ryan et al. 2009).

Only a small portion of the species' genome has been studied to date. As previously discussed, some studies suggest that hybrid tiger salamanders with low levels of introduced alleles have increased fitness and have the same general ecological traits as native tiger salamanders, although more research is required to be sure that they do not have other negative characteristics (e.g., paedomorphism) (Fitzpatrick and Shaffer 2007b; Fitzpatrick et al. 2010). Determining which non-native alleles are responsible for paedomorphism, overall size, and growth rate needs to be better understood. These physical characteristics appear to have the most significant ecological effect on the California tiger salamander (Shaffer pers. comm. 2010).

## Management of California Tiger Salamander Hybrids

### Initial Management Strategy

The Implementing Entity will adaptively manage California tiger salamanders and hybrids in close coordination with the Wildlife Agencies. Integration of the best available scientific data will be crucial in the adaptive management process as this initial management strategy is based largely upon studies targeting a small fraction of the species' genome and many more superinvasive alleles of unknown effect may have also introgressed into native populations (J. Johnson pers. comm. 2010b). Management will be updated as future studies provide us with better understanding of the functional aspects of the markers initially used to assess admixture proportions.

Rather than focusing management on genetic thresholds based on studies conducted on a relatively small portion of the species' genome, the initial management strategy will focus on restoring and maintaining wetland and pond conditions within the Reserve System that favor California tiger salamanders. Studies suggest that habitat characteristics of native species should be exploited in management strategies to limit hybridization (Riley et al. 2003). Perennial ponds studied in the hybrid zone often contained paedomorphic tiger salamanders, relative to more seasonal aquatic sites like vernal pools (Fitzpatrick and Shaffer 2004). Therefore, initial restoration actions will target sites where paedomorphs have been observed because presence of paedomorphs would indicate presence of non-native alleles in the tiger salamander population. Since different individual tiger salamanders are expected to return to breeding ponds every year, these targeted perennial ponds will be drained on an annual basis. Adaptive management will be used to determine the number of targeted ponds, evaluate effects on grazing, and the use of other available pond restoration techniques. As described in Chapter 5, ponds created for the Reserve System will be designed to rely on passive management (e.g., dry on their own periodically), minimizing the need for artificial draining and management (e.g., stock pond dams fitted with drainage structures). Annual draining of ponds may adversely affect other species covered under this Plan, such as the California red-legged frog or western pond turtle. As such, pond draining will be timed to

minimize effects on other covered species. Initially, a conservative approach may be taken to minimize adverse effects to metamorphosing California red-legged frogs (i.e., ponds should not be drained until late September). More studies would be needed to determine the amount of time paedomorphs require to fully metamorphose in order to disperse from breeding habitat to determine the efficacy of draining ponds and the timing of pond drainage.

Since the final Reserve System will be extensive and include up to 80 acres of wetlands and 104 acres of ponds (**Table 5-13**), the Implementing Entity will prioritize management sites for the purposes of California tiger salamanders unless doing so would preclude the Implementing Entity's ability to fulfill the conservation strategy for other aquatic covered species. Prioritization of management sites will take into consideration factors such as presence of paedomorphs, presence of other covered species, presence of non-native predators/competitors (i.e., fish and bullfrogs), condition of adjacent aquatic sites, and other factors.

Specific management strategies for hybrid salamanders will be incorporated in the applicable reserve unit management plans described in Chapter 5. The California tiger salamander management component of these plans will be updated as necessary to adapt to changing conditions in the reserves and to respond to monitoring or other new data. The Implementing Entity will review and, where biologically appropriate, systematically revise reserve unit management plans at least every 5 years. However, given the dynamic nature of the hybrid salamander situation, this component of the reserve unit management plan may need to be updated more frequently.

Future data may indicate that management of breeding habitat may not be adequate to fulfill the conservation strategy for the California tiger salamander. If that is the case, the Implementing Entity and Wildlife Agencies will evaluate the current management strategy and make appropriate modifications. Modifications could include active eradication of individuals based on scientifically-based genetic thresholds. Since there is a potential that the Plan may need to actively manage individuals later in the permit term, the Plan budget accounts for costs associated with genetic testing of tiger salamanders within the Reserve System, which may be necessary to substantiate future thresholds for management (see *Monitoring* below).

## Potential Management Strategy Modifications

Rather than establishing a threshold number of introduced alleles, above which an individual is considered a hybrid, it is necessary to determine whether the population with introduced alleles functions ecologically in a similar manner as the native population (Fitzpatrick et al. 2010). California tiger salamanders in Santa Clara County have been documented carrying three fixed alleles (called "superinvasive alleles") from the introduced barred salamander. If those salamanders still function in a way similar to native California tiger salamanders it may be appropriate to treat them as the native species (Fitzpatrick et al. 2010).

Currently, little is known regarding the effects of these three alleles. Researchers are proposing a set of experiments to examine these effects.

In the Salinas Valley to San Francisco Bay hybrid zone, approximately 5% (3 alleles) of genotyped native alleles have been almost completely replaced by the superinvasive alleles (Fitzpatrick et al. 2009). Since we do not yet know the morphological and ecological consequences of the fixation of introduced alleles, Fitzpatrick et al. (2009) recommend treating these the same as native California tiger salamanders.

Eradication of introduced tiger salamander alleles may not be feasible because adults may disperse over large distances and live for up to 11 years in underground burrows (Trenham et al. 2000). Further, eradication efforts under the Habitat Plan can only occur on Habitat Plan reserves. Most hybrids likely occur on private land, where access and management options are limited (Fitzpatrick and Shaffer 2007a).

Introduction of a few non-native alleles may change genetic similarity sufficiently to affect the legal status of California tiger salamander populations (Fitzpatrick et al. 2009). However, changes in morphological, ecological, or behavioral characteristics (that could potentially arise through introgression of even small amounts of genomic material may justify a change in legal status (Fitzpatrick et al. 2009; Fitzpatrick et al. 2010). For example, if future studies indicate that tiger salamanders with introduced alleles exhibit increased numbers of paedomorphs or increased predation rates on native pond species, new management actions, including eradication of hybrids, may be required to ensure that hybrids do not preclude the recovery of California tiger salamanders or adversely affect other native species.

It may therefore become necessary in the future to manage a subset of the population with allele frequencies beyond a set threshold as “not protected,” rather than verifying the genotype of each individual in the pond (Fitzpatrick and Shaffer 2007a).

The Implementing Entity will work with the Wildlife Agencies through the adaptive management process if monitoring data indicates that the initial management strategy is not adequate to meet the goals and objectives of the Plan.

## Monitoring

Hybrid index studies conducted by the University of California Davis in tiger salamander populations in California provide some baseline data for the study area. A baseline study will identify the distribution and level of hybridization in ponds and the presence of barred salamanders in the Reserve System (STUDIES-8). Baseline surveys will document presence of paedomorphs and identify non-native alleles and the frequency of those alleles present in a representative sample of salamander populations within the Reserve System. Future studies will focus

on how each non-native allele is physically expressed and the subsequent ecological impact of these alleles.

In years following baseline data collection, monitoring California tiger salamander level of hybridization will take place annually for a representative sample of wetlands and ponds within the Reserve System. Monitoring frequency could be modified with the approval of the Wildlife Agencies through the adaptive management process.

The results of monitoring will inform future management decisions made by the Implementing Entity and the Wildlife Agencies. The Plan will closely monitor the effects of this strategy on all affected covered species, not just the California tiger salamander. California red-legged frogs and western pond turtles commonly co-occur with California tiger salamanders and may be affected by habitat management proposed to address the California tiger salamander hybridization issue. Furthermore, grazing will play an important role in achieving the biological goals and objectives of many of the covered species (i.e., bay checkerspot butterfly). Draining of ponds for the benefit of California tiger salamanders has the potential of affecting the feasibility of grazing some portions of the Reserve System. If monitoring results indicate that the hybrid management strategy for California tiger salamanders is adversely affecting the conservation strategy for other covered species, the management plan will be modified through the adaptive management process with Wildlife Agency approval.

## Education and Research

The Implementing Entity will conduct education and outreach, provide technical assistance, and inform landowners of regulatory incentives (e.g., Safe Harbor Agreement) to restore, create, and maintain breeding habitat conditions on their land that favor native California tiger salamanders (POND-11). New nonnative salamander introductions are caused by humans and therefore could be decreased with a public education campaign. Public education will also be conducted to inform the public that the use of any salamander as bait in the State of California is illegal (POND-12).

The Plan will fund research to determine the distribution of, and ecological effects resulting from, introgression and interbreeding of native and non-native tiger salamanders (STUDIES-8). These studies will be coordinated with, and be complementary to, similar studies conducted outside of the purview of the Habitat Plan. With Wildlife Agency approval, the Implementing Entity will incorporate specific management prescriptions supported by this research, and research conducted by others, in the reserve unit management plans.

## **Fish Habitat Assemblage Data**

## Appendix L

# Fish Habitat Assemblage Data

## Introduction

The following section details the native and nonnative fish assemblages and in-stream aquatic habitat types throughout the major stream systems in the study area that are shown in **Figure 3-12** and described in detail in the section below. The figure illustrates the distribution of the native fish assemblages and riverine habitat types that occur in the study area.

## Fish Habitat Assemblages

To characterize the stream reaches for the purposes of the impact analysis and conservation strategy, a map was developed of native and non-native fish assemblages and aquatic habitat types throughout the major stream systems in the study area. Data was first developed to support SCVWD's Stream Maintenance Program. Dr. Jerry Smith of San José State University updated the map in July 2006 for the Science Advisors report of the Habitat Plan to reflect barrier removal and sampling results that occurred in the intervening years since the original map was created (Spencer et al. 2006). The map was then further revised and updated in 2007 by Dr. Smith and Jae Abel, a senior fisheries biologist at SCVWD. Jae Abel then adapted the map so that it corresponded to the new GIS stream data layer developed for the study area by SCVWD in early 2007. The stream categories emphasize habitat conditions for, and distribution of, steelhead trout and Chinook salmon. Ten categories were defined of fish assemblages and aquatic habitat types. These habitat categories are described as follows:

- **Estuarine.** Lowermost reaches of streams where conditions are saline and tidal (e.g., Guadalupe Slough, lower Guadalupe River, and lower Coyote Creek).
- **Cold Steelhead and Cold Steelhead—Extent Unknown.** A small portion of this habitat is on undammed tributaries, such as Tar, Bodfish, and Little Arthur creeks (tributaries of Uvas Creek); Cedar Creek (tributary of Pacheco Creek); Arroyo Aguague (tributary of Upper Penitencia Creek); and possibly the upper South Fork of Pacheco Creek. However, most of the remaining steelhead habitat in the study area is downstream of reservoirs on Los Gatos, Guadalupe, Alamos, Arroyo Calero, Coyote, Upper Penitencia, Llagas, Uvas, and Pacheco Creeks. The mapped stream segments in this category

normally provide an appropriate mix of: (1) relatively cool water (rarely above 22–24°C); (2) high stream flow to provide fast-water feeding habitat for steelhead; (3) relatively clean, coarse substrate for insect production; and (4) sufficient sun and water clarity to provide for algal growth (as a base of the food chain) and to allow steelhead to feed on drifting insects in fast water (Smith 1982, 2007; Smith and Li 1983). Much of the stream habitat in this category (downstream of reservoirs) is warmer than typical trout habitat, but the high summer stream flows, due to reservoir releases, allow steelhead to feed sufficiently on drifting insects to cope with the metabolic costs of the warmer water (Smith and Li 1983). Steelhead downstream of reservoirs in summer are found almost exclusively in fast-water habitat in riffles, runs, and heads of pools and often reach smolt size in one summer (Smith 1982, 2007; Smith and Li 1983). A variety of native fish species, including Pacific lamprey, are usually present in this habitat in upper tributaries and downstream of reservoirs.

- **Cold Trout and Cold Trout—Extent Unknown.** These are perennial habitats upstream of reservoirs where conditions are sufficiently cool to support resident rainbow trout, often with California roach, Sacramento sucker, and riffle sculpin present. Prior to reservoir construction, most of these habitats supported steelhead and possibly some salmon. Pacific lamprey is another anadromous species of concern that is presumed absent from this habitat upstream of the reservoirs. However, lampreys are able to ascend the spillway at Uvas Reservoir (Smith 1982) to utilize upper Uvas Creek. Resident trout are also present above natural and smaller artificial barriers on Smith, Bodfish, Little Arthur, and Upper Penitencia Creeks.
- **Warm Potential Trout/Steelhead.** These habitats are usually farther downstream of reservoirs than the cold steelhead reach and are often deficient in one or more of the four factors listed above for Cold Steelhead. Higher water temperatures increase steelhead food demands, often sufficiently to starve the fish. Variable year-to-year stream flows or reduced stream flows due to percolation reduce the fast-water feeding habitat that steelhead need to meet the metabolic demands of high temperature. Insect production is low due to poor substrate, turbidity, or low stream flow. Feeding is reduced by heavy shading or high turbidity. Management for increased stream flows or reduced water temperatures downstream of reservoirs in this zone may make the habitat more regularly suitable for steelhead. Often, warm-water native fish (see below) tend to dominate in this habitat type, with any juvenile steelhead scarce and/or strongly restricted to suitable fast-water feeding habitat.
- **Warm Native.** These habitats are dominated by native warm-water fishes, often including Sacramento sucker, hitch or California roach, Sacramento pikeminnow, threespine stickleback, and prickly sculpin. Most of the mapped reaches contain at least three to four of the above species as the minnow-sucker association of Smith (1982). North Fork Pacheco Creek (above the reservoir) and Upper Silver Creek (tributary of Coyote Creek) contain roach associations, dominated by California roach, with relatively scarce stickleback (Upper Silver Creek) or Sacramento sucker and prickly sculpin (North Fork Pacheco Creek). The third potential native warm-water fish community is the Sacramento perch (*Archoplites*

*interruptus*)/Sacramento blackfish community (Smith 1982). This low-gradient stream association is absent from the study area and from the rest of California because of the scarcity of Sacramento perch and the dominance of even high-quality downstream habitats by introduced fishes, including sunfishes and common carp (*Cyprinus carpio*). Foothill yellow-legged frogs and California red-legged frogs can occur in relatively undisturbed reaches of the warm native, cold steelhead, and cold trout zones.

- **Mixed Native—Salmon.** Chinook salmon currently spawn in Coyote Creek and the Guadalupe River and its tributaries. Some of the reaches they use are mapped as Cold Steelhead or Warm Potential Trout/Steelhead, indicating the higher quality year-round habitat that steelhead are potentially able to use for rearing. However, because Chinook spawn in early winter and juveniles migrate to the ocean in their first spring, Chinook are able to use habitats that turn very warm or have low water quality in summer. Most of these habitats also have a fish community composed of a mixture of native species (Sacramento sucker and hitch) and introduced species (carp and red shiner [*Cyprinella lutrensis*]).
- **Mixed Native.** These warm-water habitats contain a mixture of native and introduced species. This assemblage occurs in lower portions of Coyote and Llagas Creeks and Guadalupe River, the Pajaro River, and most pond and reservoir habitats. Native tule perch (*Hysterocarpus traski*) have apparently been reintroduced to Coyote Creek via the pipeline from San Luis Reservoir; they are present in the on-channel Ogier Ponds.
- **Managed Reservoir.** These artificial habitats provide warm-water lake conditions, a habitat type originally rare in the study area. These habitats are primarily occupied by sport fishes and other warm-water introduced species such as green sunfish, redear sunfish (*Lepomis microlophus*), pumpkinseed sunfish (*L. gibbosus*), crappie (*Pomoxis* spp.), bluegill (*Lepomis macrochirus*), largemouth bass, bullhead (*Ameiurus* spp.), white catfish (*Ameiurus catus*), and channel catfish (*Ictalurus punctatus*). Forage for the predatory fishes has usually included introduced threadfin shad (*Dorosoma petenense*), inland silverside (*Menidia beryllina*), golden shiner (*Notemigonus crysoleucas*), and crayfish. Some native fishes, including Sacramento sucker and Sacramento blackfish, can be abundant in the new habitats, but most native species do poorly when facing competition and predation from the introduced fishes.
- **Fish Scarce.** These habitats are normally dry during summer and fall. However, they may serve as migration routes for steelhead and other fishes and/or as reproductive habitat for rapidly developing amphibians such as tree frogs (*Pseudacris* [*Hyla*] *regilla*) or western toads (*Bufo boreas*).
- **No Data.** Fish species present are unknown, but may have fisheries values.
- **No Data/Probably No Value.** Fish species present are unknown, but because of location or habitat conditions the reach is unlikely to have habitat value for fish. A majority of the No Data or No Data/Probably No Value stream reaches are seasonal streams, extreme headwaters, or highly modified urban channels.

**Table 3-8** documents the relationship of the native fish communities to covered species and selected native fish.

## Habitat Plan Analysis Categories

The fish community designations were aggregated into two categories for analysis and conservation purposes related to the riverine land cover type under the Habitat Plan as follows:

- **Category 1—Fish bearing streams.** Includes all perennial and intermittent stream reaches that have sufficient flow to support cold and warm water native fisheries. Also includes all in-channel ponds and reservoirs. Also includes any Category 2 streams downstream of the Category 1 designation.
- **Category 2—Non-fish bearing streams.** All intermittent and ephemeral stream reaches that do not support native fisheries and are not downstream of reaches in Category 1. Also includes reaches with no data that likely do not support native fish. Would provide minimum protection to support water quality function under the Habitat Plan.

The stream categories (**Figure 3-12**) were derived from the fish community designations as a methodology for simplifying the impact analysis and conservation strategy while retaining the value of the underlying habitat information. This will allow for the underlying biological information to inform and guide the Habitat Plan, while allowing the categories that drive the conservation strategy and conditions on covered activities to provide maximum protection and conservation for habitats anticipated to improve during the permit term.

Canals and ditches were included in the riverine land-cover type due to their similar function to degraded streams and their very low acreage in the study area. Due to the nature of these man-made structures, canals and ditches are often managed for minimal vegetation to enhance the flow of water through the channels. However, canals that cross serpentine areas (e.g., Coyote Ridge, Santa Teresa Hills) often support several covered species including Santa Clara Valley dudleya, most beautiful jewelflower, smooth lessingia, Mt. Hamilton thistle, and California red-legged frog. Garter snakes and some ducks use canals and ditches throughout the study area.

Appendix M

# **Western Burrowing Owl Conservation Strategy**

# Appendix M

## Western Burrowing Owl Conservation Strategy

### M.1 Introduction

This appendix is provided as a supplement to the summary of the western burrowing owl conservation strategy in Chapter 5. The conservation strategy presented below has been constructed to offset impacts to western burrowing owl discussed in Chapter 4. Additional items relevant to the western burrowing owl conservation strategy are:

- Condition 15 in Chapter 6,
- monitoring commitments in Chapter 7,
- Stay-Ahead requirements for the burrowing owl conservation strategy in Chapter 8, and
- the burrowing owl fee in Chapter 9.

### M.2 Background

Nesting burrowing owls in the greater San Francisco Bay area and the South Bay area in particular, are a dwindling resource. In the early 1990s there were an estimated 150–170 breeding pairs in the San Francisco Bay area (DeSante and Ruhlen 1995; DeSante et al. 1997). It was estimated that these numbers represented a 53% decline from the previous census period of 1986–1990 (DeSante et al. 1997) and more recent numbers indicate that, if anything, the downward trend is increasing. In those estimates it was assumed that 75% of the San Francisco Bay area burrowing owl population occurred in Santa Clara County and nearly all of those owls were congregated around the southern edge of the San Francisco Bay (DeSante et al. 1997). Surveys in the early 1990s revealed that about a third (43–47 pairs) of Santa Clara County breeding pairs occurred inside what is now the Santa Clara Valley Habitat Plan study area (City of San José 2000).

The Plan proposes to undertake a suite of measures aimed at reversing the declining trend of the burrowing owl population in Santa Clara County. The conservation goal of the Plan, as implemented by these measures, is to establish a burrowing owl population in the permit area (the permit area includes the study

area and the extended study area for burrowing owl conservation) that is first stable, then increasing over time, while accounting for normal fluctuations in population levels. The general approach will be to increase the numbers, distribution, and connectivity of burrowing owl colonies in the permit area so that the potential for conservation success is high. This will be accomplished by using a phased conservation approach, initially focusing efforts on areas within 5 miles of an established breeding site while gathering data to inform future conservation efforts. Later phases, triggered as more resources are available and hopefully in response to initial successes, will focus on lands further out to allow for growth in both numbers and range. Initial techniques will include utilizing data gathering and analysis to inform management decisions, testing proposed management techniques and analytical approaches with scientific studies, acquisition (both permanent and temporary) of existing and potential breeding and foraging areas, management of burrowing owl habitat and, as a last resort, population augmentation techniques. These measures will be applied in four burrowing owl conservation regions, as described below.

## M.2.1 Burrowing Owl Conservation Regions

Opportunities to conduct meaningful burrowing owl conservation inside the Habitat Plan study area are limited because the most effective conservation measures must take place in near proximity to the remaining burrowing owl occurrences. Since those occurrences are clustered around the southern part of the San Francisco Bay and northern San José, there is little unused land available and that which is not built on has high land values. As a result the conservation focus for burrowing owls was expanded to include the entire South Bay region, in addition to the Habitat Plan study area (see Chapter 1, **Figure 1-2**). This *expanded study area for burrowing owl conservation* was determined following examination of movement distances of burrowing owls in the South Bay area. Movement distances have been inferred from encounters with burrowing owls that were banded at other locations in the South Bay area. The longest recorded movement of a banded burrowing owl in the South Bay area is 7.5 miles (12 km) (Harman and Barclay 2007; City of San José 2000), from the San José International Airport to National Aeronautic and Space Administration Ames/Moffett Federal Airfield (Moffett Airfield). That distance is important because it indicates a reasonable measure of dispersal distance, either for natal dispersal (birth site to nesting site) or breeding dispersal (movement between nesting locations). Planning conservation within a documented movement distance is valid to support the goal to increase the burrowing owl population and expand the distribution of burrowing owls in the South Bay area, and to proactively protect habitat that may support this expansion. For that reason, and due to the fact that most burrowing owl nest occurrences inside of the study area are on the northern edge of the study area (Barclay 2008), it was determined that conservation efforts for the burrowing owl should not be restricted to within the Habitat Plan study area, as data indicates the owls that will be the initial focus of the conservation efforts are most likely to move to the north, outside of the study area. As described in Chapter 1, take in the expanded study area will only be

authorized for burrowing owl conservation actions and not for other covered activities.

The study area has been divided into four burrowing owl conservation regions to more easily prioritize conservation actions (**Figure 5-10**). These regions are described below in order of current conservation priority.

- North San José/Baylands
- Gilroy
- Morgan Hill
- South San José

Conservation actions that will be employed to achieve the biological goals and objectives for burrowing owl will vary throughout the permit area. Generally, temporary and permanent management agreements will be put in place in the northern part of the study area and in the expanded study area. At least initially, limited habitat acquisition (permanent protection) and management will occur along the southern edge of the study area and more limited conservation activities will occur in the two middle regions because of the current lack of nesting burrowing owl colonies in these areas. If conservation actions in the North San José/Baylands region prove successful, and the number of breeding burrowing owls increases substantially, it is reasonable to assume the nesting burrowing owl population will expand into suitable habitat in the South San José, Morgan Hill, and Gilroy regions. Management of foraging and overwintering habitat will also occur on lands in the Reserve System, especially those that are dominated by grassland land covers and are located below 200 feet in elevation.

## North San José/Baylands Region

The North San José/Baylands region includes the City of San José, north and west of I-280/680, and extends around the southern margin of the San Francisco Bay to the Dumbarton Bridge (**Figure 5-10**). The remaining burrowing owl nesting colonies in the South Bay area are in this region. This region also has the greatest potential for population expansion because of its proximity to the remaining colonies. It is reasonable to assume that properly managed burrowing owl habitat in this region would be colonized (or recolonized) sooner than similar habitat in any other region.

Sites of importance for nesting burrowing owls within this region include the San José International Airport, San José/Santa Clara Water Pollution Control Plant, Mission College, the Shoreline Park and amphitheater area (Shoreline Park), Moffett Airfield, Santa Clara Valley Transportation Authority (VTA) Cerone bus maintenance yard, Tesla Plant (Fremont), Warm Springs (Fremont), and the Don Edwards San Francisco Bay National Wildlife Refuge (Don Edwards). With the exception of the VTA Cerone bus yard, none of these sites are under the jurisdiction of the Habitat Plan Permittees. Based on documented movements of burrowing owls in the South Bay area (Harman and Barclay 2007; City of San

José 2000) it is reasonable to assume that burrowing owls from any of these locations could disperse to any one of the other locations. Conservation efforts in the North San José/Baylands region will be the highest priority of the Implementing Entity because of the existing colonies and it has the greatest potential for expansion of the population.

The conservation strategy within this region will be three-fold. First, the Implementing Entity will attempt to stabilize the existing colonies to the maximum extent practicable. This will be done by acquiring land or, in circumstances where outright acquisition is not feasible but the location has significant value in the short term (i.e., San José International Airport, Shoreline Park, and Moffett Airfield), attempt to secure temporary management agreements to maintain nesting and foraging areas. Although these agreements will be temporary, they are expected to last long enough (10 years or more) to support meaningful burrowing owl management activities. Overall, the approach is to acquire or manage key lands where opportunities exist. Where acquisition is not possible, for whatever reason(s), the Plan recognizes that there may still be substantial benefit in maintaining existing breeding and foraging areas in the short term, until permanent protection can be established within the Reserve System. Therefore, use of permanent conservation easements, temporary conservation easements, or temporary management agreements on key lands may be the preferable option.

Maintaining and increasing breeding pairs in a highly altered environment such as exists around the San Francisco Bay area will require active land management, so assuring long-term management is essential for the persistence of burrowing owls in the South Bay area. Lands acquired or protected as described above will be managed to protect and enhance the owl populations. However, for sites that cannot be acquired or when acquisition is not as desirable a strategy as establishment of temporary or permanent management agreements, other approaches will be utilized. For example, at many sites in this region, public lands are, or could be, managed to support burrowing owls. At some of these sites, however, no permanent management assurances currently exist. For these sites, the Implementing Entity can carry out this strategy by providing stable, long-term funding or staffing for effective and consistent management and monitoring. With enhanced management, sites that already support breeding pairs could be improved to support more pairs. Alternatively, there may be opportunities to obtain permanent management agreements, without acquisition of the underlying land.

The second component of the conservation strategy in this region will be to attempt to increase the burrowing owl population and number of colonies within the jurisdiction of Plan Applicants. This will be done by acquiring land or securing temporary and permanent management (preferably permanent for this phase) agreements on lands that will be enhanced to attract new burrowing owl pairs. Many sites in the region may not support burrowing owls consistently because vegetation or other factors (e.g., predators) render them unsuitable. With proper management, sites within the dispersal distance of breeding locations will be managed to attract new breeding pairs.

Public lands where enhanced management may be secured to meet the Implementing Entity's population goals in this region are:

- San José International Airport (including the VHF Omnidirectional Range [VOR] communications parcel adjacent to U.S. 101);
- San Jose/Santa Clara Water Pollution Control Plant, including buffer lands;
- Alviso;
- SCVWD levees not critical for flood protection (e.g., Pond A4);
- VTA Cerone bus maintenance yard; and
- Closed landfills within San José and other cities that primarily support annual grassland. If managed properly, these areas could provide foraging habitat for burrowing owls. In some cases, California ground squirrels have recolonized these sites, providing nesting opportunities for burrowing owls as well.

Some private land may also be suitable for management agreements to help meet Plan goals.

The final component of the strategy in this region is long term and will consist of attempting to extend the burrowing owl range beyond the existing localized area. It is intended that this range expansion will lead to an increase in the overall number of burrowing owls and colonies. The primary mechanism to accomplish this goal will be to acquire, either in fee title or through permanent conservation easements, or management agreements, areas outside of currently occupied nesting habitat to accommodate the population expansion. These areas will then be enhanced to provide suitable burrowing owl habitat. Suitable sites for habitat enhancement may include, but are not limited to the following.

- Moffett Airfield.
- Don Edwards.
- City of Sunnyvale San Francisco Bay front lands (Baylands).
- City of Palo Alto Baylands.
- City of Mountain View Shoreline Park.
- Golf courses (e.g., in Santa Clara along Tasman Road)—many golf courses in the South Bay Area provide foraging and, at times, nesting habitat for burrowing owls. This often occurs around the edges of a golf course, in areas outside of the fairways, where there is more natural vegetation (i.e., the “rough”).
- Various private lands in the City of Fremont—Warm Springs District.
- Various closed landfills.
- Various Baylands in the cities of Milpitas and Fremont.

Although burrowing owl conservation actions in the sites listed above could contribute to the burrowing owl conservation strategy, not all of the locations

listed above will be eligible to be counted toward the Habitat Plan's Reserve System acquisition commitments, since protection and management in perpetuity cannot be guaranteed for most of these sites. However, the conservation strategy for this species explicitly recognizes that there can be substantial interim benefit in protecting and managing these areas for the longest period possible, in order to provide time to allow the Reserve System to be assembled and for the expansion of the burrowing owl range within the Habitat Plan Reserve System.

## Gilroy Region

This region includes the valley floor in the southern tip of the study area surrounding the City of Gilroy (**Figure 5-10**) to the Pajaro River. This region has a moderate-high potential for nesting burrowing owls because of burrowing owl occurrences near the Pajaro River. The primary conservation actions in this region will be to attract burrowing owls into the region from neighboring San Benito County, where nesting burrowing owls have been documented in low numbers during surveys in 2008 and 2009 (Barclay 2008). This will occur through acquisition of or management agreements on potential burrowing owl nesting habitat (or occupied nesting habitat if a colony is discovered) and enhancement through improved management. Currently, most of the land along the San Benito County line is managed intensively for row crops, which is generally not suitable for nesting owls although the edges of fields and uncultivated areas can provide foraging habitat.

There have been no documented nesting burrowing owls within this region since the early 1990s. Lands in this region are within the expected dispersal distance of burrowing owls nesting in northern San Benito County (Barclay 2008), so with proper management the potential exists for burrowing owls to colonize reserve lands protected in this region. There may also be opportunities to implement or improve management on public lands in the Gilroy region to attract and maintain burrowing owls. These cost-effective measures may be appropriate at the South County Water Treatment Plant in Gilroy, or other sites.

## Morgan Hill Region

This region includes the valley floor between the northern boundary of the City of Gilroy and the southern boundary of the City of San José (**Figure 5-10**). The region extends west and east to the toe of the surrounding hills. While there seems to be an abundance of burrowing owl habitat in this part of the study area no burrowing owl nests have been observed in this region since 2002 (DeSante et al. 2007; Townsend and Lenihan 2007; Barclay 2008). Before 2002, reports of nesting owls in this region were sporadic. As a result, this region has only a moderate potential to provide expansion for the burrowing owl population from the South Bay area.

During the Plan permit term, the primary purpose of burrowing owl conservation in this region will be to provide connectivity between populations in the North San José/Baylands Region and the Gilroy Region. It is hoped that burrowing owls will eventually return to this area in significant numbers. Potential nesting habitat will be acquired or placed under management agreements in this region to attract burrowing owls. When a parcel is acquired for the Reserve System that has burrowing owl habitat present, the management plan for that parcel will specify management actions that enhance the burrowing owl habitat.

## South San José Region

The South San José region includes the remainder of the City of San José south and east of I-280/680 (**Figure 5-10**). This region extends to the southern urban edge of San José and into the eastern hills. It is unknown what population levels were in this region historically, and there are currently very limited conservation opportunities in this part of the study area due to the urban environment, poor connectivity to populations that could provide colonizers and the low numbers of nesting burrowing owls in the recent past (Barclay 2008; California Natural Diversity Database 2009). Typically the number of burrowing owls in this region ranges from 0–2 adult burrowing owls. During surveys conducted from 2008–2009, one nesting pair was observed (on vacant land next to Meadowfair Park).

Expected impacts to occupied nesting burrowing owl habitat will be low or absent from this region because few, if any, nesting owls remain.

The primary goal of burrowing owl conservation in the South San José Region is to provide stepping-stone connectivity between the North San José/Baylands region, and the Morgan Hill region. The functionality of any connectivity through this area is constrained because it is mostly a highly urbanized environment. Due to the limited amount of suitable habitat and the isolation of existing habitat patches the Implementing Entity will not only pursue land acquisition in this region to secure conservation but will also attempt to reach permanent or temporary management agreements with public or private landowners to retain suitable habitat for burrowing owls.

### M.2.2 Population Performance

As part of the process to determine a viable conservation plan for burrowing owls in the Plan, it was decided to utilize a count-based population viability analysis (PVA) to determine the probability of persistence of three burrowing owl nest colonies in the South Bay (**Appendix N**). This analysis was completed on the three largest remaining burrowing owl colonies in the South Bay area: Moffett Airfield, San José International Airport, and Shoreline Park using survey data of adult burrowing owls from the 11-year period, 1999–2009. These sites were chosen because they are the primary remaining population clusters and because

data was available for the period of time recommended for the analysis (i.e., at least 10 years). The intent of the analysis was to quantify population size, trend, growth rate, and variance in the three burrowing owl colonies and to evaluate the probability of persistence of these colonies (individually and combined) during that 11-year period. Using those data, a PVA was generated to estimate the risk of future extinction based on the behavior of the data during the 11-year period. It is assumed that changes in population performance at these three colonies are indicators of changes that could occur in the South Bay burrowing owl nesting population as a whole if it were under more of a managed condition. Therefore, the population performance at these three sites can be used as an index for population performance for burrowing owls in the Habitat Plan study area.

All three colonies showed declining population trends during the 11-year period from 1999–2009. The colonies at San José International Airport and Moffett Airfield showed very similar magnitudes and variance of decline, while Shoreline Park showed an even greater magnitude and variance of decline. The PVA model predicts similar probabilities of extirpation for the colonies at San José International Airport and Moffett Airfield, while Shoreline Park reflects an even higher probability.

The standard that was used to represent effective extirpation is the probability of reaching a quasi-extinction threshold of two adult owls. Quasi-extinction in this case is defined as the point at which the breeding colony becomes essentially non-functional (two adults). San José International Airport and Moffett Airfield showed similar probabilities of quasi-extinction, with an unacceptably high chance of extinction (95%) by Year 22. Shoreline Park showed a probability of reaching the quasi-extinction threshold of two adults, with an unacceptably high<sup>1</sup> chance of extinction (95%) by Year 10. This is likely due to the smaller size of this colony. The probability of quasi-extinction for the combined populations was set at six adults for all three colonies (representing two adults at each colony). The combined sites had an unacceptably high chance of extinction (95%) by Year 18. See **Appendix N** for more details on the methods and results of this analysis.

## Population Size

In order to develop a burrowing owl population size goal for the Habitat Plan, the annual population size of adult owls was artificially increased in a statistical model to determine the rate at which the numbers of adult burrowing owls at the three baseline colonies (San José International Airport, Moffett Airfield, and Shoreline Park) would need to increase and over what period of time to change the PVA probability of extinction trend from a negative growth rate to a positive growth rate. It was determined that if currently measured population characteristics held true (i.e., growth rate and variance were constant) changing the overall number of adult burrowing owls in this type of model did not change

---

<sup>1</sup> The point at which probability of quasi-extinction reaches an “unacceptably high” level is described in the PVA (**Appendix N**).

the probability of persistence significantly (**Appendix N**). Instead, changing the growth rate from negative to positive required an incremental, annual, steady increase in the number of adult burrowing owls over a number of years. Therefore, for the purposes of this Plan, growth rate is a more correct predictor of persistence than an ultimate population size.

The most recent survey year that was considered in the PVA was 2009. During that year there were 51 adult burrowing owls observed at the three nest colonies under study. This analysis focuses on the number of adult burrowing owls rather than breeding pairs or juveniles (for a complete discussion of this see **Appendix N**). In order to change the population trend at the three colonies from negative to positive, within a 10-year time period there would have to be an increase of three adult owls per year combined at the three sites. Based on the data set used in the PVA, quasi-extinction at the three PVA colonies would occur in 18 years. By setting population growth goals that would change the growth rate from negative to positive by Year 15, the strategy aims to avoid a situation where the South Bay burrowing owl population gets too low to recover. A period of at least 10 years is also needed to allow time for collection of data at occupied nest sites in the permit area and integration of that data into the PVA model.

## M.3 Biological Goals and Objectives

The primary goal of the conservation strategy is to increase the size and sustainability of the breeding population and increase the distribution of breeding and wintering burrowing owls in the study area and the expanded burrowing owl conservation area. The PVA demonstrates that the overall number of adult burrowing owls in the South Bay area is less important than the trend in population numbers and the variability in the number of owls from year to year. An unsurprising conclusion is that a growing or stable population is more likely to persist than a widely fluctuating population.

Based on this conclusion, the Implementing Entity will establish a positive growth trend in the permit area by Year 15 of the permit term and maintain the overall positive growth trend thereafter; manage 5,300 acres of modeled occupied and potential nesting habitat in the permit area; and protect and manage 21,310 acres of modeled overwintering habitat (**Figure 5-10**). This will be accomplished by targeting protection and management of grassland or barren land (as described in Chapter 3 and shown in **Figure 3-10**) with less than 25% slope in tracts that meet minimum species spatial requirements. When considering the recovery of the burrowing owl in the Habitat Plan permit area, the ultimate regional goal is to have a burrowing owl population determined by the PVA to be stable. In practical terms, we define this goal as being met by achieving a positive growth rate by Year 15 of the Plan using annual data collected from active nesting colonies in the South Bay area for which adequate data is available and determined to be stable enough to not artificially skew the results. Year 15 was chosen to allow adequate time for the conservation actions

to have a measureable effect and to provide a buffer on the 10-year goal discussed above. In addition, if counts of adult burrowing owls begin in Year 1 of implementation, those data cannot reliably be used in a PVA until Year 10 of implementation. Setting the goal of achieving a positive growth rate by Year 15 allows for the inclusion of sites in the South Bay area be incorporated into a PVA analysis, and apply an adaptive management approach if it is discovered that positive results are not being reached at Year 10.

The most likely way to achieve the Year 15 positive growth rate will through an average increase in the number of adult burrowing owls at San José International Airport, Moffett Airfield, and Shoreline Park each year during the Year 15 time period. These three sites are the focus because there was enough data (recommended 10 years) at each site to perform a PVA. Continuing to track the number of adult burrowing owls at each of these locations will give the Implementing Entity the most accurate assessment of how the burrowing owl population is performing and whether the goals for the number of adult burrowing owls is being met each year. Additional data will be collected annually at VTA Cerone bus yard, the San Jose/Santa Clara Water Pollution Control Plant buffer lands, and any other nest sites found during Plan implementation, but that data will not be useful for assessment using a PVA until ten years of data is collected at the site.

In addition to monitoring population changes in adult owls, the Implementing Entity will enhance grassland or barren land (as described in Chapter 3 and shown in **Figure 3-10**) on which management agreements have been placed and on Reserve System lands that are flat or moderate slopes (<25%). In order to increase the chance that the sites will be used by owls, areas will be targeted within 5 miles of an established breeding site in the permit area (i.e., San José International Airport, Reid Hill View Airport, San Jose/Santa Clara Water Pollution Control Plant buffer lands). Acquisition, enhancement, and restoration conservation actions identified for grasslands (see Section 5.3.3 *Grassland Conservation and Management*), valley oak woodlands (see Section 5.3.5 *Oak and Conifer Woodland Conservation and Management*), and seasonal wetlands (see Section 5.3.7 *Wetland and Pond Conservation and Management*) are intended to benefit western burrowing owl through breeding and foraging habitat conservation and management.

An adaptive management approach for determining what types of conservation actions will be employed and where conservation funds will be spent is critical since management activities are likely to change often, due to rapidly changing circumstances, both negative and positive. Depending on a number of factors, the priorities for conservation monies may shift (see *Setting Conservation Priorities*, below). Priorities may also shift through the adaptive management process if additional colonies are discovered during the permit term.

In order to achieve Plan goals during the permit term the Implementing Entity will carry out the following generalized conservation actions.

1. Protect existing colonies through fee title acquisition, purchase of a conservation easement, or other management agreements (San José

International Airport, Moffett Airfield, Shoreline Park and others, known or unknown), managing the sites for long-term nest viability.

2. Protect foraging habitat, through fee title acquisition, purchase of conservation easements, or other management agreements (San José International Airport, Moffett Airfield, Shoreline Park and others, known or unknown), ensuring proper burrowing owl management on those sites.
3. Protect through fee title acquisition, purchase of a conservation easement, or other management agreements, currently unoccupied areas that have potential nesting habitat and are within the expected dispersal distance of nesting burrowing owls.
4. Protect through fee title acquisition, purchase of a conservation easement, or other management agreements, locations outside of the 7.5-mile dispersal distance in anticipation that these lands will be needed in the future for nesting, foraging, and connectivity between colonies as the burrowing owl population expands beyond its current distribution.
5. Carry out data collection, analysis and controlled experiments to ensure the most appropriate techniques will be used and are being used.
6. Manage habitat areas that may support burrowing owls.
7. If the conservation strategy is implemented as planned but the number of adult burrowing owls fails to meet the annual increase of at least three adult owls each year at the annual survey sites described in Section 7.3.3 *Species Level Actions* subheading *Western Burrowing Owl (Group 1)* the Implementing Entity will propose more active conservation methods to the Wildlife Agencies, such as population augmentation to provide a boost to local population numbers. Active methods utilized will be supported by data gained from pilot studies. Any changes to the conservation strategy (i.e., adaptive management) must be approved by the Wildlife Agencies prior to implementation.

The specific burrowing owl conservation plan is comprised of conservation actions that are grouped into three “tiers” of priority. Each tier is discussed in detail below but generally consists of:

- **Tier 1 conservation actions** are designed to stabilize the existing population by protecting and/or managing occupied burrowing owl nesting habitat. Tier 1 actions may indirectly increase the numbers of owls in extant colonies. Tier 1 conservation actions will take place initially in the North San José/Baylands Region where owls currently occur. Tier 1 conservation actions will occur immediately.
- **Tier 2 conservation actions** are designed to facilitate growth and expansion of existing colonies, the number of colonies, and the range of the species in the permit area by protecting and managing potential burrowing owl nesting habitat in all portions of the permit area. Tier 2 conservation actions will also take place immediately and initially in the North San José/Baylands Region where owls currently occur.

- **Tier 3 conservation actions** consist of more experimental and active methodologies such as population augmentation and owl relocation within the permit area to increase owl numbers and expand distribution. Tier 3 actions will be implemented in response to population performance at the three index sites (Shoreline Park, San José International Airport, and Moffett Airfield) but these actions could occur in any of the burrowing owl conservation regions. These actions will be coordinated with the Wildlife Agencies and will only be implemented upon their approval.

Funds collected for burrowing owl conservation actions related to occupied and potential nesting habitat come from the Habitat Plan land cover fee and the burrowing owl fee. It is anticipated that funds will be obtained from other sources, such as non-profits and State and Federal grants, to augment specific conservation actions, including research efforts. The land cover fees will support acquisition and management of land in the Reserve System which will assist with all three tiers of conservation. The burrowing owl fee will be used to complete conservation actions in all three tiers as well, but if the population trend is downward, use of the burrowing owl fee could shift as described below. The types of conservation actions that burrowing owl fee funds will be used for will depend on the conservation need at the time the accumulated funds are spent, and may include activities in all tiers. However, in the short-term<sup>2</sup>, funds collected from the burrowing owl fee will be used for two purposes: protection and management of occupied burrowing owl habitat (Tier 1), and data collection (e.g., annual surveys).

Through the course of the permit term these three tiers of conservation actions may occur in any of the four burrowing owl conservation regions. Initially, Tier 1 conservation actions will only occur in the North San José/Baylands region because occupied burrowing owl nesting habitat currently only occurs in this region. Should burrowing owls begin to nest consistently in other regions of the permit area, Tier 1 conservation actions may occur in those areas as well. Tier 2 conservation activities will occur throughout the permit area, in all four burrowing owl conservation regions because potential burrowing owl nesting habitat occurs in all four regions. Initially, Tier 3 conservation activities will only occur in the North San José/Baylands region since this is where existing nest colonies occur, and there is the greatest potential for effective implementation of these measures, should they become necessary. Tier 3 conservation actions may also occur in other regions later in the permit term if nesting burrowing owls establish there on their own.

## **M.3.1 Setting Conservation Priorities**

The Implementing Entity will determine how burrowing owl conservation funding will be allocated. Acquisition in fee title or conservation easement will always be the preferred strategy. However, given the unique circumstances for

---

<sup>2</sup> Until at least two annual surveys (one to establish the baseline and one year to determine whether or not the population is increasing by three birds per year) have been completed.

the burrowing owl, the conservation strategy for the burrowing owl includes more flexibility than is provided for the conservation strategy for other covered species. The default assumption is that funds generated from the burrowing owl fee will be used to acquire and manage occupied and potential burrowing owl nesting habitat in the South Bay area through fee title, conservation easements, or management agreements. Other funding sources may also be used for this purpose, but monies from the burrowing owl fee will be earmarked for this purpose, as well as for other burrowing owl conservation actions. The selection criteria for how acquired or managed parcels will be chosen are discussed below (see Section M.4.3). Burrowing owl fees will be used wholly to acquire and manage occupied or potential nesting habitat, as long as the PVA population curve indicates a positive growth. During the first 10 years, this will be assumed to be occurring as long as there is sufficient annual increase of at least three adult owls per year cumulatively at the annual survey sites (e.g., Moffett Airfield, Shoreline, San José Airport, VTA Cerone bus yard, and San Jose/Santa Clara Water Pollution Control Plant buffer lands). During the first 10 years, burrowing owls will be surveyed inside the permit area to begin to build a dataset that can be used in a PVA for the South Bay population starting in Year 10. From that point forward the PVA will be based on all sites surveyed in the South Bay area, both inside and outside of the permit area, for which sufficient data exists. This will give the most accurate picture of population viability in the South Bay and will better inform whether the conservation strategy is working. Conservation action prioritization will be based on available funding and the numbers predicted by the PVA model necessary to achieve positive growth.

The first year of annual surveys will determine the baseline population of burrowing owls in the permit area. If during Plan implementation the cumulative annual growth rate is below the three-owl threshold at the annual survey sites, or after more colonies are added to the model, below whatever number of owls is predicted by the model to achieve positive growth, then 50% of the revenue generated from the burrowing owl fee will be shifted from Tier 1 and 2 conservation actions to Tier 3 conservation actions. The decision about funding allocation for Tier 1 and 2 conservation actions versus Tier 3 conservation actions will be made following the annual survey that begins during the second full year of Plan implementation. The numbers of adult burrowing owls annually at the three index sites will be compared to the number of adult burrowing owls observed at the three sites during the first full year of implementation. Following the assessment during year two, the change in the number of adult burrowing owls at the three sites will be documented annually and the trend recorded. If the goal of an increase of at least three adult burrowing owls is not being met, then the money collected from burrowing owl fee will be split 50/50, between Tier 1 and 2 vs. Tier 3 conservation actions.

## **M.3.2 Burrowing Owl Conservation Priorities**

### **Tier 1 Conservation Actions**

1. Protect and manage occupied burrowing owl nesting habitat (an active nest and foraging lands within 0.5 mile of the active nest).

In order to identify occupied nesting habitat, the Implementing Entity will coordinate annually with survey efforts conducted at known nesting sites in the permit area including surveys conducted at San José International Airport, Moffett Federal Airfield, Shoreline at Mountain View, VTA Cerone bus maintenance yard, and San Jose/Santa Clara Water Pollution Control Plant buffer lands. Additional locations will be surveyed in subsequent years as new colonies are formed or discovered over the permit term. The Implementing Entity will coordinate with survey staff at the first three locations to obtain data from ongoing annual survey efforts and will provide guidance on the survey information required to inform regional data collection. The Implementing Entity will be responsible for conducting surveys at the last two locations (and any new colonies that may be discovered during the permit term) and will use the same methodology across sites to ensure consistency. All surveys will be conducted consistent with California Burrowing Owl Consortium methodology (California Burrowing Owl Consortium 1993). Data collected from the annual survey sites will be used to track the number of adult burrowing owls and to assess reproductive status. Information will contribute to a rolling population viability analysis in the region. Collectively, the data will inform the adaptive management of this species and will help prioritize use of funds for burrowing owl conservation under the Plan. The first annual survey will occur during the first full year of Plan implementation and each year thereafter.

The protection of occupied and potential nesting habitat will be tracked in the same manner as other land cover types, discussed in Section 8.6.1, to ensure that impacts are occurring in rough step with habitat goals based on the necessary population increase to allow for recovery.

2. Increase survival rates at existing nest colonies through one or more management actions including, but not limited to:
  - a. protection of nests by controlling access and maintaining fencing,
  - b. predator control,
  - c. habitat management to increase prey availability,
  - d. cessation of inappropriate rodent control (e.g., application of rodenticides, hunting, or trapping) on-site and/or implementation of activities that would enhance burrowing mammals.
3. Where feasible, fund management activities on the three index sites (San José International Airport, Moffett Airfield and Shoreline) to benefit burrowing owls.

## Tier 2 Conservation Actions

Tier 2 conservation actions will be initiated during the first year of implementation. These actions will require several years to complete and will be initiated upon Plan implementation.

1. During the first 3 years of implementation, survey all undeveloped parcels within 7.5-miles of documented nest colonies in the North San José/Baylands Region and complete an opportunities and constraints assessment of each, relative to the potential of the parcel to function as a burrowing owl reserve in the future. Assign parcels a high, medium, or low priority for burrowing owl conservation.
  - a. High: parcel with documented nesting burrowing owls in the previous 3 years and grassland or barren land cover, which can be managed (vegetation height) to be favorable to burrowing owls and is currently occupied by ground squirrels or has other suitable nesting burrows. Existing landowners willing to enter into management agreements and current land uses that are compatible with burrowing owl habitat requirements would be ranked higher than those that do not meet these criteria.
  - b. Medium: parcel with no history of burrowing owl occupancy but with grassland or barren land cover, which can be managed (vegetation height) to be favorable to burrowing owls and is currently occupied by ground squirrels or has other suitable nesting burrows.
  - c. Low: parcel with grassland or barren land cover type that can be managed (vegetation height) to be favorable to burrowing owl but lacks ground squirrels or other suitable nesting burrows.
2. The Implementing Entity will also coordinate with other South Bay local governments, special districts, and non-profit organizations every 3 years to assess status of the burrowing owl population in the study area and the expanded study area for burrowing owl conservation. These survey efforts are aimed at identifying occupied and potential burrowing owl habitat in the four burrowing owl conservation regions. The focus of this larger survey effort is to document population expansion into new areas. This 3-year survey will help determine whether the range of nesting burrowing owls in the study area and expanded study area for burrowing owl conservation is stable and, possibly, expanding. Analysis of the survey results will encompass the areas surveyed annually, areas with historical or recent occurrences of nesting burrowing owls, and areas with highly suitable habitat that has not been occupied in the past.
3. Protect and/or manage potential or occupied burrowing owl nesting habitat as described above.
4. Conduct two meetings annually of burrowing owl survey partners. The first meeting will be in January, prior to the burrowing owl nesting season to coordinate with surveyors and ensure that all appropriate locations are surveyed. The second meeting would be in September, following the

burrowing owl nesting season, to gather data from surveyors and discuss potential changes in survey protocols.

## **Tier 3 Conservation Actions**

1. With Wildlife Agency approval, implement a program to increase reproductive success of burrowing owls in the South Bay area. General success criteria for the program will be defined in close coordination with the Wildlife Agencies and set prior to its implementation, during the surveys described in Tier 2, and based on the success or failure of the program, interim checkpoints will be established to determine if/when the program should cease.
2. Study the feasibility of population augmentation activities including the following.
  - a. Initiate a pilot reintroduction program and study the success of the effort and the feasibility of replicating the effort elsewhere. Potential locations for a pilot study include, but are not limited to:
    - 1) San José International Airport VOR site (radio tower),
    - 2) fenced portion of San Jose/Santa Clara Water Pollution Control Plan buffer lands,
    - 3) fenced portion of Don Edwards,
    - 4) existing burrowing owl mitigation area in the City of Santa Clara at the end of Great America Parkway, and
    - 5) Parts of Shoreline Park designated burrowing owl habitat under an approved Burrowing Owl Management Plan.
  - b. Initiate a pilot study to determine other methods to increase reproduction of local burrowing owls. These methods may include but are not limited to:
    - 1) protect nest sites to reduce predation on eggs and young,
    - 2) supplemental feeding of nesting females and young,
    - 3) forced re-nesting or double-clutching of owls in captivity, and
    - 4) foster nestlings to maximize brood size.

If studies have not been completed to justify the use of one or more of these techniques, then funds shifted to Tier 3 will be used first to plan and complete those studies.

## **M.4 Habitat Management and Enhancement**

### **M.4.1 Occupied and Potential Nesting Habitat**

The Plan assumes that 5,300 acres of occupied and potential nesting habitat will be managed for the conservation strategy. This land may be acquired in fee title or conservation easement, or it may be managed under temporary or permanent management agreements. At a minimum, 600 acres of the 5,300 acres must be protected under a conservation easement as part of the Reserve System, and this 600 acres must be occupied nesting habitat.

#### **Assumptions for Calculating Amount of Conservation Needed**

1. In order for the South Bay burrowing owl population to be stable or increasing, an additional three owls (1.5 breeding pair) will need to be recruited into the population each year.
2. A breeding location (nest) requires a minimum of 140 acres of foraging habitat surrounding the nest site. If an additional 1.5 breeding pairs are recruited into the local population each year an additional 210 acres ( $1.5 \times 140 = 210$ ) would need to be managed each year to support that expansion.
3. Many of the areas where conservation opportunities exist are already owned and managed by Permittees. It is assumed that some conservation actions will occur on those lands to benefit burrowing owls outside of the Plan requirements. As such, the acres of new lands that will be acquired or put under management agreements was reduced by 15%.
4. Owls from multiple nest sites use the same foraging habitat (i.e., breeding territories overlap). The total estimate of land that needs to be acquired and/or managed for burrowing owl population growth has been reduced by 20% to account for this overlap in foraging habitat.
5. Utilizing survey data from 2009 the number of adult burrowing owls for Shoreline Park (6), Moffett Airfield (26), and San José International Airport (19) was 51 adult burrowing owls. An additional 19 burrowing owls were observed during surveys in 2008 in other parts of the Habitat Plan study area. This total of 70 adult burrowing owls in the South Bay area is a good estimate of the baseline number of adult burrowing owl in the South Bay area. Of those 70 owls, 38 (or 54%) were inside of the Habitat Plan study area.
6. It is assumed that even though 54% of the burrowing owl population currently resides inside the Habitat Plan study area, the Habitat Plan conservation strategy will address the habitat needs of 70% of the population going forward. This additional commitment is an acknowledgement of habitat lost in the north San José area in the past and demonstrates a

commitment to recovering the species in the South Bay area during the permit term.

7. If three burrowing owls (1.5 breeding pair) are recruited to the population each year, a total of 220 (70 baseline+150 new) would be attained over the 50-year permit term. Based on a commitment to support 70% of the habitat needed for a successful South Bay burrowing owl population, 154 (70% of 220) adult burrowing owls would be supported by lands managed by the Implementing Entity by the end of the permit term. Therefore adding 116 owls (154 total – 38 baseline) would be the responsibility of the Implementing Entity. Those additional 116 adult burrowing owls (58 breeding pair) would require 140 acres of foraging habitat per pair, for a total of 8,120 acres.
8. The 8,120 acre requirement would be reduced by 15% (see number 3 above) to give credit for additional conservation actions and by 20% (see number 4 above) to account for overlapping foraging habitat between breeding pairs  $(8,120 - (8,120 * 15\%) - (8,120 * 20\%) = 5,278$  acres which is rounded to a 5,300-acre commitment in the Habitat Plan).

## Nesting Habitat Acquisition and Management

Based on these assumptions, the Implementing Entity will manage a minimum of 5,300 acres for the western burrowing owl nesting habitat (occupied and potential) by Year 45. Of this acreage, a minimum of 600 acres of occupied nesting habitat must be protected in fee title or conservation easement. For the remaining 4,700 acres, land acquisition (fee title or easement) or management agreements may be used. The Implementing Entity will prioritize land acquisition over management agreements. All 5,300 acres of western burrowing owl nesting habitat will be acquired or under a permanent management agreement by Year 45.

Management agreements may be used in place of land acquisition on up to 4,700 acres, if the specified regional targets cannot be met through land acquisition. During the permit term, temporary management agreements may be put into place rather than permanent management agreements. Temporary management agreements (e.g., 10–20 year agreements as opposed to agreements in perpetuity) may be used to protect nesting habitat on areas not immediately planned for development as long as the amount of land permanently protected in fee title or conservation easement is consistent with the Stay-Ahead provision (Chapter 8, Section 8.6.1 *Stay-Ahead Provision*, subheading *Rough Proportionality and Stay-Ahead for the Burrowing Owl Conservation Strategy*). By Year 45 of the permit term, all management agreements must be permanent.

The management agreements must be legally binding documents to which the Wildlife Agencies are parties. Their establishment will follow a process similar to land acquisition described in Chapter 8, Section 8.6 *Land Acquisition*. The management agreements will be consistent with the land acquisition process; however, the Implementing Entity would work with the land owner to establish

the management agreement rather than acquiring the land in fee title or with a conservation easement. The duration and management requirements will be agreed upon by all parties and specified in the management agreement document. For the permanent management agreements, management must be assured in perpetuity. For temporary management agreements, management must be assured for the duration of the agreement. As parties to the management agreements, the Wildlife Agencies will have review and approval authority.

The opportunities for burrowing owl conservation are discussed for each burrowing owl conservation region in Section M.2.1 (above) and summarized in Chapter 5. Since the North San José/Baylands region is the most important for burrowing owl conservation and has the most immediate conservation opportunities, 70% (3,700 acres) of the total land management should occur in that region. These management agreements would occur inside the permit area, including the expanded study area. In addition, 15% (800 acres) of the total land managed would occur in the Gilroy region. The remaining 15% should remain flexible and could occur in any of the regions, but we recommend that 5% (270 acres) occur in the South San José region and 10% (530 acres) occur in the Morgan Hill region.

## M.4.2 Overwintering Habitat

There are 132,770 acres of burrowing owl overwintering only modeled habitat within the study area. A total of 28,517 acres (21%) of overwintering modeled habitat are located in Type 1, 2, or 3 open space with 12,584 acres (9%) of that habitat permanently protected as Type 1 open space. The Plan proposes to acquire a minimum of 17,000 acres of modeled overwintering habitat for the Reserve System. In addition, 4,310 acres of overwintering modeled habitat for western burrowing owl will be added to the Reserve System from existing open space. Incorporation of County Park lands into the Reserve System (**Table 5-5** and **Figure 5-4**) will benefit the species by providing opportunities for habitat enhancement and long-term monitoring. All of these acquisitions and additions will increase the proportion of protected overwintering modeled habitat in the study area to 26% in Type 1 open space and 34% in Type 1, 2, or 3 open space (**Table 5-17**).

Modeled overwintering habitat for western burrowing owl will be permanently preserved, managed, and enhanced throughout the Reserve System in all major watersheds in the permit area. Overwintering habitat will be protected in low elevation grassland valleys in the Diablo Range that currently support California ground squirrels, have supported California ground squirrels since 1997, or are adjacent to lands with existing California ground squirrel colonies (LAND-G8). Low elevation valleys within the Reserve System that are located on the valley floor or in the Diablo Range will be managed to benefit nesting and overwintering burrowing owls. Some locations on the southern edges of the City of San José could support burrowing owls in the future. In addition, several acres will be acquired in the southern part of the permit area in the Pescadero watershed that could be converted to annual grassland and managed for western

burrowing owls. Nearly all land acquisition in areas dominated by annual grassland has the potential to benefit overwintering owls. Most of that land acquisition will occur along Coyote Ridge, west of Chesbro Reservoir, west and east of Calero Reservoir, and between Henry W. Coe State Park and the San Benito County line. This land acquisition has been primarily targeted for other covered species but will have incidental conservation benefit for western burrowing owls, especially during the winter months.

### **M.4.3 Reserve System Lands Selection Criteria**

Land that is acquired through fee title purchase or easement to meet biological goals and objectives for burrowing owl nesting and overwintering habitat in the Habitat Plan permit area will be selected using the reserve design principles in Chapter 5. All lands or easements will be acquired from willing sellers using the process defined in Chapter 8.

#### **Location Criteria**

When identifying and acquiring the 600 acres for permanent protection and enrollment into the Reserve System, the Implementing Entity will use the following guidelines.

1. The Implementing Entity will preferentially select a parcel that is inside of the Habitat Plan study area over a parcel that is inside of the expanded study area for burrowing owl conservation.
2. The Implementing Entity will preferentially select parcels that are closer (i.e., within 0.5 mile) to documented nest locations over those that are farther away.
3. Parcels that do not meet criteria 2 (above) may be considered on a case-by-case basis to allow the Implementing Entity to take advantage of unusual opportunities or circumstances<sup>3</sup>.

#### **Habitat Criteria**

The 600 acres of occupied nesting habitat acquired for the Reserve System must have the following:

1. Documented nesting burrowing owls on the parcel in at least one of the previous 3 years. Parcels that are currently occupied should be selected first, followed by parcels that have been occupied in the previous 3 years.

---

<sup>3</sup> It is not the intent of the burrowing owl conservation strategy to permanently protect or permanently manage lands in urban areas that are anticipated to be developed (e.g., the North First Street area of San José).

2. Be surrounded by at least 140 acres of foraging habitat within 0.5 mile of a nest site (including the parcel where nesting was documented). If there is no potential for foraging habitat to be protected through future acquisition, conservation easement, or management agreement, the nest site should not be acquired unless long-term viability of the site can be in some other way demonstrated.
3. Currently supports ground squirrels or is located adjacent to another parcel with ground squirrels.
4. Currently support grassland, barren, or other land cover types that can be managed or modified to enhance the site to increase the habitat quality for burrowing owls.

## Parcel Criteria

All parcels considered for inclusion in the Reserve System and managed as burrowing owl habitat will meet the following criteria.

1. Parcel size is not a limiting factor on burrowing owl occupancy, however larger parcels will be favored over smaller parcels to maximize the benefits of conservation funding that will be generated under the Habitat Plan. Larger parcels will support more burrowing owls over the long term and provide both nest sites and foraging habitat. Further, larger parcels allow for more options for important management practices (e.g., grazing with sheep is more practicable on a larger parcel than on a smaller one).
2. Adjacent land uses should not constrain necessary management (e.g., seasonal mowing, winter disking, grazing, or other methods of vegetation removal). Fencing around the parcel must be feasible to control human and animal access. Control of non-native predators (e.g., feral cats, foxes) must also be feasible on the site.
3. Ground squirrel management will not occur on the parcel (see above), so adjacent land uses should be such that ground squirrel control will not be needed (e.g., levees, dams, ranchlands where ground squirrels are not desired).

## M.5 Management Techniques and Tools

The general principles for grassland management will be followed in all grassland or barren areas (Section 5.3.3, *Grassland Conservation and Management*). Management techniques may include any or all of those outlined in Section 5.3.3 *Grassland Conservation and Management*; however, those that will be most beneficial to burrowing owls are grazing and mowing.

Enhancement of sites supporting nesting or overwintering will include maintaining a maximum Effective Height of 5-inches (Green and Anthony 1989).

There are two time periods when this is important, before February 1<sup>st</sup>, so the grasses at the site will be short when owls are selecting nest sites, and following the growing season (dependent on rainfall), so grasses will remain short until the next growing season. Burrowing owl management areas will be assessed monthly to determine if additional mowing treatments are needed to meet the maximum Effective Height of 5-inches requirement. Further, all nesting and overwintering locations that are managed will have restrictions on California ground squirrel control (GRASS-5). On sites where owls are not currently nesting but where attracting owls is consistent with management goals and where California ground squirrels are not present, artificial burrows will be installed to make breeding and wintering sites available immediately for burrowing owls (GRASS-9) (Barclay 2008). Artificial burrows will be used as a temporary measure to encourage use by burrowing owls while long-term measures such as ground squirrel population enhancement are developed and implemented.

Grazing can be used to reduce the biomass or effective height of nonnative invasive species and to maintain structural heterogeneity within the natural community. Grazing is beneficial to burrowing owls because it keeps the vegetation short. Short vegetation is necessary for a site to serve as functional nesting habitat for burrowing owls. Most of the grazing in the permit area will be by livestock (GRASS-6). In some urban areas grazing with goats or sheep may be a better approach.

In some instances, mowing is a reasonable alternative to grazing, and mowing in selected areas is often an option when grazing is infeasible (e.g., urban sites) (GRASS-8). Mowing can also be safer and easier to implement on small isolated parcels, which suits burrowing owls better than any other covered species. In either case the goal of vegetation management will be to reduce the overall height and Effective Height of vegetation on burrowing owl habitat to optimal conditions for the species (GRASS-8). Deep ripping will not be performed in the Reserve System or management areas for the burrowing owl because it often destroys burrows and increases soil erosion. Using light disking outside of the nesting season may be used in select cases. The use of light disking will be evaluated on a case-by-case basis and will be used only when other forms of vegetation removal are not practical. Disking does not result in re-contouring of the landscape and will not affect site hydrology.

The Implementing Entity will allow and encourage colonization by California ground squirrels in managed grasslands and barren lands, excluding engineered levees and dams. This expansion of colonies will be monitored and only allowed in areas where conflicts with covered activities will be minimized (GRASS-5). To facilitate this expansion of California ground squirrel colonies the Implementing Entity will cease using rodenticides on managed lands except when needed to protect the integrity of structures such as levees and dams (reservoirs or stock ponds) or to prevent nuisance (as defined in the Fish and Game Code Sections 4150 and 4152) populations on adjacent private lands (GRASS-5). This may include relocating ground squirrels from areas where they are less desirable (dams, levees, golf courses, etc.) into areas where they are needed and their presence is compatible with surrounding land uses.

## M.6 Threats and Uncertainties

Burrowing owls have been reluctant to disperse very far from their natal burrows within Santa Clara County (J. Barclay pers. comm.). A conservation strategy that depends on individual owls dispersing from known breeding sites (e.g., San José International Airport) to newly protected sites is uncertain. Further, the success of the burrowing owl population at San José International Airport is not guaranteed over the long term. Should the breeding population at San José International Airport be reduced significantly in the future there will be far fewer burrowing owls to recolonize these newly protected areas.

The second most vigorous burrowing owl breeding population in the study area is at the San Jose/Santa Clara Water Pollution Control Plant buffer lands. Management of this area has varied in the recent past and there is no long-term guarantee that the burrowing owl population will persist at this site. Planned development of portions of this site would result in the loss of burrowing owl habitat.

Though habitat is managed for burrowing owls at several locations there are still uncertainties with these management programs. Changes in current management practices that benefit burrowing owls at Moffett Airfield, Shoreline Park, VTA's Cerone bus yard, and Mission College continue to be uncertain and planned future development at any of these sites would be a threat to burrowing owls and their habitat.

## INTRODUCTION

The Santa Clara Valley HCP/NCCP (Plan) contains the biological goal and objective of increasing the size and distribution of the burrowing owl (*Athene cunicularia*) population in the Plan area. Implicit in this goal is the assumption that increasing the size and distribution of the burrowing owl population will increase the likelihood that a population of owls will persist into the future through the 50-year term of the Plan. This goal invites examination of the question of how large the burrowing owl population in the Plan area has to be so it has an acceptably high probability of persistence. This report contains a quantitatively-informed examination of this question by using count-based population viability analysis (PVA) techniques of three of the largest extant burrowing owl colonies in the Santa Clara Valley at Mineta San Jose International Airport (SJC), NASA Ames Research Center/Moffett Field (Moffett), and Shoreline at Mountain View (Shoreline).

Results of the statewide burrowing owl survey in 1991-1993 (DeSante et al. 1997, 2007), and surveys for nesting burrowing owls in the Plan area in 2000 (Albion Environmental, Inc. 2000) and 2008 (Albion Environmental, Inc. 2008) suggest the population of nesting burrowing owls in Santa Clara County has declined in recent decades (also see discussion in Townsend and Lenihan 2007). Conclusions about the magnitude of decline have been based on different sources of information including anecdotal evidence from previous years (DeSante et al. 1997, 2007, Townsend and Lenihan 2007) or changes in abundance at individual colonies (Barclay 2007 for SJC; Trulio 1997 and Trulio and Chromczak 2007 for Moffett and Shoreline). DeSante et al. (1997, 2007) estimated the San Francisco Bay area burrowing owl population from 153 -165 pairs in the early 1990s and suggested a 50% decline since the late 1980s. Information about owl abundance in the City of San Jose also suggested an approximately 50% decline: from 43-47 pairs in 1997, to 39-40 pairs in 2000 and 20-21 pairs in 2008. To date there has been no quantitative analysis of population growth rate and variance using the same analytical method for the three best-studied burrowing owl colonies in Santa Clara County.

The goals of this analysis are to:

1. Quantify population size, growth rate and variance in the burrowing owl colonies at SJC, Moffett, and Shoreline in recent years,
2. Evaluate the probability of persistence of these colonies (individually and combined) using population growth and variance over recent years, and
3. Make an informed recommendation about how the conservation measures for burrowing owls could be constructed to increase the chances of meeting the Plan's biological goals and objectives for burrowing owls.

## METHODS

I used count-based PVA methods described by Dennis et al. (1991), Morris et al. (1999), and Morris and Doak (2002) using annual counts of adult (i.e.,  $\geq 1$  year old) burrowing owls recorded during the early part of the nesting cycle at SJC, Moffett, and Shoreline for the years shown in Table 1. Assumptions of count-based PVA include (Morris et al. 1999, Morris and Doak 2002):

1. The data represent exhaustive counts of a subset of individuals (i.e., adults) comprising a fraction of the entire population that does not change over time.
2. Year-to-year variation in the counts reflects the true magnitude of environmentally-driven variation, censuses were performed in a sufficient number of years (at least 10) to accurately assess year-to-year variation in population growth rate, and variation in counts must not be due primarily to observation error in estimating population size each year.
3. Inter-annual environmentally-driven variation is not extreme and there are no large-magnitude fluctuations caused by extreme catastrophes or unusually good years.
4. The population growth rate is not affected by density and does not change as the population increases or decreases.

Other conditions that affect the precision of estimates of persistence include the absence of autocorrelation (e.g., an increase following an increase or decline following decline) and no significant change in the growth rate over time (Morris and Doak 2002).

Implicit in this analytical technique is the assumption that environmental effects on vital rates (i.e., birth rates and death rates) and immigration and emigration are summarized in annual numbers of adult owls (Morris and Doak 2002).

Annual (t) population growth rate  $\lambda$  (lambda) was calculated as:

$$\lambda_t = N_{t+1}/N_t$$

Where  $N_t$  = number of adult owls in year t.

The geometric mean of  $\lambda$  ( $\lambda_G$ ) expresses population growth and is the value that gives the same average annual population growth rate as observed over a long sequence of stochastically varying growth rates (Morris and Doak 2002). The geometric mean is used because it better represents exponential growth of populations than the arithmetic mean. Stochastic population growth  $\mu$  (mu) was calculated as:

$$\mu = \log \lambda_G \approx (\log \lambda_t + \log \lambda_{t-1} + \log \lambda_{t-2} + \dots + \lambda_2 + \lambda_1 + \lambda_0) / t$$

The variance in the rate at which  $\mu$  changes over time is expressed as  $\sigma^2$  (sigma squared) and is approximated by the variance of the  $\log \lambda_t$  values (Morris and Doak 2002).

These equations predict that if  $\mu > 0$ , then  $\lambda_G > 1$ , and most population trajectories will grow and if  $\mu < 0$ , then  $\lambda_G < 1$ , and most trajectories decline. The more the population growth rate  $\lambda$  varies from year to year as a result of environmental and demographic stochasticity the greater will be the value of  $\sigma^2$  and the greater the range of possible population sizes in the future (Morris and Doak 2002). Greater variance leads to less precise predictions of persistence (Morris and Doak 2002).

The probability of a population with parameters  $\mu$  and  $\sigma^2$  reaching a user-defined extinction threshold (i.e., quasi-extinction threshold) is based on diffusion approximation theory and the cumulative distribution function (CDF) (Morris and Doak 2002). The quasi-extinction threshold is a selected number for the purpose of comparing relative extinction risk of two or more populations rather than predicting when the last individual dies and the population is functionally extinct, which becomes

imprecise with time (Morris and Doak 2002). Dennis et al. (1991), Morris et al. (1999), and Morris and Doak (2002) discuss the theoretical underpinnings of extinction approximation and CDF.

### **Annual number of adult burrowing owls**

Annual numbers of adult burrowing owls at SJC represent the number of adult owls recorded in March or April as reported in annual breeding burrowing owl reports for SJC (Albion Environmental, Inc. 1997-2009, Barclay 2007). I selected the number of adult burrowing owls at Moffett from data supplied by C. Alderete (PAI Corporation) and the number of adult owls in March or April from data supplied by S. Kleinhaus (Santa Clara Valley Audubon Society) for Shoreline (Table 1, Figure 1).

I performed count-based PVA for each colony for the respective time periods for which adult count data were available (Table 1, Figure 1). I also analyzed a combined data set consisting of annual numbers of adult owls at SJC, Moffett, and Shoreline for the 11 year period 1999-2009 when adult count data were available for all three colonies (Table 1). For comparison to show a different growth rate for a similar-sized burrowing owl colony approximately during the same time period, I conducted the same analysis of adult burrowing owls at Sharpe Depot in San Joaquin County during 1997-2009 (Albion Environmental, Inc. annual breeding burrowing owl census reports, 1997-2009).

I simulated population growth in the Santa Clara County owl population by increasing the total population of adult owls (as of 2009), instantaneously and incrementally over time. Increasing the population enabled evaluation of the influence of future Plan conservation measures to support a larger burrowing owl population and how simulated population growth affected population persistence. Analyses were done with a count-based PVA tool obtained from Sinauer Associates (www.sinauer.org obtained October 2009).

## **RESULTS**

### **Trends**

Each of the burrowing owl colonies at SJC, Moffett, and Shoreline showed declining trends (i.e.,  $\mu < 0$ ) over their respective time periods (Table 1, Figure 1). SJC and Moffett showed very similar magnitudes and variance of decline compared to Shoreline that showed a greater magnitude and variance of decline (Table 1). However, the 95% confidence limits (CL) of decline ( $\mu$ ) for each colony ranged from negative to positive (i.e., spanned equilibrium) (Table 1).

The combined numbers of adult owls in all three colonies for the 11-year period 1999-2009 also showed a declining trend and relatively high variance (i.e.,  $\sigma^2 \geq 2\mu$ , Morris and Doak 2002) (Table 1).

### **Probability of persistence**

The colonies at SJC and Moffett showed similar probabilities of persistence represented by the mean and 95% CL of the probability of reaching a quasi-extinction threshold of two adult owls (Figure 2). These two colonies showed similar probabilities of quasi-extinction at 50 years: 0.5293 (0-0.9936) at SJC and 0.5256 (0-0.9954) at Moffett (Table 1). Shoreline showed a higher probability of reaching the quasi-extinction threshold of two adults (Figure 2), due to the smaller size of this colony and greater decline and variance (Table 1).

The probability of quasi-extinction, set at six adults (representing two adults at each colony) for the combined counts (Figure 3) was slightly higher (0.06909, 0-0.996) than for the individual colonies at SJC and Moffett (Table 1).

## DISCUSSION

As an example of the effect of a positive growth rate ( $\mu$ ) on population persistence Figure 4 shows annual counts of adult burrowing owls at Sharpe Depot in San Joaquin County for 1997-2009 (Albion Environmental, 1997-2009). The mean probability of persistence coincides with the x-axis (i.e., zero) although the 95% CL show that this colony still has a fairly high probability of quasi-extinction (2 owls) with time (95% CL ~ 90% at 50 years), due to the wide confidence limits of  $\mu$  (-0.1070 – 0.2225) and variance ( $\sigma^2 = 0.0672$ ) (Figure 4).

In order to evaluate the effect of population size on population persistence, I experimentally doubled the combined 2009 population of adults at the three colonies (51 adults, Table 1) to 102 and show the probability of persistence CDF in Figure 5 (top). The best estimate of reaching the quasi-extinction threshold in 50 years is 0.5363 (95% CL 0 – 0.991). Because doubling the population size did not substantially lower the probability of quasi-extinction (compare with Figure 3 bottom) I increased the population to 204 (i.e., 4 x the 2009 population) and show the probability of quasi-extinction CDF in Figure 5 (bottom). In this case the best estimate of quasi-extinction in 50 years declined to 0.3836 (95% CL 0-9982).

While increasing population size lowered the mean probability of extinction, the 95% confidence limits still approach 100% in about 30 years (Figure 5). These analyses show that population size alone does not increase the probability of persistence to an acceptably high level. One of the reasons is that instantaneously increasing population size does not reverse the declining trend from the previous 11 years in the three major colonies during 1999-2009 (Table 1). This suggests that in order for burrowing owls to have a higher probability of persistence during the 50-year term of the Plan the population growth rate will have to change from a decreasing trend ( $\mu < 0$ ) to an increasing trend ( $\mu > 0$ ).

To assess how long it might take to achieve a positive growth rate, I incrementally increased the population at the three colonies combined (51 adults) in 2009 by three percent per year (rounded to whole integers) until  $\mu$  changed to positive. Figure 6 shows that it took 16 years of three percent increase per year to obtain a positive growth rate. The probability of quasi-extinction CDF of the resulting population (Figure 6 bottom) shows how a positive growth rate increases the chances of population persistence.

## RECOMMENDATIONS

The PVA of burrowing owls in the Santa Clara Valley demonstrates that population persistence is not based solely on numbers, but rather it will be necessary to reverse the negative growth rate observed in the three largest local burrowing owl colonies during the last 11 years in order to reduce the probability of extinction to an acceptably low level (Figure 6). To accomplish this, the Plan's conservation goals and objectives should contain provisions to conserve and manage nesting habitat in optimum condition as soon as practicable after Plan approval to enable the local burrowing owl population to increase.

Second, the Plan should contain a detailed annual monitoring protocol (Morris et al. 1999, Morris and Doak 2002) designed to yield thorough annual counts of adult owls at a consistent subset of locations occupied by nesting burrowing owls. These could include colonies at SJC, Moffett, Shoreline, Alviso area, Mission College, Warm Springs District. Annual adult counts at a consistent subset of breeding sites should be included in annual on-going count-based PVA updates to enable monitoring of population trend and variance during the term of the Plan. Finally, success criteria for burrowing owl conservation in the Plan should be evaluated in terms of annual adults and annual monitoring of the growth rate ( $\mu$ ).

Figure 2. Probabilities of the burrowing owl colonies at SJC, Moffett, and Shoreline reaching a quasi-extinction threshold of two owls based on cumulative distribution function (CDF).

Figure 3. Combined counts of adult burrowing owls at SJC, Moffett, and Shoreline for the years 1999-2009 (top graph) and probability of the combined population reaching a quasi-extinction threshold of six owls (bottom graph): mean  $\lambda = 0.9547$  (95% CL 0.7672 - 1.1881),  $\mu = -0.0462$  (95% CL -0.2649 - 0.1724),  $\sigma^2 = 0.0934$ .

Figure 4. Adult burrowing owl counts at Sharpe Depot from 1997-2009 (top graph) and probability of the colony reaching a quasi-extinction threshold of two owls (bottom graph): mean  $\lambda = 1.0595$  (95% CL 0.89840 – 1.2492),  $\mu = 0.0577$  (95% CL -0.1070 – 0.2225),  $\sigma^2 = 0.0672$ ).

Figure 5. Probability of the adult burrowing owl population at SJC, Moffett, and Shoreline in 2009 (51 adults) increased 2 x (top graph) and 4 x (bottom graph) of reaching a quasi-extinction threshold of six owls.

Figure 6. Adult burrowing owls at SJC, Moffett, and Shoreline 1999-2009 artificially increased 3% per year to achieve  $\mu > 0$  (top graph) and probability of the resulting population: mean  $\lambda = 1.0009$  (95% CL 0.9279 – 1.0796),  $\mu = (0.0009$  (95% CL -0.0747 – 0.0766),  $\sigma^2 = 0.0351$ , reaching a quasi-extinction threshold of six owls.

## **List of Acronyms and Abbreviations**

# List of Acronyms and Abbreviations

°C	degrees Centigrade
°F	degrees Fahrenheit
ADA	Americans with Disabilities Act
ATV	all-terrain vehicles
BA	biological assessment
BAAQMD	Bay Area Air Quality Management District
BCDC	Bay Conservation and Development Commission
BMPs	best management practices
BO	biological opinion
Cal-Fire	California Department of Forestry and Fire Protection
Caltrans	California Department of Transportation
CCR	California Code of Regulations
CDF	California Department of Forestry and Fire Protection
CDFG	California Department of Fish and Game
CEQA	California Environmental Quality Act
CESA	California Endangered Species Act
CFR	Code of Federal Regulations
cfs	cubic feet per second
CMAQ	Community Multiscale Air Quality modeling system
CNDDDB	California Natural Diversity Database
CNPS	California Native Plant Society
Corps	U.S. Army Corps of Engineers
County	Santa Clara County
County Parks	County of Santa Clara, Parks and Recreation Department
CPI	Consumer Price Index
County Parks Strategic Plan	Strategic Plan for the Santa Clara County Parks and Recreation System
CSC	California species of special concern
CWA	Clean Water Act
CWMZs	Cold Water Management Zones
DEM	Digital Elevation Models
DSOD	California Division of Safety of Dams
Eagle Act	Bald and Golden Eagle Protection Act
EIR	environmental impact report
EIS	environmental impact statement

EIS/EIR	environmental impact statement/environmental impact report
EPA	U.S. Environmental Protection Agency
ESA	federal Endangered Species Act
FAA	Federal Aviation Administration
FAHCE	Fisheries and Aquatic Habitat Collaborative Effort
FEMA	Federal Emergency Management Agency
FERC	Federal Energy Regulatory Commission
FR	Federal Register
GIS	geographic information systems
HCP	habitat conservation plan
HPI	Home Price Index
I-680	Interstate 680
IA	implementing agreement
IPM	integrated pest management
JPA	Joint Powers Authority
km <sup>2</sup>	square kilometers
LAFCO	Local Agency Formation Commission
LAIF	Local Agency Investment Fund
MBTA	Migratory Bird Treaty Act of 1918, as amended
MIG	Moore Iacofano Goltsman
MIST	minimum impact suppression tactics
Moore Foundation	Gordon and Betty Moore Foundation
MOU	memorandum of understanding
msl	above mean sea level
NCCP	natural community conservation plan
NCCP Act	Natural Community Conservation Planning Act
NEPA	National Environmental Policy Act
NFWF	National Fish and Wildlife Foundation
NHPA	National Historic Preservation Act
NMFS	National Marine Fisheries Service
NO <sub>2</sub>	nitrogen dioxide
NOAA	National Oceanic and Atmospheric Administration
NO <sub>x</sub>	oxides of nitrogen
NPDES	National Pollutant Discharge Elimination System
NWI	National Wetlands Inventory
Open Space Authority	Santa Clara Valley Open Space Authority

Packard Foundation	David and Lucile Packard Foundation
PAR	Property Analysis Report
PG&E	The Pacific Gas and Electric Company
Plan	Santa Clara Valley Habitat Plan
POST	Peninsula Open Space Trust
PVA	population viability analysis
Regional Boards	Regional Water Quality Control Boards
RGP	Regional General Permit
SCADA	supervisory control and data acquisition
SCJAP	South County Joint Area Plan
SCVWD	Santa Clara Valley Water District
Semitropic	Semitropic Water Storage District
SFPUC	San Francisco Public Utilities Commission
SOD	sudden oak death
SR	State Route
SRA	Shaded Riverine Aquatic
State Board	State Water Resources Control Board
State Parks	California Department of Parks and Recreation
Three Creeks HCP	Three Creeks Habitat Conservation Plan
TMDLs	Total Maximum Daily Loads
TNC	The Nature Conservancy
U.S.	U.S. Highway
UGB	urban growth boundary
ULL	urban limit line
USA	urban service area
USB	urban service boundary
USC	U.S. Government Code
USDA	U.S. Department of Agriculture
USFWS	U.S. Fish and Wildlife Service
USGS	U.S. Geological Survey
UTC	United Technologies Corporation
VTa	Santa Clara Valley Transportation Authority
VTM	Vegetation Type Map
VTP 2035	Valley Transportation Plan 2035
Wildlife Agencies	U.S. Fish and Wildlife Service and California Department of Fish and Game
